FOOD.

FOOD *of* PLANTS, in *Agriculture* and *Vegetation*, the various kinds of fine attenuated and elaborated materials which are abſorbed from the ſurrounding atmoſphere, or taken up from the ſoil, in order to their nouriſhment and ſupport. It ſeems not improbable but that many of the more fluid and elaſtic matters of nature may contribute in this way. The more ancient writers were extremely anxious to aſcertain the nature of the *pabulum*, or food of plants, but their inquiries on the ſubject were far from ſatisfactory. They aſcribed the growth and increaſe of plants to ſeveral different matters, as water, air, earth, fire, &c.; and even to the neutral ſalt, known by the name of nitre. But they were not able to ſhew which of them was properly the food of plants. Van Helmont was ſtrongly in favour of water; Bradley contended for its being air, while Lawrence and others ſupported the opinion of its depending on fire. And a great number of more modern authors have ſtood forward in ſupport of earth, and nitre as the food of plants. The matter, however, continued in this unſettled ſtate, until the improvements of the French chemiſts threw additional light upon it, by ſhewing that various gaſeous, liquid, carbonaceous, and other ſubſtances, either in their ſimple or combined ſtates, were eſſential to the nouriſhment and ſupport of vegetable life.

Further inquiries into the nature and principles of vegetation, and the manner in which it is performed, are however highly deſerving of the attention of thoſe who are engaged in the cultivation of the ſoil, as upon the knowledge of theſe in a great meaſure depends, not only the improvement of huſbandry, but the advantageous production of different ſorts of plants, as crops. The agriculturaliſt ſhould indeed be in poſſeſſion of the full and complete knowledge of the means by which all the various ſorts of uſeful field plants are beſt capable of being raiſed, ſupported, and brought to perfection. A juſt and exact notion of theſe muſt contribute greatly in directing and aſſiſting him in the care and management of his lands and crops, as well as in ſhewing the moſt advantageous ſtates and conditions of the ground for affording the nouriſhment and ſupport of the plants, in the moſt eaſy, abundant, and expeditious manner.

The reſearches of doctor Ingenhouſz throw conſiderable light not only on the nature of the food of plants, but likewiſe on the renovation and improvement of ſoils. It is contended by this ingenious philoſopher, in an able eſſay, inſerted in the thirty-ſeventh volume of the Annals of Agriculture, that the ſureſt way of finding out the real nouriſhment of organized bodies, ſeems to be to inquire what is the ſubſtance without which they inevitably periſh, and which alone is ſufficient to continue their life. All animals require two ingredients for the continuation of their exiſtence; *viz.* atmoſpheric air, and moiſt food, derived either from animal or vegetable ſubſtances; which food being received into the ſtomach or ſome reſervoir deſtined for that purpoſe, and being gradually digeſted and changed into different ſubſtances in the different organs, is applied to the whole economy of the animal body. Vegetables being deprived of progreſſive motion, by which means the greateſt number of animals go in ſearch of food, muſt find in the narrow compaſs or ſpace they occupy every thing neceſſary for their ſubſiſtence. As they are in contact with two ſubſtances only, the earth and the atmoſpheric air, their nouriſhment muſt, he thinks, exiſt in either of them, or in both. The earth is neceſſary to the plants, as the only means to fix them ſtedfaſtly to the ſpot, by ſpreading through it their roots; but as earth contains generally moiſture, ſalts, air, &c. nature has taken advantage from this circumſtance, ſo that the filaments of the roots pump from the ſoil all that is

Stuahan and Preſton,
New-ſtreet Square, London.

is offered to their ſuckers, and can be abſorbed by them; but as ſome plants may live and thrive without being in contact with any earth, we ought to take it for granted, that the ſoil, or what exiſts in the ſoil, is not the only food of plants. Water is neceſſary to all organized beings, as without it no circulation of juices could be carried on, but from this neceſſity it can only be deduced that water is a vehicle of the food, and by no means that it is the true nouriſhment of animals or vegetables; the leſs ſo, as it is an incontrovertible fact that ſeveral plants can live without being in contact with water. Thus the agave, cactus, aloe, cacalia, &c. live on the moſt dry rocks in the hotteſt climates, where it does not rain ſometimes in the ſpace of ſeveral months, and where the burning ſun pierces all other plants, and even deprives the trees of all their leaves, and what is extraordinary, almoſt all the parts of ſuch plants are full of juices. The nocturnal dew, it is ſuppoſed, cannot give ſufficient nouriſhment to ſuch plants, as all other plants would alſo maintain themſelves with it. But to be certain that thoſe plants do not ſubſiſt by dew, we ought to conſider only that ſome plants of that ſpecies may be kept alive in the hot houſes, either in pots, without being watered, or by hanging them up from the cieling. Now, as by what he has ſaid here, it ſeems, the writer thinks, to be probable, that neither water nor ſoil is or contains all the true nouriſhment of vegetables, it muſt be concluded, that plants muſt find it in the atmoſpheric air, for this, it is aſſerted, is the only ingredient, without which all vegetables periſh. A plant ſhut up in vacuo ſoon dies, and it dies in all ſorts of aerial fluids, which are incapable of ſupporting animal life; ſuch as carbonic acid gas, or fixed air, hydrogen gas, or inflammable air, phlogiſticated air, or azote, &c. It is true, he admits, that doctor Prieſtley and Mr. Scheele have propagated a doctrine diametrically oppoſite to what he has here advanced, by ſaying that plants thrive wonderfully in putrid air, and periſh in pure or dephlogiſticated air. This doctrine, though generally adopted, and very ingeniouſly applied by ſir John Pringle and others to illuſtrate the mutual reſemblance eſtabliſhed by the author of nature between the vegetable kingdom, and the animal creation, is, it is conceived, refuted by his experiments, by which he thinks, he has proved, that plants ſhut up in vital air live ſo much the longer, as this air is ſuperior in purity to atmoſpheric air. In his "Expériences ſur les Végétaux," tome ii. he has explained the manner of making theſe experiments with ſucceſs; and has ſhewn the reaſon why, of two plants, the one ſhut up with common air, the other with the ſame quantity of vital air, (both kept in the dark,) the plant placed in common air can only be kept alive during a certain very limited time, whereas the plant ſhut up in vital air may be kept alive much longer, even as long as there is vital air enough remaining to cover the whole plant.

From theſe and many other conſiderations, he has deduced that from the two organized kingdoms, the animal and the vegetable, the animal derives its nouriſhment from the vegetable; but that the vegetable creation is independent of the animal world, provides for itſelf, and derives its ſubſiſtence chiefly from the atmoſphere.

It is ſtated, that when he engaged in the experiments on vegetables, which he publiſhed in 1779 in Engliſh, and in 1780 more fully in French, Dr. Prieſtley had already obſerved, that vegetables poſſeſſed a power of correcting bad air; which however was denied by Mr. Scheele in Sweden, who found that plants, inſtead of correcting bad air, corrupted good air. This contradiction ſtruck Dr. Prieſtley ſo much, that he employed the ſummer of 1778 in repeating his former experiments; and after the moſt accurate reſearches he concluded, that though there ſeems to be ſuch a power in plants, yet that very often they have quite a contrary effect, as Mr. Scheele found; but that he did not know what the reaſon of this uncertain effect of plants on air was. In 1778 he found, by accident, that by expoſing well-water a long while to the ſun, it produced a filmy greeniſh ſediment, which produced pure air in the ſunſhine: by examining this matter with a microſcope, he found it deſtitute of organization, and pronounced it to be neither an animal nor a vegetable ſubſtance, but a ſubſtance *ſui generis*, to which he gave the name of green matter. M. Berthollet found alſo, that by expoſing dephlogiſticated marine acid to the ſun, vital air was produced; and Mr. Scheele in Sweden found that the ſame air was alſo produced from nitrous acid, expoſed to the light of the ſun. Dr. Ingenhouſz aſſerts, that he was fortunate enough to diſcover the true reaſon why plants did ſometimes correct bad air, and ſometimes made it worſe, which reaſon was never ſo much as even ſuſpected by either of the above-mentioned philoſophers. He diſcovered, in the ſummer of 1779, that all vegetables are inceſſantly occupied in decompoſing the air in contact with them, changing a great portion of it into carbonic acid gas or fixed air, which being ſpecifically heavier than atmoſpheric air, tends naturally to fall downwards, and being miſcible with moiſture, ſalts, and different ſorts of earthy ſubſtances, is apt to combine with them. He alſo found that the roots, flowers, and fruits, are inceſſantly employed in this kind of decompoſition, even in the middle of the ſunſhine; but that the leaves and green ſtalks alone ceaſe to perform this operation during the time the ſun, or an unſhaded clear day light, ſhines clear upon them, during which time they throw out a conſiderable quantity of the fineſt vital air, and moreover make the air in contact with them purer, or more approaching to the nature of vital air. He has indeed ſtated facts which prove that vital air, produced by vigorous plants in the ſunſhine, is of the greateſt purity in itſelf; and that the air thrown out by them in the ſhade, or in the dark, is in itſelf, that is to ſay, being free from other air, the moſt active poiſon in deſtroying animal life yet known.

He does not doubt but that this continual decompoſition of atmoſpheric air muſt have a general utility for the ſubſiſtence of the vegetables themſelves, and that they principally derive their true food from this operation, by changing this decompoſed air into various juices, ſalts, mucilage, oils, &c. much the ſame as in graminivorous animals, the ſimple graſs changes in the various organs, into the numerous and very heterogeneous fluids and ſolids. It would, however, he thinks, be a very difficult, if not impoſſible taſk, to give a clear and ſatisfactory theory, by which theſe various changes, compoſitions, decompoſitions, new combinations, &c. performed upon one ſingle ſpecies of food, ſuch as graſs, may be explained. The ſame incomprehenſible transformations are going on in vegetables. If once it was ſatisfactorily proved, that plants can ſubſiſt in what they find in atmoſpheric air without any other ſubſtance, we ought, he thinks, to content ourſelves with the fact alone; for it would be in vain to attempt to penetrate the myſtery of all the changes this air undergoes in the organs of theſe living beings; no more need we wiſh anxiouſly to inveſtigate by what means, in a man who lives only on rice and water, all the various tranſmutations of this ſimple food are performed. This myſtery is, it is ſuppoſed, above the reach of our very limited underſtandings. The new light which chemiſtry has received in our age, affords us the means of underſtanding many phenomena which we were either ignorant of,

of, or which nobody underſtood any thing of before. The new diſcoveries in the nature of water, air, ſalts, &c. open the door to an infinite number and variety of new diſcoveries. The identity of the ſame principle of all acids, called oxygen, which the French chemiſts have eſtabliſhed, throws new light on the difference which exiſts in the various acids already known, and on the changes which theſe acids undergo. Thus, the ſame acidifying principle attaching itſelf to a different baſis, becomes either nitrous, vitriolic, marine, or any other acid. With carbon it becomes fixed air, or carbonic acid gas, with ſulphur it becomes vitriolic or ſulphuric acid; with phoſphorus it becomes phoſphoric acid; with azote it becomes nitrous acid, &c. The laſt was a diſcovery made by Mr. Cavendiſh. It may thus, the writer thinks, be reaſonably ſuppoſed, that ſome acids taken into our body may loſe in the various operations of our organs their former radical and combine with a new one, and by this combination entirely change their nature. Without ſuch like changes taking place in our organs, how could we account for the generation of the great quantity of phoſphoric acid exiſting almoſt every where in our bodies, (which acid has already got the name by ſome eminent chemiſts of *animal acid*,) principally in our bones? Whereas we find no where the marine acid, though of all acids we take in the greateſt quantity of it. We find in ſeveral liquids its baſis, the foſſil alkali; as in bile, urine, &c.: but we find nothing of its acid, nor even the marine ſalt undecompoſed, except in the ſerum of the blood, and the *chylus*, in which this ſalt has not yet undergone the elaboration of the vital organs. It ſeems, therefore, as if all the acids, the marine, the vegetable, the carbonic, &c. were in our organs transformed, for the greateſt part, into the animal or phoſphoric acid. It appears, at leaſt, probable, that without ſuppoſing this change of acids to take place in our bodies, we could not account for the great abundance of phoſphoric acid exiſting in our bodies; for though it really exiſts in ſome of our foods, yet the quantity of it is but trifling.

It is farther contended that if plants imbibe fixed air, or carbonic acid gas, it is not more difficult to believe that this ſubſtance may be transformed, elaborated, or modified into various other ſubſtances and ſalts in the organs of the plants, than it is difficult to believe that the above-mentioned changes take place in the human body. Who can believe, without demonſtrative proof, that the aerial fluid, the carbonic acid gas, conſtitutes about $\frac{40}{100}$ of limeſtone; and that this ſtone having loſt its hardneſs, by being deprived of this aerial fluid, regains its former conſiſtency by recovering this fluid? As the carbonic acid is compoſed of the acidifying principle, the oxygen, and the carbon or coal, plants may derive from theſe two principles ſome of the moſt eſſential ſubſtances we find in them; their acids, their oils, their mucilage, &c.; theſe ingredients, together with the azote abſorbed alſo with the atmoſpheric air, being elaborated in their organs, ſomewhat analogous to the wonderful, though to the human underſtanding incomprehenſible, elaborations and combinations which we obſerve in the bodies of animals. M. Haſſenfratz's three papers on the nouriſhment of plants, delivered in 1792 to the Royal Academy of Paris, have met with very general approbation; and the principal part of the doctrine contained in them, *viz.* that *coal*, or carbon, *conſtitutes the principal nutritive ſubſtance of plants*, has been adopted by the celebrated Mr. Kirwan, in his "Diſſertation on Manures," ſome time ſince preſented to the attention of the agriculturaliſt.

In the firſt it is contended that water and air are not alone ſufficient to nouriſh plants, but that the developement or growth of theſe matters is owing to the carbon, which, being originally lodged in the ſeed, is expended in this buſineſs. In the ſecond, the writer attempts to prove that the carbonic acid, or fixed air, is not a nutritive ingredient of plants, and that the act of vegetation does not decompoſe the carbonic acid; but, on the contrary, this carbonic acid is, as Dr. Ingenhouſz has diſcovered, formed by plants in the dark, and drawn from the plants and the oxygen of the water decompoſed by vegetables. Mr. Kirwan, however, differs in this reſpect from M. Haſſenfratz, and thinks that the carbonic acid is decompoſed by the act of vegetation. In the third paper, it is aſſerted that the carbon, the true nouriſhment of plants, is derived by the roots from the ſoil, where it is found ready in a ſtate of ſufficient ſolution or ſuſpenſion to be abſorbed by the ſuckers, and carried through the whole plant. It is thought that the vigour of the plants depends chiefly upon the quantity of carbon with which the ſoil is impregnated; and the name of carbon is given to the brown ſediment of the infuſion of dung which remains after the water is evaporated or conveyed away by the action of heat, &c.

But the doctrine contained in theſe memoirs, as well as the important experiments to which they relate, require, in Dr. Ingenhouſz's opinion, farther inveſtigation, before it can be proved or clearly underſtood. The following hints and conſiderations may, it is ſuppoſed, perhaps ſhew the way towards the true myſtery of the manner which nature employs to feed the plants. All ſeeds contain a certain quantity of food, by which the plant may be kept alive in the beginning of its growth; ſome have a conſiderable portion of mucilaginous matter, ſuch as the ſeed of quince; ſome have, beſides this mucilage, a very thick cover or pulp, by which the ſeed is ſurrounded, ſuch as the ſeed of grapes, apples, pears, melons, cucumbers, &c. which ſubſtances ſerve alſo as food for animals. All thoſe ſubſtances by which many grains are thickly covered, yield a great quantity of fixed air, or carbonic acid gas, when the ſeed lodged in them begins to vegetate; but this ſubſtance, being exhauſted at the cloſe of their fermentation and putrefaction, the embryo plants muſt be capable of providing for themſelves. A newborn child may alſo live a few days without food, being nouriſhed by ſome nutritious matter which it brings with it when born, and which it had imbibed by the mouth when in the womb, and part of which nouriſhment was prepared in the pectoral gland of the child; as it is well known that all children, male as well as female, come into the world with a portion of true milk elaborated in their breaſts. Thus alſo, the yolk of the egg is drawn into the ſtomach of the chick when ready to break its priſon, by means of which yolk it is nouriſhed till it has acquired ſtrength enough to go in ſearch of food. The mothers of animals, endowed with breaſts, feed, during a certain time, their offspring by their milk. Many animals, ſuch as birds of different kinds, wander about in ſearch of food to be carried to their young. Very few animals find, on the ſpot where they exiſt, every thing they want. But all plants are deſtined by nature to remain on the ſame ſpot, and therefore muſt poſſeſs ſuch faculties as prepare into food ſome of the ſubſtances in contact with them, as ſoon as they have conſumed the ſmall ſtore of food they are provided with before they vegetate. As the very firſt decompoſition of the pulp ſurrounding the ſeeds is accompanied with the production of carbonic acid gas, and the firſt operation of the embryo, or beginning plant, is to decompoſe the air in contact with it, by changing the oxygenous part of it into carbonic acid gas, of which it probably abſorbs, in the

dark and ſhade, the oxygen, and, in the ſunſhine, the carbon, throwing out at the ſame time the oxygen alone, and keeping the carbon to itſelf as nouriſhment; as all theſe different operations have one general effect, *viz.* the decompoſing the air in contact with plants, it ſeems more than probable that vegetables derive their principal food from this decompoſition, and the production of fixed air, or carbonic acid gas. This ſuppoſition will, it is contended, acquire a degree of greater probability by conſidering, that all airs which cannot be eaſily changed or decompoſed into fixed air, as poſſeſſing no oxygen at all, are true poiſons to plants, ſuch as hydrogen or inflammable air, putrid air and azote, contrary to Dr. Prieſtley's and Mr. Scheele's doctrine; and that vital air itſelf, or an air approaching to its nature, maintains a plant remarkably well in its full vigour, and that carbonic acid gas concentrated, or without a great portion of reſpirable air, kills alſo plants, as this air and all other airs, poiſonous to vegetable life, are alſo deſtructive of animal life; which doctrine the writer offered firſt, in contradiction to that of the two celebrated philoſophers juſt mentioned. Dr. Ingenhouſz ſhould, however, have proved the firſt poſition by experiments, in oppoſition to thoſe of Mr. Young and other inquirers, as the firſt has, he aſſures us, fed plants with hydrogen or inflammable air, till they became, comparatively ſpeaking, giants among dwarfs. How then, he aſks, does it act as a poiſon? If nothing elſe be given, it may, as the moſt nutritious food may, ſuffocate animals. Dr. Ingenhouſz, however, ſtates, that when he diſcovered, in 1779, that all vegetables decompoſe the common air by night, and change a part of it into fixed air; and when he drew from this and ſome other facts the concluſion, that the plants abſorb this fixed air and turn it into their nouriſhment, the new doctrine of chemiſtry was not publiſhed; and, being ignorant of all the beauties of that ſyſtem, he was unable to reduce theſe facts to a proper theory: but ſince we have been inſtructed in the analyſis of water and air, it is become, he thinks, much eaſier to explain the phenomena of vegetation. As it is now admitted that fixed air, or carbonic acid gas, is compoſed of oxygen deprived of its caloric, or matter of heat, and of carbon, it is not difficult to underſtand how plants provide or prepare their own nouriſhment by producing carbonic acid, ſuppoſing it to be demonſtrated that carbon is the principal nouriſhment of plants, as hinted above.

It is further ſuggeſted, that from this doctrine it would naturally be inferred, that plants muſt grow the moſt rapidly at ſuch time as they prepare the greateſt quantity of this nouriſhment, which is when they are in the dark; and this is juſt what really happens, as all plants grow with much more rapidity in a dark place than in the light, as M. Du Hamel and M. Bonnet, of Geneva, found. Plants in general grow leſs, it is ſuppoſed, towards the middle of the day than at any other time; many do not advance at all when the ſun is near the meridian; ſome even become manifeſtly ſhorter towards that time of the day.

The writer has alſo diſcovered that the roots of plants, even when expoſed to the ſunſhine, produce carbonic acid gas, but that the leaves and green ſtalks produce this acid only in the dark; and that flowers and fruits, with a few exceptions among the laſt, produce at all times, even at the roots, carbonic acid. Thus there is no time loſt, ſome parts, or the whole plant, being conſtantly employed in this buſineſs of preparing carbonic acid. Though M. Haſſenfratz ſeems to believe that plants do not derive the carbon (in his opinion their true nouriſhment) from the carbonic acid, but find it ready made in the dung; the doctor, however, thinks it more probable that plants derive it chiefly from the carbonic acid, which is a ſubſtance very eaſily decompoſable into its two ingredients, *viz.* oxygen and carbon. All manures, but principally dung, produce a great quantity of carbonic acid either by themſelves, or by decompoſing the air in contact with them. But here, ſays he, ſeems to ſtart up a difficulty, how a plant or manure can draw from the atmoſpheric air carbonic acid, as common air contains, according to the new ſyſtem, only $\frac{1}{100}$ of it, and, according to M. Lavoiſier, none at all. Though, according to theſe principles, it could not be accounted for theoretically, it is thought we have at hand facts enough, from which it ſeems evident, that the common air can by itſelf furniſh all the ingredients for the compoſition of carbonic acid, as we ſhall ſee bye and bye.

It is ſuggeſted, that we are as yet very far from underſtanding the various productions, which in this world are expoſed to our ſenſes as offſprings from the infinite combinations, decompoſitions, chemical affinities or attractions, &c. every where in action, on the ſurface, and in the bowels of the earth, in the atmoſphere, the waters of the ſea, and all others in the organized bodies of animals, vegetables, &c. The new ſyſtem of chemiſtry, indeed, furniſhes a vaſt deal of new light, but is yet by no means ſufficient to penetrate into the deep myſteries of organized beings; for inſtance, the propagation of animals and vegetables has, the writer thinks, acquired from it but very little, if any light at all. But to return to the ſubject of the production of carbonic acid. Calcareous ſtones and alkaline ſalts, deprived of their carbonic acid by fire, regain it ſolely by the expoſure to the open air. If this production can happen by ſuch ſimple means, can we be aſtoniſhed that organized bodies draw it from the ſame ſource, the atmoſphere; which to him ſeems to be the general magazine or ſtore-houſe of all the ſubſtances which enter into the compoſition of all organized bodies of the animal and vegetable kingdom, and even many others of the mineral kingdom in addition.

It is further remarked that M. Du Hamel found that a branch of a vine, or any other tree, conducted within a hot-houſe, its root remaining out of its boundaries, will there ſhoot forth vigorous leaves, new buds, flowers, and produce fruit, when all the other branches remaining expoſed to the open air, ſhew no ſigns of life; being, with their roots benumbed by the cold, and probably deſtitute of any motion or circulation of their juices. If the growth of vegetables depended on the abſorption of carbon by their roots, the branch drawn into a hot-houſe could not, the doctor ſays, thrive at all, as long as the root and ſtem were benumbed by cold weather. But this branch, being in contact with no ſubſtance but air, heat and light, muſt derive from the ſurrounding air alone all it wants, to perform all the operations neceſſary to its growth and propagation. By watching all its phenomena, it will be found decompoſing the air in contact with it, but in a very different way by day and by night; and that it performs theſe tranſmutations of air chiefly within its organs, is the more probable, becauſe all plants abſorb the air in contact with them, with all its contents, and throw it out in a given time much altered from what it was at the moment it was drawn in. The period of time required by a plant to renew all the air it has abſorbed, he found to be leſs than half an hour by day and by night. This laſt aſſertion, which he has demonſtrated by facts, will, he ſuppoſes, perhaps be looked upon by critical minds as ſomewhat paradoxical, as it ſeems difficult to conceive that the ſame organized body can, at the ſame time, inhale and evaporate from the ſame ſurface the ſame fluid; but this double phenomenon being continually performed in all parts of living animals, the difficulty of underſtanding it vaniſhes

of

of courſe. Though the moſt part of animal plants which afford good nouriſhment for men, ſuch as wheat, rye, maize, &c. will grow in poor ſoils, yet they do not become thriving in a luxuriant way, but in what is called a rich or well manured ſoil. Thoſe plants have a quick growth, when aſſiſted by heat and the ſun's light, come very ſoon to their term, or to the act of propagating their ſpecies, or of producing ſeed; which being come to perfection, the vital power of the plant is exhauſted, and it dies. Theſe plants being of a tender ſtructure, and generally not ſpreading their roots deep in the ground, require the niceſt attention in preparing the ſoil, ſo that the roots may find the leaſt reſiſtance in ſpreading, and alſo as much nouriſhment ready prepared for being abſorbed by the roots as the plants want to become vigorous, and no more; as it is well known that too much manure, as well as too little, will prevent the plants from thriving. By want of manure, the plant may, he thinks, be conſidered as ſtarved, and by too much, as choaked with food. This may perhaps be conſidered, it is conceived, as ſomewhat analogous to a chicken which will lay no eggs, or very few, by feeding it too little, or too much; and it may be with plants, perhaps as it is with animals, that too much food may be hurtful to both.

But, if carbon or coal be really the genuine food of plants, it ſeems to him doubtful whether the brown mud remaining after an infuſion of dung is evaporated, be real coal, before it has undergone an ignition. It ought rather, it is thought, to be called an extract, and may again be diffuſed through water, or diſſolved, as it was before the evaporation; but when it is burned into real coal, it is become almoſt totally inſoluble in water, as all charcoal is generally well known to be. Charcoal is not only inſoluble, but almoſt unalterable, incorruptible, poſſeſſing, only when newly ignited, an antiſeptic power, which it recovers again by a new ignition; and he cannot help ſtill doubting whether real coal, reduced even to impalpable powder, poſſeſſes any manifeſt quality by which it deſerves to be arranged among manures. The juſtly celebrated Mr. Arthur Young, having put this powder to the trial, found it had no beneficial effect at all on vegetation. Though there is no doubt but that vegetables draw in by their roots a good deal of food, yet he thinks the principal buſineſs of feeding is carried on by the leaves in the atmoſphere. Beſides the fact of M. Du Hamel deſcribed above, there are ſeveral other conſiderations which ſeem to give ſtrength to this aſſertion. Many European trees, when ſtripped at once of all their leaves, will die. (Trees in very hot climates ſuffer the loſs of their leaves by the ſcorching ſun for a time in dry weather, without periſhing.) Doctor Ingenhouſz was preſent at the following fact: the ſulphurous ſmoke from burning a few pounds of antimony mixed with nitre was accidentally driven by the wind upon a very thriving large pear-tree, full of pears half ripe; next day he found all the leaves and pears fallen off, and the tree irrecoverably dead. A plant placed under a bell, with its root in a phial full of water, will, he ſays, die when the bell is exhauſted by an air pump: it will equally periſh, if, inſtead of reſpirable air, it be immerſed in any air unfit for breathing animals. If the roots were the chief organs of feeding plants, their life might, he ſuppoſes, be ſupported in any of thoſe airs, principally ſuch as poſſeſs no acrimonious ingredient, ſuch as pure azote; but pure azote will kill a living plant, and prevent ſeeds from vegetation. Reſpirable air, moderately warm, is alone ſufficient to make a plant vegetate, without any light. He found even that ſeeds are hurt by a ſtrong light, grow ſlowly, and are often killed before the two lobes are become leaves, and their plumula and root are formed; and that, if they ſurvive the action of light, they remain commonly but weak or deformed plants. This ſhews, it is ſuppoſed, that in agriculture almoſt all ſeeds not covered will periſh, when the ſun ſhines upon them at the time of their beginning to ſwell or vegetate. His experiments have, he thinks, proved ſufficiently that ſuch ſeeds or embryo plants periſh by the light only, (which is inſupportable to all very young plants, as well as plants weakened and ſickened by tranſplantation,) and not by the heat of the ſun, or by want of moiſture. When a plant is reared up in the dark, either under the ground, or in a dark or ſhaded open place, to a certain degree of ſtrength, light becomes more and more beneficial to it: not however for its advancing in ſize, but for acquiring ſtrength, getting a lively green colour, and for its becoming fit for propagating its ſpecies, which propagation will not ſucceed without ſufficient ſun-ſhine, or at leaſt day-light, and a due degree of heat; that is to ſay, the heat of the air, and by no means the heat of the ſoil; which laſt, though very beneficial to ſome plants, is rather hurtful to ſeveral: and indeed the ground being kept moiſt by watering, is always kept cool by the continual evaporation, and yet plants in general thrive very well in moiſt ground, though always kept cool. Trees in a foreſt ſpread their principal roots to ſuch a depth as the heat of the atmoſphere can never reach; their roots are, winter and ſummer, in an uniform temperature of 50—52 degrees of Fahrenheit's thermometer. This ſhews, it is conceived, that the vegetation of trees, as is that of almoſt all plants, being ſtopped, or nearly ſo, during the winter, is revived by the heat of the atmoſphere alone, without any regard to the heat of the ſoil, which is ſcarcely ſubject to any alteration, but at the ſurface. The heat of the atmoſphere alone, it is thought, ſets the juices of trees into motion, which motion ſets, by propagation alſo, the juices of the roots into the ſame motion: thus the juices drawn from the roots upwards, empty the filaments and ſuckers, which by this motion upwards naturally become powerfully abſorbent, without any degree of heat being more neceſſary for this abſorption or attraction than is required for the ſuction of an ordinary pump. Boyle or Hales, (if he recollects well,) applying a glaſs tube to the trunk of a vine cut off in the ſpring, collected a very great quantity of juice pumped up by the roots; which motion of the fluids in vegetables depends greatly upon their irritability, according to M. Van Marum; which ſeems to be the more probable, as an electrical exploſion, directed through a plant, ſuch as euphorbia, ſtops immediately all motion in its juices by extinguiſhing the irritability. The roots thus abſorbing the moiſture preſented to their ſuckers, take in of courſe all ſalts, earth, metallic ſubſtances, &c. that can be diſſolved in water, or in the ſaline matter to be found in almoſt all waters. This ſolvent is found to be, for the moſt part, fixed air. Though we find ſome of theſe ſalts, with all their characteriſtic qualities, in ſome plants growing in a ſoil impregnated with them, as are many plants growing near the ſea-ſhore which are full of ſea ſalt; yet it is not leſs true, that moſt part of the ingredients imbibed by the roots, as well as by the leaves, trunks, and branches, undergo almoſt a total change in the organs of the plants, even ſo far as to produce in one plant a wholeſome food, and in another, its next neighbour, a true poiſon. But as he has proved before, that the atmoſphere alone can furniſh ſome plants all that is wanting for all their functions, we ought not to look too anxiouſly among rubbiſh or dung, for the true and natural food of vegetables, though in thoſe ſubſtances a greater quantity of this food is at hand, ready prepared, and partly imbibed in the form of carbonic acid, mucilage,

mucilage, oily and ſaline matter, by which the plant is enabled to provide food for throwing out and nouriſhing more branches, flowers, and fruits. He thinks it difficult to conceive how a large tree finds, during centuries, nouriſhment on the ſame ſpot, on the ſuppoſition of M. Haſſenfratz, that its principal food is coal: and that this coal is not derived from the decompoſition of the carbonic acid (of which coal conſtitutes nearly one-third, according to M. Lavoiſier $\frac{28}{100}$). That gentleman admits doctor Ingenhouſz's diſcovery as well founded, that plants produce carbonic acid in the dark; and that roots, being always deprived of day-light, are of courſe inceſſantly occupied with this buſineſs. There exiſts every where in the ſoil common air; and common air alone is, the doctor ſays, ſufficient to furniſh, as he has proved before, carbonic acid even without plants. Thus there is no difficulty in tracing the ſource of this coal, and of conceiving how the large trees find, during centuries, that immenſe quantity of food it requires for its maintenance, growth, and abundant production of fruit or ſeed, all which is certainly derived in part from the ſoil; but he ſtill believes chiefly from the atmoſphere, by means of the leaves abſorbing and decompoſing the air in contact with them.

It is ſtated, that the tranſmutation of common air into different ſolid bodies, ſuch as plants, is a very ancient doctrine. Pythagoras and Epicurus took it, the writer ſays, for an undoubted fact; and Lucretius, who has adorned his poem "De Rerum Natura" with this doctrine, aſſerts that air changes continually into different other ſubſtances, and that theſe are again decompoſed into air, which afterward returns again into the compoſition of the different bodies; and that if this inceſſant rotation did not exiſt, every thing in this world would have been changed into air, which, of courſe, would have been at laſt the only ſubſtance exiſting. Anaximenes alſo aſſerted that all bodies are made of air, or formed of aerial matters.

It is ſuggeſted that in a preceding page the doctor hinted at a new theory of a curious fact, *viz.* that plants accelerate their growth in the dark, and advance the leaſt in the middle of the day (which is an obſervation of M. Gardini). Though this theory may perhaps be erroneous, yet, as it is ſupported on a real fact, he aſſerts further that plants changing in the dark more reſpirable air into carbonic acid than they can digeſt, they throw out a large quantity of it, and thus render the air in contact with them leſs reſpirable; and that in the day they abſorb, with the atmoſpheric air ſo much matter of heat and light, or caloric furniſhed by the ſun, that they cannot digeſt it all, and therefore throw it out as ſuperfluous, combined with the oxygen which has thus acquired the nature of vital air; which vital air, though not yet obtained by plants in its greateſt purity, is however in itſelf full as pure as that which we obtain from the beſt manganeſe, or any other ingredient. In a letter to ſir John Sinclair, in 1794, he quoted as a proof of carbonic acid being the principal food of plants, the fact he diſcovered, that the wonderful apparatus which a plant produces when it is occupied with the propagation of its ſpecies, *viz.* the flower, is inceſſantly producing carbonic acid. By this obſervation we may, it is thought, be led to the knowledge of the true natural food of vegetables; and it may be ſaid as a further illuſtration, that if we were deſirous to know what is the natural food of ſome particular animals, one of the ſureſt methods to find it out, would be to obſerve what kind of nouriſhment the parents bear to their young. Thus we ſhould find that a pigeon is beſt fed by grains, and a ſwallow by inſects. By a ſimilar concluſion, it is inferred that the true, or principal aliment of plants is reſpirable air decompoſed. By examining the air thus decompoſed, he found it conſiſted of two ſubſtances, *viz.* of fixed air or carbonic acid gas, and phlogiſticated air, or azote; but as carbonic acid contains two diſtinct ſubſtances, *viz.* coal or carbon, and oxygen, it may be queſtioned which ingredient of the two is the real food we look for. M. Haſſenfratz thinks it is principally coal: though his opinion is that the plant does not derive the coal from the carbonic acid, but from the ſoil or dung. The doctor is, however, much inclined to think that both theſe ſubſtances ſerve as food: and he is moreover inclined to believe that the azote alſo enters the plant, and has alſo ſome ſhare in feeding it. One of his reaſons for thinking ſo is, that plants abſorb continually the whole of the atmoſpheric air, and that in ſeparating this fluid by decompoſition into its conſtituent parts, they throw out that part of it which they cannot fully digeſt at the time it is produced, *viz.* at night, the azote and the carbonic acid diſengaged one from another, or only mechanically, not chemically, as formerly they were mixed, and in the ſun-ſhine the oxygen almoſt alone, the carbon and the azote remaining within the plant at that time. Though he thinks it probable that the azote enters, in ſome way or other, into the compoſition of plants, yet he ſuppoſes it is not abſolutely neceſſary for a plant, as a plant thrives admirably well without it, *viz.* in pure oxygen. It is true, however, that plants alſo die in pure carbonic acid; but in this caſe the plant may be perhaps conſidered as if it were choaked with it. He, however, acknowledges very readily, that the juſt mentioned theory has not all the clearneſs he could wiſh to give it. But the facts quoted to ſupport it, though contradicted during twelve years, are now, it is aſſerted, admitted, even by thoſe who have been the chief oppoſers of the doctrine.

The writings of the late Dr. Darwin have furniſhed a variety of uſeful and intereſting facts and obſervations on the nature of the food of plants, and the general economy of vegetables. In the analogy which he has drawn between the manner in which animals and vegetables are nouriſhed and ſupported, there is much that renders the theory of the food of plants more clear and intelligible. It is ſtated, that the various ſubſtances which conſtitute animal bodies, or which are found in the cavities of them, are compoſed from ſimpler elements by the proceſs of digeſtion, and ſanguification, and ſecretion; for it is well known that even milk, which ſo much reſembles the chyle of animals, is not abſorbed by the lacteals, without its being previouſly coagulated, and again diſſolved in the ſtomach by the power of digeſtion. Hence it happens, that the chyle of all animals, and from every kind of food which they take into their ſtomachs, is very ſimilar; and, like milk, conſiſts of water, ſugar, mucilage, and oil; the laſt of which, not being ſoluble in water, but only miſcible with it, gives its opaque white colour. But that though the chyle from different kinds of aliment is ſo ſimilar, that all the various conſtituent parts of animal bodies are ultimately produced from the chyle by ſanguification and ſecretion; yet it happens that ſome kinds of aliment poſſeſs a greater quantity of thoſe particles, which make chyle, than other kinds of aliment; ſuch materials, for inſtance, as already contain much ſugar, mucilage, and oil, which exiſt in chyle; there may, it is ſuppoſed, be other materials, which are inviſible from their perfect ſolution in water, either alone, or when converted into acids by the addition of oxygen; as carbon, phoſphorus, calcareous earth, marine and ammoniacal ſalts; though it is more probable that the two laſt are formed and ſecreted by animal proceſſes, as well as ſe-

lected

lected by the abſorbent roots of vegetables, as they are more compounded bodies than the former kinds.

And it is aſſerted that ſimilar to this chyle of animals is the ſap-juice, which is abſorbed from the earth by the roots of plants, conſtitutes their nouriſhment, and conſiſts of water, ſugar, and mucilage, with other tranſparent ſolutions, as of carbon, phoſphorus, and calcareous earth. But though it has been proved by the experiments of ſome philoſophers, that vegetables can extract or compoſe all theſe ſubſtances from air and water alone, yet ſome materials contribute more to the production of this vegetable chyle or ſap-juice than others, ſuch as the recrements of dead vegetable and animal ſubſtances in general.

The doctor therefore obſerves, that if any one ſhould aſk what is the food of animals? he ſhould anſwer, that in the moſt early ſtate of animal life the embryo lives on a mucilaginous fluid with which it is ſurrounded, whether in the egg or womb: that in its infant ſtate the young animal is ſuſtained by milk, which its ſtomach converts into chyle or nouriſhment: and that in their adult ſtate, animals are ſuſtained by other vegetable or animal ſubſtances taken into their ſtomachs, which are there converted into chyle, partly by a chemical and partly by an animal proceſs; as by a mixture of gaſtric juice with water and heat, ſome of theſe recrements of organic nature are decompoſed, either into their ſimpler component parts, or ſometimes even into their elements; while other parts of them are only rendered ſoluble or miſcible with water, and are then drunk up by the abſorbents of the ſtomach and inteſtines. In this proceſs of digeſtion much ſugar is produced, which is probably immediately ſelected and drunk up by the numerous mouths of the lacteals or lymphatics, to which it is preſented by the vermicular or periſtaltic motions of the ſtomach and inteſtines. And as this ready ſelection and abſorption of the ſugar, as ſoon as it is formed, prevents it from paſſing into the vinous or acetous fermentation; it is probable, that from the want of ſuch a means of ſeparating ſaccharine matter, as ſoon as it is formed, chemiſtry has not yet been able to produce ſugar from its elements without the aſſiſtance of animal digeſtion, or vegetable germination, as in the proceſs of malting.

It is further remarked, that in this proceſs of digeſtion, it is believed a great part of the water, ſugar, mucilage, and oil, which exiſt in vegetable and animal recrements, are not decompoſed into their elements, but abſorbed by being ſoluble or miſcible with water; the carbon, the phoſphorus, and the hydrogen, are alſo, it is ſuppoſed, diſſolved in the other fluids by means of oxygen, and form a part of the chyle, without their being converted into gaſes; for, when this happens to any exceſs, in reſpect to carbon, it eſcapes from the ſtomach in eructations; and the ſame occurs to the inflammable air or hydrogen, if a part of the water becomes decompoſed in the inteſtines; which, if it be not abſorbed by its ſolution in other fluids, but acquires a gaſeous ſtate, is liable to eſcape below; though both theſe gaſes ſeem occaſionally to revert to a fluid ſtate, from their aerial one in the ſtomach or inteſtines, and to be then capable of being abſorbed by the lacteals or lymphatics of the ſyſtem.

It is aſked what then is the food of vegetables? The embryon plant in the ſeed or fruit is ſurrounded with ſaccharine, mucilaginous, and oily materials, like the animal fœtus in the egg or uterus, which it abſorbs and converts into nouriſhment; while the embryon buds of deciduous trees, which is another infantine ſtate of vegetables, are ſupplied with a ſaccharine and mucilaginous juice, prepared for them at the time of their production, and depoſited in the roots or ſap-wood of their parent-trees, as in the vine, maple, and birch; which ſaccharine matter is ſoluble and miſcible with the water of the ſurrounding earth in the ſubſequent ſpring, and is forcibly abſorbed by their root-veſſels, and expands their naſcent foliage or leaves.

It is therefore concluded, that in their infantine ſtate, there is a wonderful analogy between plants and animals; and it is particularly curious to obſerve in the proceſs of converting barley into malt, by the germination of the ſeed, that the meal of the barley is, in part, converted into ſugar by the digeſtion of the young plant, exactly as in the animal ſtomach. The wonderful effect of vegetable digeſtion in producing ſugar may be deduced from the great product of the ſugar-cane, and of the maple-tree in America; and the wonderful effect of animal digeſtion in producing ſugar, appears in patients who labour under diabetic affections.

It is now proper to come to the conſideration of the food of adult plants; and in this conſiſts the great and eſſential difference between the nutritive proceſſes of animals and vegetables. The former are poſſeſſed of a ſtomach, by which they can, in a few hours, decompoſe the tender parts of vegetable and animal ſubſtances by a chemical proceſs within themſelves, conducted in the heat of ninety-eight degrees, with a due quantity of water, and a perpetual agitation of the ingredients; which both mixes them and applies them to the mouths of the abſorbent veſſels which ſurround them. Whereas a vegetable being, having no ſtomach, is neceſſitated to wait for the ſpontaneous decompoſition of animal or vegetable recrements; which is indeed continually going on in thoſe ſoils and climates, and in thoſe ſeaſons of the year which are moſt friendly to vegetation; but is in other ſituations, and in other ſeaſons, a ſlow proceſs in a degree of heat as low as 40° of Fahrenheit, (in which the rein-deer moſs, *moſchus rangiferinus*, vegetates beneath the ſnow in Siberia,) and often without an adapted quantity of water to give a due fluidity, or any mechanical locomotion to preſent them to the abſorbent mouths of their roots: or in ſtill worſe ſituations, adult vegetables are neceſſitated ſtill more ſlowly to acquire or produce their nutritive juices from the ſimpler elements of air and water, with perhaps the ſolutions of carbonic acid and calcareous earth, and perhaps of ſome other matters, with which one or more of them abound, or are ſaturated. See AIR, WATER, CARBONIC *Acid Gas*, and CALCAREOUS *Earth*.

It is however remarked, that M. Haſſenfratz found that the vegetation of thoſe plants was imperfect which had not been ſuffered to grow in contact with the earth; as they never arrived at ſuch maturity as to produce fruit, and were found, on analyſis, to contain a leſs portion of carbon than other plants of the ſame kind. The experiments were tried on hyacinths, kidney-beans, and creſſes. Hence the doctor thinks the other great difference which exiſts between theſe two extenſive kingdoms of nature is, that the larger and warmer blooded animals certainly, and it is ſuppoſed all the tribes of inſects, and of colder-blooded creatures alſo, cannot exiſt long on air and water alone, except in their ſtate of hibernal torpor. The neareſt approach to this is, however, it is thought, ſeen in ſome fevers, where water alone has been taken for a week or two, and yet the patient has recovered: and there is a well atteſted account of a numerous caravan, which having loſt their route or their proviſions, are affirmed to have lived ſome weeks on gum-arabic and water, without any other ſubſtance.

But vegetables, on the contrary, as ſuggeſted above, can, it is conceived, exiſt, though in a feebler ſtate, on water and air alone, with the carbonic acid, and perhaps other inviſible ſolvents,

ſolvents, which theſe elements unavoidably contain. This is ſuppoſed to be owing to the low degree of heat which they produce internally, and to the ſlow circulation of their blood, or ſap-juice; from both which circumſtances leſs nutriment is expended, as is the caſe by animals which ſleep during the winter ſeaſon in their habitations, or other places.

It is therefore ſuggeſted, that, for the purpoſe of ſupplying adult vegetables with nouriſhment, it ſhould firſt be conſidered what kinds of matter are moſt prevalent or moſt neceſſary in their compoſition. Secondly, what of theſe ſubſtances they can abſorb without previous decompoſition. And laſtly, how to expedite the decompoſition of vegetable and animal ſubſtances on or in the ſoil, like the digeſtive proceſſes in the ſtomachs of animals; we may, in this way, it is ſuppoſed, become acquainted with the ſources and the management of manures as the food of plants. And it is not improbable but that their uſes and applications on lands may be regulated and conducted with greater certainty and ſucceſs. See MANURE, and VEGETATION.

FOOL, according to Mr. Locke, is one who makes falſe concluſions from right principles; by which he is diſtinguiſhed from a madman. See FOLLY.

Dr. Willis relates, that, upon diſſecting a fool, the principal differences found between him and a man of ſenſe, were, that the brain was ſmaller; and that the cervical plexus, formed of the intercoſtal nerve, whereby the correſpondence between the brain and heart is effected, was leſs, and ſent forth fewer branches to the heart, &c. Nervor. Deſcript. & Uſ. cap. 26.

FOOL'S PARSLEY, in *Botany*. See ÆTHUSA.

FOOL'S *Stones*. See ORCHIS.

FOOLADO, in *Geography*, a kingdom of Africa, on the banks of the Senegal river, between the 5th and 7th degrees of W. longitude, and the 12th and 14th of N. latitude. This is ſaid to be the original country of the Foulahs, but they poſſeſs many other kingdoms at a great diſtance from each other. See FOULAHS.

FOOLCHOKY, a town of Bengal; 15 miles N.E. of Maulda.

FOOLICONDA, a town of Africa, in Yani, on the N. ſide of the Gambia; 60 miles N.W. of Piſania. N. lat. 14° 3′. W. long. 14° 25′.

FOOLOMANICA, a town of Africa, in Foolado. N. lat. 13° 10′. W. long. 6° 2′.

FOOLOOTA, one of the ſmaller Friendly iſlands; 24 miles N. of Annamooka.

FOOLPARAS, a town of Hindooſtan, in Bahar. N. lat. 26° 19′. E. long. 86° 41′.

FOOLPOUR, a town of Hindooſtan; 16 miles N.W. of Benares.

FOOSHT, a ſmall iſland of the Red ſea, of an irregular form, about five miles from N. to S. and about nine in circumference. On the ſouth it is low and ſandy, and on the north is a black hill or cape that may be ſeen at the diſtance of four leagues. It has two watering-places; one on the E. of the iſland, the other on the W. When the water is firſt taken up, it is muddy, and appears as black as ink: but when it has ſettled two or three days, it becomes excellent. The wells are taken care of by a Marabout or ſaint, to whom this office belongs. This iſland is covered with a kind of bent graſs, which, for want of rain, and by the conſtant feeding of the few goats that are kept here, is prevented from growing to any height. The end of the iſland ſounds very hollow underneath, like Solfaterra near Naples; and as quantities of pumice-ſtones were found here, there is reaſon for preſuming that the black hill was once a volcano. It abounds in good fiſh; ſome of which, though not the beſt for food, exhibited very beautiful colours. The inhabitants are poor fiſhermen of a blackiſh colour, and go naked, except that they wear a rag about their waiſt. Their faces are neither ſtained nor painted. The fiſh they catch is carried to Loheia, and exchanged for dora and Indian corn, as they have no bread but what they procure in this way. They have here a flat fiſh with a long tail, the ſkin of which is a ſpecies of ſhagreen, with which are made the handles of knives and ſwords. Pearls too are found here; but they are neither large nor of a good water. The iſland abounds with beautiful ſhell-fiſh, and ſponges of the common kind are collected along the coaſt. The town conſiſts of about 30 huts, built with faggots of bent graſs or ſpartum, and theſe are ſupported within by a few ſticks, and thatched with the graſs of which they are built. At the diſtance of 4 miles, E.N.E. is Baccalun, an iſland, low, long, and as broad as Fooſht, inhabited by fiſhermen; without water in ſummer, which is brought from Fooſht; but in winter rain water is preſerved in ciſterns. Theſe were built in ancient times, when this was a place of importance for the fiſhing of pearls, and they are at this day in perfect repair. Fooſht is the moſt convenient watering-place for ſhips bound up the channel from Jibbel-Teir; and the weſtern watering place is moſt eligible. N. lat. 15° 59′ 43″. E. long. 42° 27′. Bruce's Travels, vol. i.

FOOT, a part of the body of moſt animals, whereon they ſtand, walk, &c.

Animals are diſtinguiſhed, with reſpect to the number of feet, into bipedes, *q. d. two-footed*; ſuch are men and birds; quadrupeds, *q. d. four-footed*; ſuch are moſt land animals: and multipedes, *q. d. many-footed*; as inſects. The reptile kind, as ſerpents, &c. have no feet.

Galen has ſeveral good obſervations on the wiſe adjuſtment of the number of feet in men and other animals, in his book De Uſu Part. lib. iii.

The fore-feet of the mole are admirably formed to dig, and ſcratch up the earth, and make way for its head, &c.; in water-fowls, the legs and feet are excellently adapted to their reſpective occaſions, and manners of living; in ſuch as are to wade in rivers, the legs are long and bare of feathers a good way above the knee; their toes alſo are broad; and in ſuch as bear the name of *mudſuckers*, two of the toes are ſomewhat alated, that they may not eaſily ſink in walking upon boggy places.

Others, which are to ſwim, are whole-footed; *i. e.* have their toes webbed together: as in the gooſe, duck, &c. and it is pretty enough to obſerve, how artfully theſe will gather up their toes and feet, when they withdraw their legs, or go to take their ſtroke in ſwimming; and again expand, or open, the whole foot, when they preſs upon, or drive themſelves forward in the water.

FOOT, in *Anatomy*. See EXTREMITIES.

FOOT, *Bathing of*. See PEDILUVIUM.

FOOT, *Bleeding in the*. See BLEEDING.

FOOT, *Diſtortion of*. *Club-foot* is the name given to ſuch deformity and diſtortion of the foot as prove prejudicial to the functions of the part.

Children are ſometimes born with their feet thus diſtorted, and ſometimes this diſagreeable ſpecies of deformity comes on after birth, being occaſioned by a bad habit, which ſome nurſes have of making children ſtand and attempt to walk at too early a period of life.

In certain ſubjects, we find the legs themſelves diſtorted; in ſome, the knees are deformed, while in others, the fault lies in the tarſus and ankle-joint, in which caſe, the feet are twiſted either inward or outward.

The

The Latins uſed to confer the epithet *vari* on patients afflicted with a preternatural inclination of the feet inward, and the expreſſion *valgi* was applied to ſuch perſons as had their feet turned too much outward.

When the foot is diſtorted inwards, which is moſt common, the ſole aſſumes more or leſs a perpendicular poſition, and is occaſionally turned quite backward, the patient being compelled to walk on the external edge of the foot.

The deformity ſometimes affects only one foot, ſometimes both. The following external appearances are obſervable in the mis-ſhapen part. The foot is bent from before backward, ſo that the inſtep ſeems very much arched, and the ſole of courſe conſiderably excavated in the tranſverſe direction. In ſome ſubjects the metatarſal bones incline towards each other, whereby a longitudinal hollow is alſo occaſioned in the ſole of the foot. The great toe is, at the ſame time, bent inward towards the os calcis, while this latter is alſo approximated to the former part. Hence it is obvious, that the internal edge of the ſole of the foot muſt be extremely concave, and the external one particularly convex.

As the patient can only walk upon the outer edge of the foot, the ſurface of the ſole is ſoft and ſmooth; but the projecting external part of the foot (that is to ſay, the ſkin covering the metatarſal bone of the little toe, and the os cuboides) is much thickened and indurated. On compariſon with a ſound foot, the tibia ſeems to incline obliquely from behind forward in its deſcent to the aſtragalus; the heel is leſs prominent behind; and the muſcles of the calf are ſhortened.

Little, or nothing, of the internal malleolus can be felt, while the external one forms an extraordinary projection. The ſkin of the inner ankle is alſo conſiderably on the ſtretch.

The leg and thigh, compared with the reſt of the limbs, are always in an emaciated ſtate. In new-born children this circumſtance is not obſervable. The knee is turned outward as well as the whole thigh, while the ham is rolled inward.

The bones and muſcles are ſtill more remarkably altered. On examination, Camper found the neck of the aſtragalus twiſted, the fore part of the foot being drawn inward by the action of the tibialis anticus and poſticus muſcles. The peronei muſcles conſequently loſe their ſtrength, and no longer retain the power of drawing the foot outward. The aſtragalus conſequently becomes more and more diſplaced, and puſhed in the external direction. The os calcis itſelf becomes approximated to the bones of the tarſus by the action of the abductor and flexor brevis pollicis pedis. The heel is conſiderably retracted, in conſequence of the tibialis anticus and other muſcles, from their altered condition, having loſt all effectual power of counteracting the muſcles of the calf.

Brückner, a German practitioner, has referred the original defect to the os naviculare; but without having made any examinations by diſſection. This bone is ſaid to be forced more inward, and to be ſo changed in poſition, that its lower ſurface inclines obliquely inward, and the knob on its inſide obliquely upward. The os cuboides is turned obliquely outward, and, when diſplaced very conſiderably, it ſlips ſomewhat away from the anterior end of the os calcis, and from the os cuneiforme externum.

The reſt of the bones muſt all of neceſſity ſuffer, more or leſs, from the foregoing deviations from nature, and the os calcis, in particular, becomes conſiderably leſs prominent backward.

The following account is given by Cloſſius of the examination of two club-feet.

In the left foot, which was only ſlightly affected, nothing in the leaſt unnatural was obſerved betwixt the tibia and aſtragalus. The malleolus internus was of a proper length, and the os naviculare was in every reſpect naturally connected with the aſtragalus, and firſt cuneiform bone. It was only remarked that the foot, in conſequence of the great convexity of the os naviculare, had too abrupt a ſlope at its outer edge, which was inclined towards the ſole; that the third cuneiform bone was ſomewhat ſeparated from the os naviculare, and the os cuboides a little removed inward at its connection with the os calcis. From theſe circumſtances, it was inferred, that the tibialis poſticus muſcle had acted ſo powerfully on the third cuneiform and the cuboid bone as to have brought towards the ſole the outer edge of the foot, nearer to the internal margin of the ſame.

The moſt conſiderable deformity was in the right foot.

The narrow part of the aſtragalus was twiſted inward and downward, and on the inſide it and the head of the bone were compreſſed together. The ſurface, articulated with the tibia, was puſhed ſo much obliquely inward, that a conſiderable portion of it in front was not at all oppoſed to the tibia, while the back part of the latter had a new articular ſurface formed on it. The ſide of the articular ſurface of the aſtragalus, and the malleolus externus connected with it, were both thrown more forward, out of their natural ſituation. The part of the aſtragalus to which the malleolus internus is joined, was with ſome of this latter proceſs abſorbed.

The tibia extended very obliquely from above downward, and from behind forward to the os calcis, or elſe the protuberance of the latter was drawn upward, ſo as to appear ſhortened.

The whole of the aſtragalus being diſtorted inward, it follows, that its head of courſe projected externally, and formed a prominence on the back of the foot.

The os naviculare was rightly connected with the three cuneiform bones, and was not in the leaſt mis-ſhapen.

The back of the foot was alſo remarkably convex, and the os calcis conſiderably bent forward towards the great toe. As the inſide of the head of the aſtragalus was abſorbed, and its neck diſplaced inward, the os naviculare was in cloſe contact with the remains of the malleolus internus. Neither the os naviculare, nor the os cuboides, was at all narrower than the correſponding bone in the oppoſite limb, ſo that the great toe did not incline preternaturally towards the heel, though this may be the caſe when the deformity is very conſiderable.

Cloſſius is of opinion that the diſtortion originated as follows: the tibialis poſticus muſcle had approximated the outer edge of the foot to the inner one, and conſequently had occaſioned a longitudinal excavation in the ſole. The fibres of the tendon of the ſame muſcle, which ran in a ſtraight direction to be implanted into the cuboid, third cuneiform, and navicular bones, had acquired the power of ſtrongly turning the foot inward, and forcibly extending it. Hence, the ſole was rendered very hollow tranſverſely, and the inſtep particularly convex; hence the end of the foot pointed downward conſiderably, while the os calcis was drawn up very high; and hence aroſe the diſtortion of the aſtragalus, and the palpable abſorption of certain portions of this bone.

When the head and neck of the aſtragalus are diminiſhed, the abductor pollicis pedis can act with great effect on the

projecting lever of the os calcis, ſo as to diſtort this bone inward and upward, and bring the great toe nearer to it.

The cauſe of the diſtortion is not always to be imputed, as ſome have imagined, to a partial luxation of the ankle-joint; but to a change in the form of the bones, more eſpecially of the aſtragalus.

In conſequence of the diſtortion of the foot, the muſcles which are ſituated in the ſole, and run from behind forward, become conſiderably ſhortened, ſo that the toes bend on every attempt to put the foot in a ſtraight poſition. That the peronei muſcles muſt be conſiderably on the ſtretch muſt be manifeſt to every body.

Camper thought the reaſon of the leg's being emaciated quite inexplicable, as there is no defect in the functions of the digeſtive organs, and no preſſure operating on the part.

Cloſſius ſuggeſts, as an explanation of the cauſe of the preceding change, the unnatural poſition, the tenſion, and the inactive ſtate of the muſcles; for club footed perſons neither move their ankle, nor their knee-joints, but bring their feet forward in a circular manner, with ſtiff knees and a limping gait. The feet are not approximated in walking, and the thigh and knee become conſiderably turned outward. Alſo, ſince ſuch perſons tread upon the outer edge of the foot, the peronei muſcles muſt be continually more and more weakened, and the deformity increaſed.

Camper has imputed the occaſional cauſe of the diſtortion to want of room in the uterus. However, other authors maintain, that this cauſe is by no means eſtabliſhed, ſince, during the five firſt months of geſtation, the child can move very freely in the womb, and as there is even at a later period no particular deficiency of ſpace. Other authors have conceived that a more likely cauſe is the foot's being propelled by ſome incident or another into a preternatural poſition in the womb, and remaining in ſuch condition.

It is curious however (if what ſome writers allege be true), that the club-foot ſhould occaſionally prevail in particular families, and ſeem to be an hereditary affection.

The deformity may alſo come on after birth, when children, either from inclination, or in conſequence of ulcers on the ſole, accuſtom themſelves to tread upon the outer edge of the foot.

The cure is the more eaſy of accompliſhment, the younger the child is, and hence it is a rule to begin the treatment at an early period. The affliction, however, has been removed in children thirteen years of age.

The firſt indication in the treatment is to make the contracted tendons, faſciæ, and muſcles ſupple again. Surgical writers, with this view, recommend the employment of warm bathing, which is to be repeated every day. They alſo adviſe the foot to be rubbed with oleaginous applications, or bathed in warm oil, and rubbed with the ſame. The frictions are to be made as far upward as the ham, and the limb is likewiſe to be bathed to this extent.

After keeping the foot immerſed for a certain time, an endeavour is to be made to ſtraighten it, and bring it more into a natural poſition. This trial is to be repeated ſeveral times in the courſe of the day, and particular care muſt be taken to depreſs the heel.

It is to be underſtood that the attempts are to be made with great care and perſeverance, and that the child muſt be entirely prohibited from putting the affected foot to the ground.

Before having recourſe to the employment of machines for the purpoſe of keeping the foot in the deſired poſition, it is always worth while to try what ſimple bandages will effect; for machines can only be uſed on ſuch children as are ſomewhat advanced in life, and the deformity is invariably the more eaſy of removal, the fewer years the patient has attained.

Some ſurgeons adviſe the uſe of a bandage, applied all over the part, and compoſed of a fine towel or piece of muſlin. The advantage of ſuch a contrivance is, that it does not cut the limb too much. The knot is to be made on the middle of the inſtep, ſo as that the bandage may ſtrongly draw the toes outward and upward, and thus lower the heel.

Some degree of benefit may be expected from the uſe of this kind of bandage in all thoſe caſes in which the diſtortion is not too conſiderable; and the os calcis not too much bent.

When the child begins to walk, it always turns its toes inwards, and does not bend its knee; conſequently the gait is attended with a motion of the body from one ſide to the other, the child treads on the point of its foot, and the heel is drawn up.

Due care at length makes all theſe defects diſappear. The toes muſt always be kept inclined outward, and the child muſt be taught to bend its knee without elevating the heel.

At laſt, the young patient ſhould wear half-boots, the outer edge of which muſt be higher than the inner one. They are alſo to be made without heels.

With regard to machines, we ſhall only obſerve that ſome practitioners confine the foot in a natural poſture with leg-irons of different conſtructions. Some maintain the part in a right poſition, with boxes of tin, or copper, or with ſtrong leather boots. Others uſe a more complicated apparatus, which conſiſts of metal ſhoes, in which the foot is confined, and of a wheel fixed by a ratchet, for the purpoſe of keeping the toes turned outward.

The inconveniences of ſuch methods are, that when the machines do not allow room for the ankle to move, the joint becomes ſtiff, and that when there is room, a due degree of ſupport is not afforded. Mr. Sheldrake has ingeniouſly obviated theſe difficulties, by deviſing a kind of ſpring, which is the operating power, and which is ſo advantageouſly made, that when the limb is moved, the apparatus acts with increaſed force. See Cloſſius über die Krankheiten der Knochen, Tübingen, 1798. Sheldrake on the Club-foot.

FOOT, *Fracture of.* See FRACTURE.

FOOT, *Luxation of.* See LUXATION.

FOOT, in the *Manege*, is the extremity of a horſe's leg, from the coronet to the lower part of the hoof. The four feet are diſtinguiſhed by four different names; the two fore-feet are by ſome called the hands of a horſe; but that term is in diſuſe, the common expreſſion being the far fore-foot, to denote the right foot before; and the near fore-foot, the ſtirrup-foot, and the bridle hand-foot, to denote the left foot before.

Of the two hinder feet, the right is called the far hinder-foot; and when ſpears were uſed, it was called the ſpear-foot, becauſe in reſting the ſpear the ſocket of it anſwered the right hinder-foot. The left hind foot is called the near foot behind. See *Veterinary* ANATOMY.

FOOT-*derobé*. A horſe's foot has this appellation when it is worn and waſted by going without ſhoes, ſo that for want of a hoof, it is a hard matter to ſhoe him.

A horſe's foot is ſaid to be worn and waſted, called in French *uſé*, when he has but little hoof, and not enough for ſhoeing.

FOOT, *to gallop upon a good*, or put a horſe upon a good

foot, called in French *ſur le bon pied.* See *Falſe* GALLOP.

FOOT, *Fat.* A horſe is ſaid to have a fat foot, when the hoof is ſo thin and weak, that unleſs the nails be driven very ſhort, he runs the riſk of being pricked in ſhoeing. The Engliſh horſes are very ſubject to this diſorder.

FOOT-*ſoldier*, implies that claſs of military perſons who are included in the roll of privates in marching regiments, and in all corps which act on foot, in contra-diſtinction to ſuch as are mounted, and come under the deſignation of *horſe-ſoldiers*, more commonly called *cavalry*.

No recruit ought to be paſſed into any regiment of foot, whoſe ſtature ſhould be under five feet ſix inches, or whoſe form, health, and ſenſes might appear to be in any inſtance defective. In time of war, indeed, ſome little relaxation from that ſtrictneſs which ought to obtain where candidates are abundant, muſt be admitted; but ſuch ſhould be under certain circumſtances only. It is a fact that, at the termination of a war, when many regiments are diſbanded, thoſe who return to their homes are rarely able to obtain a livelihood, owing to their having been reduced greatly, in regard to their phyſical powers, by the fatigues and hardſhips attendant upon a profeſſion to which their conſtitutions were unequal, and wherein they would not have been admitted, but from the abſolute neceſſity exiſting during times of emergency; when any human being becomes acceptable! The ſervices demanded of a foot-ſoldier are ſevere indeed; eſpecially in the regiments of artillery. In that highly reſpectable corps, much circumſpection is uſed in the ſelection of recruits, as well as in their ſubſequent training; it being peremptorily neceſſary, that every individual, beſides poſſeſſing the proper ſtature, form, and conſtitution, ſhould be active and intelligent, ſince on the preſence of mind, ingenuity, and profeſſional ſkill of the artilleriſt, though of the loweſt ranks, the moſt important conſequences have often been found to depend.

The pay of a foot-ſoldier correſponds with the rank of the corps, or branch of the ſervice, in which he may ſerve. In the artillery it amounts to 1*s.* 3$\frac{1}{2}$*d.* per diem; in the foot-guards to 1*s.* 1*d.*; and in regiments of the line to 1*s.* But in addition to this, they are ſerved with bread, in a very liberal proportion, and experience many little indulgences, eſpecially in being ſupplied by publicans, &c. on whom they may be billetted, with beer and victuals at fixed rates, ſuch as occaſion their room, rather than their company, to be a deſideratum with their hoſts.

Formerly every foot-ſoldier was armed cap-a-pee; but it being ſoon perceived that one efficient implement, well handled, was far ſuperior to that variety which at leaſt encumbered, if it did not diſtract the attention of the individual bearing the motley armour, the weapons uſed by foot-ſoldiers are now confined to the muſket and bayonet; which may not improperly be conſidered as but one. The only caſe in which a ſword ſeems admiſſible is in rifle corps; wherein, from the want of an efficient bayonet, ſome ſuch defence againſt an enemy coming to cloſe quarters is abſolutely neceſſary.

FOOT, in *Mining*, ſignifies to reach the bottom of a ſtratum; thus to "foot a coal," is to ſink a ſhaft through it to its under ſtratum or floor.

FOOT *of the eye's director*, in *Perſpective*, is that point in the directing line made by a vertical plane paſſing through the eye and the centre of the picture.

FOOT *of the vertical line*, is that point in the interſecting line, made by a vertical plane paſſing through the eye and the centre of the picture.

FOOT, in the *Greek* and *Latin Poetry*, denotes a metre, or meaſure, compoſed of a certain number of long and ſhort ſyllables.

The ſpondee, iambic, trochee, and pyrrhic, are diſyllabic feet; *i. e.* they conſiſt of two ſyllables each; the dactyl, anapſtæ, moloſſus, tribrach, bacchius, antibacchius, amphibrachys, and creticus, are triſyllabic, or conſiſt of three ſyllables each; the proceleuſmaticus, choriambus, and epitrite, are quadriſyllabic, or compoſed of four ſyllables. See each under its proper head, SPONDEE, IAMBIC, &c.

There are alſo other feet, invented by grammarians, of five, ſix, or more ſyllables; but they are not worth the reciting.

Hexameter verſes conſiſt of ſix feet; pentameters, only of five.

A foot in poetry ſeems to reſemble a bar in muſic. A *trine* among the ancients was a portion of that foot or bar; as with us a bar is divided into accented and unaccented parts. "Modern muſic, ſays Mr. Harris, Diſc. on Muſ. Paint. and Poet. p 73, 1ſt edit. has many different lengths of notes in common uſe, all which may be infinitely compounded, even in any one time or meaſure. Poetry, on the other hand, has but two lengths or quantities, a long ſyllable and a ſhort, which is its half; and all the variety of verſe ariſes from ſuch feet and metres, as theſe two ſpecies of ſyllables, by being compounded, can be made to produce." What is here ſaid of verſe, is equally applicable to ancient muſic, which was ſtrictly confined to verſe: and it ſeems as if whole pages could not place the difference between the rhythm of ancient and modern muſic, in a clearer point of view. See TRINE, RHYTHM, ACCENT, and TACT. Beating time with the foot, ſee ARSIS and THESIS, and NOTATION *of Poetical Feet* in Greek and Latin verſe. The different meaſures of poetry being called *feet*, the Greeks called ὑπορχημα a kind of poetry compoſed, not only to be ſung to the ſound of flutes and citharas, but to be danced at the ſame time. The Italian term ballata, the French ballade, and the Engliſh word ballad, had formerly the ſame import; implying ſeverally a ſong, the melody of which was to regulate the time of a dance. And the different meaſures of poetry being called feet, both in ancient and modern languages, ſuggeſts an idea that dancing, if not anterior to poetry and muſic, had a very early and intimate connection with them both. The poet Simonides defined poetry an eloquent dance: and dancing, a ſilent poetry.

FOOT, *Even and odd*, par and impar. In poetry, and particularly in iambic verſes, feet are denominated *odd* and *even*, in reſpect of their ſituation in the verſe. Thus, the firſt, third, and fifth, foot of the verſe, are uneven; becauſe thoſe numbers are not capable of being divided into two equal parts.

In the ancient tragedy, the iambic verſes, which prevailed therein, only allowed uneven feet to the ſpondees; ſo that the ſecond, the fourth, and ſixth feet, were to be iambics, becauſe they were even. This regular mixture of ſpondees in the uneven feet rendered the verſe the more ſolemn and noble.

The comic poets, the better to diſguiſe their verſe, and make it more like proſe, took the contrary courſe; putting ſpondees where the tragic poets would only have allowed iambics.

FOOT is alſo a long meaſure, conſiſting of twelve inches. The foot long is divided into twelve inches, and the inch into barley-corns. Thus the Engliſh ſtandard foot (31 Edw. I.) is = 12 lineal Engliſh inches, = 36 barley-corns, = 16 digits, = 4 palms, = 3 hands, = 5$\frac{1}{3}$ nails, = 1$\frac{1}{2}$ ſpans,

ſpans, = 1.5154 Gunter's links, = .938306 pieds, or feet of France, = .3047 metres of France.

Geometricians divide the foot into ten digits, and the digit into ten lines, &c.

The French divide their foot, as we do, into twelve inches; and the inch into twelve lines. See *French* MEASURES.

The foot ſquare is the ſame meaſure, both in length and breadth, containing 144 ſquare, or ſuperficial inches, = 2.295684 ſquare links; and the glazier's foot in Scotland is = 64 ſquare Scotch inches.

The cubic, or ſolid foot, is the ſame meaſure in all the three dimenſions, containing 1728 cubic inches Engliſh = 6.128 ale gallons = 3.478309 cubic links = .0283 cubic metres or ſteres of France. See *French* MEASURES.

The foot is of different lengths in different countries. The Paris royal foot exceeds the Engliſh by nine lines and a half; the ancient Roman foot of the Capitol conſiſted of four palms, equal to eleven inches and ſeven tenths Engliſh; the Rhinland, or Leyden foot, by which the northern nations go, is to the Roman foot as 950 to 1000. The portions of the principal feet of ſeveral nations, compared with the Engliſh and French, are here ſubjoined.

The Engliſh foot being divided into one thouſand parts, or into twelve lines, the other feet will be as follow:

		Th. Pts.	F.	Inch.	Li.
London - -	Foot	1000	0	12	0

Mr. Raper, who has induſtriouſly collected a variety of authorities relating to the meaſure of the old Roman foot, determines the mean to be nearly 968 thouſandth parts of the London foot. And by an examination of the ancient Roman buildings in Deſgodetz's Edifices Antiques de Rome, Paris, 1682, he concludes, that the Roman foot before the reign of Titus exceeded 970 parts in 1000 of the London foot; and in the reigns of Severus and Dioclesian fell ſhort of 965. Phil. Tranſ. vol. li. art. 69. p. 774, &c.

The Paris foot being ſuppoſed to contain 1440 parts, the reſt will be as follow:

Paris - -	Foot		1440
Rhinland -	—		1391
Roman -	—		1320
London - -	—		1350
Swediſh - -	—		1320
Daniſh - -	—		1403
Venetian - -	—		1540⅖
Conſtantinopolitan	—		3120
Bononian - -	—		1682⅔
Straſburg - -	—		1282⅝
Norimburg -	—		1346¼
Dantzick - -	—		1721½
Hall - -	—		1320

In Scotland, this meaſure of length, though conſiſting of twelve inches, exceeds the Engliſh foot, ſo that 185 of the former is equal to 186 of the latter. Accordingly the Scotch foot = 12 Scotch inches, = $12\frac{1}{15}$ Engliſh inches, according to ſome, and $12\frac{12}{185}$ Engliſh inches according to others. The glazier's foot in Scotland = 8 Scotch inches. For a further account of the foot, ancient and modern, and its proportions in different countries, ſee MEASURE.

FOOT-*bank*, or *foot-ſtep*, in *Fortification*. See BANQUETTE.

FOOT-*pace*, in *Architecture*, is a flat ſpace in ſome ſtairs inſtead of winders, always ſituated between the ſtarting place and the landing.

When the foot-pace occupies one quarter of a revolution at the turning it is called a quarter pace: and if it occupy half a revolution, it is called a half pace.

Foot-paces are introduced in order to ſave the expence of winders, and to give reſt to the aſcendant in advancing up ſtairs.

FOOT *of the foreſt*, *pes foreſtæ*, in our *Ancient Cuſtoms*, contained 18 inches; or $1\frac{1}{2}$ of the common foot.

"Notandum eſt, quod pes foreſtæ uſitatus tempore Ric. Oyſell, in arrentatione vaſtorum, factus eſt, ſignatus et ſculptus in pariete cancellæ eccleſiæ de Edwynſtone, et in eccleſia Beatæ Mariæ de Nottingham: Et dictus pes continet in longitudine octodecim pollices, &c." Ex Regiſt. Abb. de Novo. Loco in Com. Nott.

FOOT, *Fore*. See FORE-*foot*.

FOOT-*geld* was an ancient amercement, for cutting out the balls of the feet of great dogs in the foreſt; to prevent their running after the king's deer.

FOOT-*guards*. See GUARDS.

FOOT-*hooks*, in a *Ship*. See FUTTOOKS.

FOOT, *Horary*. See *Univerſal* MEASURE.

FOOT-*buſks*, among *Gardeners*, are the ſhort heads out of which flowers grow. See CALYX.

FOOT-*irons*, in *Engineery*, are pieces of iron plate, which the navigators or canal-diggers tye on to that part of the ſole of their ſhoes which ſtrikes the top of their ſpade or grafting-tool, in digging hard ſoil. See CANAL.

FOOT

Foot *of a ſail*, denotes the lower edge or bottom.

Foot-*level*, an inſtrument which ſerves to do the office both of a level, a ſquare, and a foot rule.

The foot-level, repreſented *Plate* IV. *Surveying*, *fig.* 1. conſiſts of two branches, about an inch broad; opening and ſhutting like a two-foot rule.

Theſe branches are hollowed half way up the ſide of each to receive a kind of tongue, or thin piece of braſs, which is faſtened to one of them, by means whereof the branches may be ſhut cloſe together. The uſe of this tongue is ſuch, that when the end of it is placed in the branch it is not faſtened to, where there is a pin that holds it, the two branches will ſtand at right angles; to the head of the inſtrument is likewiſe added a ſquare piece of braſs; by means whereof it does the office of a ſquare. At the bottom of the angle of the ſaid piece of braſs is a little hole, wherein is faſtened a line with the plummet; which falling on a perpendicular line drawn on the tongue, ſhews whether any thing the inſtrument is applied to be level or not. See Level.

Foot, *lieutenant-colonel of*. See Lieutenant.

Foot-*rule*. See Rule.

Foot-*ropes*, are thoſe to which the foot of the ſail is ſewed. They are alſo the ſame with the horſes of the yards. See Horse.

Foot-*waleing* denotes the whole inſide planks or lining of a ſhip, uſed to prevent any part of the ballaſt or cargo from falling between the floor-timbers.

Foot-*halt*, in *Rural Economy*, is the name of an affection in the foot of the ſheep, which does not yet ſeem to be well underſtood. It ſhould be well cleaned from all ſorts of dirt, and kept tied up with ſome diſcutient application. See Sheep.

Foot-*paths*, the walks, paths, or other tracks which are made in fields, by walking through them when the land is under the plough, or ſhut up for the purpoſe of hay or paſture; alſo the walks on the ſides of public roads formed for foot paſſengers. In the former caſes they are not unfrequently highly inconvenient and injurious to the farmer, from the miſchief that is done in paſſing them by tearing up or beating down different ſorts of crops.

Foot-*plough*, in *Agriculture*, a name formerly much uſed to ſignify a kind of ſwing plough.

Foot-*rot*, in *Rural Economy*, an affection or diſorder in the feet of ſheep. It moſtly commences between the claws of the fore-feet, with a ſlight inflammation and ſwelling. In this way the ſheep becomes lame, and ſome moiſture oozes out between the claws, which has a highly diſguſting ſmell; and in proportion as the diſeaſe becomes more inveterate, it gets under the hoof, producing proud fleſh. It has been commonly ſuppoſed to be infectious, on account of its ſpreading with ſuch rapidity when not promptly removed. Moſt of the long woolled and Merino breeds of ſheep, are ſaid to be very ſubject to this diſeaſe; but other ſorts of ſheep are likewiſe found to frequently ſuffer from it.

In its removal, the part affected ſhould be pared and well cleaned without touching the quick, and then a cauſtic ſolution of the following kind dropped upon it, the foot being kept well wrapped up from the dirt. Two ounces of blue vitriol, the ſame quantity of roach alum, and one ounce of verdigris, with a quarter of an ounce of muriated quickſilver, ſhould be diſſolved in a quart of good diſtilled vinegar. But there are many who make uſe of butter of antimony, applying it to the part by means of an iron ſkewer, after being pared in the manner ſtated above. It is ſaid to be a very effectual remedy in this affection

It is always a proper precaution to ſeparate the ſheep that are thus affected from the reſt of the flock. And it has been ſtated that the change of the ſheep into a more ſhort dry paſture, is of great uſe in obviating the complaint. See Sheep.

Foot-*trenches*, in *Agriculture*, a term ſometimes employed to ſignify ſmall ſuperficial drains not more than a foot in width.

FOOTA, in *Geography*, a country of Africa, near the ſource of the Gambia. N. lat. 10° to 11°. W. long. 10° to 11°.

Foota Torra, a country of Africa, between the rivers Senegal and Gambia, N. of Woolly, and N.W. of Bondou.

FOOTE, Samuel, in *Biography*, a celebrated Engliſh comedian and dramatic writer, was born in the year 1717 at Truro, in Cornwall, where his father was in the commiſſion of the peace. He received his education at Worceſter college, Oxford, whence he removed to the Temple. But diſliking the dry ſtudy of the law, he turned his attention to the ſtage, and made his firſt debut in the character of Othello, in the Moor of Venice. He opened on his own account, in 1747, the little theatre in the Haymarket, with a piece written by himſelf, entitled "The Diverſions of the Morning." The next ſeaſon he ſucceeded beyond his expectations, by the favourable reception of another of his own compoſitions, "An Auction of Pictures;" in which he holds up to the mirror of ridicule many of the moſt diſtinguiſhed characters of the time. During this period, he continued to perform ſome of the principal comic characters at Covent Garden and Drury Lane theatres. Having, in a hunting party with the duke of York, the misfortune to fall from his horſe, by which he fractured his leg, and was conſtrained to ſuffer amputation; the duke ſo far ſympathized with his loſs, as to procure him a patent for life to act comedies at the Haymarket, annually from the 15th of May to the 15th of September; on which occaſion, in 1766, he conſiderably enlarged the theatre. In a piece which he brought out in 1776, he made a moſt pointed attack on the ducheſs of Kingſton's character, which made him many enemies, who cruelly retaliated upon him by charging him with an unnatural crime; and though he was honourably acquitted of the offence, yet the ſtigma on his fame made ſuch a deep impreſſion on his mind as to impair his health; and he was ſeized with a paralytic affection, which terminated fatally. Previous to that event, he had determined on quitting England, and ſpending the remainder of his days in France; but died ſuddenly at Dover, on his way thither, October 22, 1777. He appears to have had a preſentiment of his death, in which he was not diſappointed. Prior to his departure for the continent, he viewed attentively the portrait of his friend Weſton, a celebrated actor, which he kept in his cabinet, and with tears in his eyes was heard to exclaim "Poor Weſton!" and to add in the ſame tone of dejection; "in a ſhort time others ſhall ſay, poor Foote!" His remains were buried in Weſtminſter abbey. In him the nation loſt an actor of fine imagination, and a favourite of nature. As a writer, he poſſeſſed a fund of wit, and a vaſt aptitude to ſeize and improve the ridiculous; but took unwarrantable liberties in expoſing the natural failings or peculiarities of manners in living characters. So little did he attend to method in compoſition, that it is ſaid he could never form a regular plan, or wind up properly a plot. His pieces are principally farces, or farci-comedies, which from their wit and point have procured for him the title of the *Engliſh Ariſtophanes*. Of theſe, twenty with his name are publiſhed under the title of "The Comic Theatre," three vols. 12mo. out of which it has been

been obſerved that the "Young Hypocrite" is the only one wholly of his own compoſition. See Biographica Dramatica, and Cooke's Memoirs of Samuel Foote.

FOP, probably derived from the *vappa* of Horace, applied in the firſt ſatire of his firſt book to the wild and extravagant Nævius, is uſed among us to denote a perſon who cultivates a regard to adventitious ornament and beauty to exceſs.

FOPPENS, John Francis, in *Biography*, a learned Flemiſh divine, was born about the year 1689. Of his early life no particulars have been recorded. He was one of the profeſſors of theology at Louvain, obtained preferment in the church, and high reſpect from his contemporaries on account of his erudition and virtues. He was author of "Bibliotheca Belgica," in two vols. 4to. 1739. He publiſhed a new edition of Miræus's "Opera Hiſtorica et Diplomatica," with notes and tables in two volumes folio. He was likewiſe author of "Hiſtoria Epiſcopatus Antwerpienſis:" "Hiſtoria Epiſcopatus Sylvæducencis;" and "Chronologia Sacra Epiſcoporum Belgii ab anno 1561, ad annum 1764," 12mo. a work in verſe with hiſtorical notes. He died in 1761, in the ſeventy-ſecond year of his age.

FORA, in *Geography*, a river of Naples, which runs into the Adriatic. N. lat. 42° 26'. E. long. 14°.

FORABOSCO, Girolamo, in *Biography*, a painter, who practiſed the art both in hiſtory and portraiture, but principally the latter, and that with conſiderable ſucceſs. He was born at Venice about the year 1600, but the preciſe time is not known. The principal ſcene of his exertions was Venice, where many of his performances are ſtill preſerved; particularly portraits of the Doge Contarini, painted in 1655; and of the Doge Peſaro in 1659. His moſt juſt characteriſtics are natural and brilliant colouring, and freedom of execution. The period of his death is alike unknown with that of his birth.

FORADADA, in *Geography*, a ſmall iſland in the Mediterranean, near the iſland of Majorca, where the ſon of the king of Aragon formerly erected a college for the purpoſe of inſtructing ſome Franciſcan monks in the Arabic language, for converting the Moors.

FORAGE. See Forrage.

FORAMEN, in *Anatomy*, a hole. The term is employed moſtly in the ſkeleton, and is applied to the openings which penetrate a bone. It is uſed, therefore, moſt commonly in the head, as the apertures are moſt numerous there. A complete liſt of the foramina of the head is ſubjoined to the article Cranium.

Foramen *Commune anterius and poſterius*, are two openings in the brain. See Brain.

Foramen *Epiploicum*, an opening that leads into the cavity of the great omentum. See Epiploon.

Foramen *of Monro*, a name given to a ſlit-like paſſage leading from the lateral ventricle through the foramen commune anterius to the third ventricle of the brain; which Dr. Monro did not diſcover. See Brain.

Foramen *Ovale*, of the heart; a paſſage of communication in the fœtus, between the two auricles. See Heart.

Foramen, in *Natural Hiſtory*, is a term applied to the apertures obſervable in ſome ſpecies of *echini*, diſtinct from the mouth and vent: in the compreſſed or flat echini they are often large pervious holes, formed by the local coaleſcence of the oppoſite ſides of the ſhell, and are from two to ſix in number.

FORAMINULENTUS, Tractus Spiralis, in *Anatomy*, a part of the external ſurface of the cochlea, perforated by very numerous ſmall openings for tranſmitting the filaments of the auditory nerve. See Ear.

FORBACH, in *Geography*, a town of France, in the department of the Moſelle, and chief place of a canton in the diſtrict of Sarreguemines; 7 miles N.W. of it. The place contains 1,715, and the canton 9,472 inhabitants, on a territory of 212½ kiliometres, in 25 communes.

FORBES, Patrick, in *Biography*, was born in the year 1564. He was one of the Scotch nobility, under the title of lord of Corſe, and baron of O'Neil in the county of Aberdeen. He was educated partly at Aberdeen, and partly at St. Andrew's. When he was able to take an active part in the buſineſs of life, the affairs of the church of Scotland were in a ſtate of great confuſion, and he ſoon made himſelf conſpicuous by the encouragement which he held out to able and pious miniſters, and by the inſtructions which, notwithſtanding his being a layman, he perſonally delivered to the people. He was alſo well known by the conferences which he held for the converſion of the papiſts, who would hear nothing from the pulpit. Such ſervices, in behalf of the proteſtant cauſe, were not unnoticed or forgotten in times of difficulty, and he was repeatedly urged, by perſons of high rank in the church and ſtate, to engage in the work of the miniſtry. After much heſitation on his part, he was, in the forty-eighth year of his age, ordained preſbyter, and admitted miniſter of Keith, where he diſcharged the paſtoral functions with great acceptability and applauſe. In 1618, he was nominated by the king to the ſee of Aberdeen, which he accepted, though it is ſaid, with much real and unaffected reluctance. His zeal was equal to the diſcharge of the moſt important and extenſive duty, but he did not well underſtand the principles of toleration, which are alſo the principles of pure Chriſtianity. He joined his brethren in infringing on the rights of thoſe who were attached to particular ceremonies, by enjoining certain obſervances relative to the reception of the euchariſt, and other matters to which they could not conſcientiouſly conform. He was not, however, a perſecutor, and ſcorned to make uſe of vigorous meaſures to carry his point. Some time after his promotion to the biſhopric he was elected chancellor of the univerſity of Aberdeen, and under his ſuperintendance and patronage that ſeat of learning roſe to conſiderable diſtinction; he repaired and ornamented the buildings, increaſed the library of the univerſity, revived the ſeveral profeſſorſhips of divinity, canon law, and phyſic; and procured, by his influence, a new profeſſorſhip of divinity. The good biſhop lived long enough to be amply repaid for all his attention and liberality, by the number of able and worthy men who were educated there. He died in 1635, being in his ſeventy-firſt year, leaving behind him a "Commentary on the Revelations," which was printed in 1613: and a work entitled "Exercitationes de verbo Dei, et Diſſertationes de verſionibus vernaculis." In his conduct as a biſhop, he appears to have been uniformly influenced by an honeſt regard to the obligations of the character which he had aſſumed, and what he conceived to be the beſt means of promoting the intereſts of piety and virtue. If, at any time, he erred in the means of doing good, it was an error of judgment, and he is ſaid by biſhop Burnet to have "greatly allayed, and almoſt conquered, not only the diſtempered judgments, but the perverſe and turbulent humours of divers perſons in his dioceſe." He was careful in the choice of clergymen, and was anxious to make proviſion for their ſupport, and that of their ſucceſſors. He was vigilant and ſtrict in examining candidates for orders, and frequently viſited his dioceſe to enquire into the conduct of thoſe who exerciſed the important office of miniſters of religion.

religion. In his viſitations he proceeded without pomp, attended by a ſingle ſervant, that he might be more readily informed of what belonged to his care. He would frequently attend the ſermons of his clergy, in ſuch a way as to excite no ſuſpicion that he was more than a common hearer, to aſcertain their uſual ſtrain of preaching, and after ſervice he would encourage or admoniſh the miniſter, as he ſhould judge proper. Biog. Brit.

Forbes, John, ſon of the preceding, was born at Aberdeen about the year 1593, where he was chiefly educated, but he made choice of Heidelberg as the place to finiſh his ſtudies under the celebrated David Pareus. Before he returned to his native country, he viſited other German univerſities, and made himſelf maſter of the Hebrew language, and of all the departments of knowledge uſually connected with theological purſuits. His great learning excited the attention of Burnet, who ſays, that perhaps he was excelled by none of that age. At Aberdeen he was appointed to the new profeſſorſhip of divinity which his father had been the means of eſtabliſhing, and diſcharged the duties connected with the office with great reputation, till he was deprived of it by the preſbyterian party in the reign of Charles I. Being determined not to abandon the epiſcopal principles, he ſought refuge in Holland, where he wrote his "Hiſtorico-Theological Inſtitutions," which conſtituted a moſt learned and valuable work of the kind. On his return to Scotland he retired to his eſtate of Corſe, where he ſpent his time in making additions and improvements to his "Inſtitutions," which, however, he did not live to publiſh. He died in his fifty-fifth year. Beſides the work already referred to, he was author of "Irenicum Amatoribus Veritatis et Pacis in Eccleſia Scoticana," "Annotations" to a Latin tranſlation of his father's Commentary upon the Apocalypſe, "Ten books of Moral Theology," which were all collected and publiſhed in two vols. folio at Amſterdam in 1703.

Forbes, William, the firſt biſhop of Edinburgh, was born in the year 1585. He was educated at Aberdeen, the place which gave him birth; and ſo diſtinguiſhed were his abilities, that he was very ſoon appointed profeſſor of logic in the new inſtitution of Mariſchal college, and diſcharged the duties of the place with much ſucceſs and high reputation. After this he ſpent four years in the ſtudy of divinity, eccleſiaſtical hiſtory, and Hebrew, at different German univerſities. From thence he went to Leyden, where he obtained the eſteem and friendſhip of Scaliger, Grotius, Voſſius, and the other learned men of that univerſity. From Holland he paſſed to England, and was appointed Hebrew profeſſor of Oxford. His health ſoon required him to return to his native country, where he became celebrated as a preacher; and when king James, in concurrence with the deputies of the clergy, had determined that the manner of conferring academical honours ſhould be reſtored to the ancient courſe, Mr. Forbes was admitted to the degree of doctor of divinity. The exertions of public ſpeaking being more than his conſtitution could bear, he reſigned the miniſterial duties, and was nominated to the poſt of principal of Mariſchal college; and almoſt immediately afterwards he was created dean of the faculty of theology, and made rector of the univerſity. He next accepted, though not without reluctance, of an invitation to Edinburgh; but the ſentiments of the people were ſo diſcordant from thoſe which he held on ſubjects of church government and diſcipline, that his popularity and uſefulneſs ſoon declined. He accordingly reſigned his charge, and returned to Aberdeen, where the ſentiments of the clergy and people were more congenial with his own. In 1633, when Charles I. was crowned at Edinburgh, Dr. Forbes was appointed to preach before him: the monarch was ſo highly pleaſed with his ſervices, that he created a new ſee, *viz.* that of Edinburgh, in order to make Forbes a prelate. This honour, which was ill reliſhed by the people, he did not long enjoy, being cut off by a fever in 1634, in the fiftieth year of his age, and within three months of his conſecration. He ſpent his life in endeavouring to effect peace and union among Chriſtians; and, after his death, a treatiſe of his was publiſhed, entitled, "Conſiderationes modeſtæ et pacificatæ Controverſiarum de Juſtificatione, &c." According to biſhop Burnet, he was "a great and ſublime divine, who preached with ſo much zeal and ardour, that, frequently forgetting the meaſure of time, he continued his ſermons for two or three hours." Biog. Brit.

Forbes, Duncan, a celebrated lawyer, and diſtinguiſhed judge, commonly called lord Forbes, was the younger ſon of a reſpectable family at Culloden, in the ſhire of Inverneſs, born in the year 1685. His natural inclination led him to the army; but his friends diſcovering a ſuperiority of genius, adviſed him to devote his attention to the ſtudy of literature, in which he made a conſiderable progreſs. The narrow circumſtances of a ſecond brother induced him to conſult with himſelf on the moſt probable means of raiſing a fortune, and ſupporting the credit and reputation of his family. Prudence quickly pointed to the profeſſion of law; and having been admitted to the Scottiſh bar, he ſoon obtained great and merited encouragement; but where he never proſtituted that nervous and perſuaſive eloquence, for which he was notable, to ſupport an illegal or litigious cauſe. For even in the early part of life, when ſtraitened as to pecuniary circumſtances, he had laid down as one rule for the direction of his conduct, a generous contempt of money: a maxim he conceived eſſential to the formation of what he conſtantly aſpired to, an unblemiſhed character. By noble means like theſe he ſoon became eminently diſtinguiſhed, and roſe to the higheſt honours of his profeſſion. In 1717, he was appointed the king's ſolicitor-general for Scotland, and ſoon after unanimouſly elected to repreſent that country in the Britiſh ſenate; a truſt he diſcharged with ſo much honour and fidelity, as to obtain the thanks of his conſtituents, and the favour of his ſovereign; who nominated him, in the year 1725, to the dignified office of lord-advocate. As he advanced in years, his uſefulneſs increaſed; and his great capacity and unſullied reputation were the ſole reaſons aſſigned for his exaltation to the preſident's chair, which he filled with ſuch legal diſcernment and unbiaſſed judgment as will add a conſiderable portion of weight to its future deciſions. He not only ſhone in the character of a judge, but his patriotiſm and loyalty were equally conſpicuous. His zeal for the ſafety, welfare, and tranquillity of his country were on all occaſions apparent; but in no inſtances more than during the trying periods of the rebellion in behalf of the pretender, in the years 1715 and 1745: and for his reaſons, ſee his letter to the lord Lovat, who afterwards, for treaſonable conduct, ſuffered decapitation. Even in the vacations, he was conſtantly engaged with unwearied diligence in promoting the intereſts of agriculture, trade, and manufactures; and with unabated aſſiduity defending and promulgating the great truths of religion. After a life devoted to the cauſe of honour and virtue, and extended ſufficiently long for himſelf, though not for his country, he died in 1747, lamented by thoſe who had the pleaſure of his acquaintance, and regretted by all the friends of liberty and of truth. His lordſhip was well verſed in the original languages of the Scripture, particularly

ticularly the Hebrew,; as is evident from "a Letter to a Biſhop on the Writings and Diſcoveries of Hutchinſon," and which contains the cleareſt ſyſtematic view of that author's peculiar tenets ever yet publiſhed. He wrote alſo "Thoughts concerning natural and revealed Religion," and "Reflections on Infidelity;" the whole of which have been collectively printed in one volume, 12mo. 1750. His Thoughts on Religion and Letter to a Biſhop were tranſlated into French, by the celebrated writer Pierre Houbigant; and though containing ſentiments ſo repugnant to the national belief of France, yet they obtained a very extenſive circulation in that country. Life of Duncan Fourbes, 8vo. London Magazine for the year 1747. And Nouveau Dictionnaire Hiſtorique.

FORBES, in *Geography*, a town of Bohemia, in the circle of Bechin: 8 miles S.E. of Budweiſs.

FORBES's *Iſlands*, three iſlands in the South Pacific ocean, about 5 leagues from Bolt Head, a cape on the N.E. coaſt of New Holland. S. lat. 12° 25'.

FORBIN, CLAUDE, in *Biography*, a diſtinguiſhed French naval commander, was born in 1656, and entered the ſea-ſervice when he was very young. In 1686, he accompanied the French ambaſſador De Chaumont to Siam, and was left there as admiral of the country. Upon his return, he diſtinguiſhed himſelf in various actions in the Adriatic, the Channel, and the North ſea, and took prizes of great value. He became formidable to the Engliſh; attacked their fleet bound for Liſbon, took and deſtroyed part of the convoy, and captured ſeveral of the merchant ſhips. About the year 1708, he was the active friend of the pretender, and undertook to convey him ſafe to Scotland; but admiral Byng obliged him to retire. In 1710, a penſion being ſettled on him, he took up his reſidence near Marſeilles, where he died in 1733. Forbin was highly regarded by his country for courage and diligence in the diſcharge of his duty. He was generous and diſintereſted. Going to court to return thanks for a reward which the king had beſtowed upon him, he took occaſion to diſplay the ſervices of John Barth, the famous Dunkirk captain, whom he thought neglected. The liberality of his mind ſtruck the monarch ſo forcibly, that he exclaimed to his miniſter, that he rarely met with examples of this kind at his court. Forbin was author of "Memoirs," in 2 vols. 12mo. Moreri.

FORCADO, or RIO DE FORCADOS, in *Geography*, a river of Africa, which riſes far inland to the N.N.E., with many windings, in moſt places two miles wide, but of depth that allows only veſſels which draw ſeven or eight feet water. It runs into the Atlantic, 45 miles S.S.E. from the river Formoſa, N. lat. 6°.

FORCALQUIER, FORUM CALCARIUM, a town of France, and principal place of a diſtrict, in the department of the Lower Alps, ſituated in a delightful tract, watered by the Laye; formerly the capital of a country independent on Provence, and united to it in 1193; 7 leagues S.S.W. of Siſteron. The place, which is noted for three annual fairs, contains 2,539, and the canton 9,418 inhabitants, on a territory of 247½ kiliometres, in 14 communes. N. lat. 43° 57'. E. long. 5° 51'.

FORCAS, a town of Walachia; 3 miles N. of Caracalla.

FORCE, LA, a town of France, in the department of the Dordogne, on the Dordogne; the chief trade of which conſiſts in cattle, grain, and wine; 6 miles W. of Bergerac.

FORCE, in *Mechanics*. The nature of force being entirely unknown, it can only be defined by its effects. Whatever produces or tends to produce motion, or a change of motion in any body, is called a force. We are accuſtomed to conſider velocity as a meaſure of force, upon the ſuppoſition that under exactly ſimilar circumſtances the velocity is proportional to the force; an hypotheſis moſt highly probable, but not eaſily demonſtrable. Velocity is in itſelf a compound idea, ariſing from a certain relation between time employed and ſpace deſcribed. If a body A, ſuppoſed a material point, move uniformly, and without changing its direction from one point *a* to another *b*, the line *a b* is the ſpace deſcribed by the body A. If another body B move uniformly in the ſame manner from *c* to *d*, the line *c d* is the ſpace deſcribed by the body B. Now theſe ſpaces can eaſily be compared, either by their being repreſented or related to us in ſome ſtandard meaſure with which we are acquainted. In the ſame manner, the time in which each line is deſcribed may be defined by ſome known ſtandard meaſure, as a ſecond, a minute, &c.: the times and ſpaces may then be reſpectively expreſſed in abſtract numbers. And from conſidering the relation of theſe numbers to each other, has ariſen our idea of velocity, which in uniform motion is the relation between the ſpace and time employed to deſcribe it; and conſidering velocity as an abſtracted number, it is ſaid to be equal to the ſpace divided by the time. And thus different velocities may be compared.

Judging of force by its effect, we are naturally led to conſider velocity, or the ſpace deſcribed in a given time as its meaſure. But ignorant as we are of its nature, there is no mathematical contradiction in ſuppoſing that force may be expreſſed by other functions of the velocity, as for example, that it may be proportional to the ſquare or cube of the velocity. La Place has ſhewn, by a very ingenious inveſtigation, how we may experimentally be convinced of the proportionality of force to velocity, or at leaſt that ſince the difference *muſt be*, if any, extremely ſmall, it is highly improbable that any ſhould exiſt. It can be ſhewn, that if any conſiderable variation exiſted in this law, the relative motions of bodies on the earth's ſurface would be ſenſibly affected by the motion of the earth, that is, that the effect of a given force would vary very much according as its direction coincided with or was oppoſed to the direction of the earth's motion. The effects of the ſame apparent forces would vary likewiſe in different ſeaſons of the year, as the velocity of the earth is about one thirtieth greater in winter than in ſummer. Now ſince no variation of this kind is diſcernible, we may ſafely infer the proportionality of force to velocity. To comprehend the reaſoning on which the above concluſion is obtained, we may ſuppoſe two bodies moving upon one ſtraight line with equal velocities; and that by impreſſing on one of them a force which increaſes the primitive force, its relative velocity to the other body remains the ſame as if both of them had primitively been in a ſtate of repoſe. It is evident that the ſpace deſcribed by the body in conſequence of its primitive force, and of that which is added to it, becomes equal to the ſum of the ſpaces which each of them would have cauſed it to deſcribe in the ſame time, which ſuppoſes the force proportional to the velocity.

This law, and the law of *inertia*, which expreſſes the tendency of a body to perſevere in a ſtate either of reſt or motion, may be conſidered as derived from obſervation and experiment. They are the moſt ſimple and natural that can be imagined, and are ſufficient to ſerve as a baſis for the whole ſcience of mechanics.

The direction of a force is the ſtraight line which it tends to make a body deſcribe.

Conceiving two forces to act on a material point, it is

evident, that if the two forces act in the same direction, they will increase the effect of each other; but if they act in opposite directions, the point will only move in consequence of their difference, and it would remain at rest if the forces were equal. If the directions of the two forces make an angle with each other, the resulting force will take a mean direction, and it can be demonstrated geometrically; that if, reckoning from the point of intersection of the two directions of the forces, we take on these directions straight lines to represent them, and then form a parallelogram with these straight lines, its diagonal will represent, both as to its direction and magnitude, their resulting force. The resulting force thus determined (and which represents likewise the velocity of the moving point) may therefore be substituted as an equivalent force to the two composing forces; and reciprocally for any force whatever, we may substitute any two forces which, according to the above rule, would compose that force. Any force therefore may be decomposed into two others parallel to two axes situated in the same plane, and perpendicular to each other. To do this, it is sufficient to draw from the first extremity of the line representing the force two lines parallel to these axes, and to form with these lines a rectangle, the diagonal of which will be the force required to be decomposed. The two sides of this rectangle or parallelogram will represent the forces into which the given force may be decomposed parallel to these axes. If the force is inclined to a plane given in position, then taking to represent it a line in its direction, the extremity of which is on the surface of the plane, the perpendicular which falls from the other extremity will be the primitive force decomposed in the direction perpendicular to the plane. The straight line which in the plane joins the other extremity of the line representing the force with the perpendicular (or the orthographic projection of the line on the plane) will represent the primitive force decomposed parallel to the plane. This second partial force may be itself decomposed into two others, parallel to two axes in the same plane perpendicular to each other. Thus, every force may be decomposed into three others parallel to three axes perpendicular to each other, which axes are in the language of modern geometry called *rectangular co-ordinates*.

Hence arises a very simple method of having the resulting force of any number of forces, which are supposed to act upon a material point; for by decomposing every one of them into three others parallel to three axes given in position, and perpendicular to each other, it is clear that all the forces parallel to the same axis will be reduced to one single force, equal to the sum of the forces which act in one direction, minus the sum of those which act in a contrary direction: thus the point will be solicited by three forces perpendicular one to the other. If now three straight lines in each of their directions be taken to represent them, reckoning from the point of intersection (called the *origin of the co-ordinates*,) and on these straight lines we form a rectangular parallelopipedon, the diagonal of this solid will represent both the quantity and direction of the resulting force of all the forces which act upon the point.

This simple method has been uniformly followed by La Grange in the "Mechanique Analytique," and by La Place in the "Mechanique Celeste." It was first adopted by Maclaurin.

The principle of the composition of forces is of the most extensive utility in mechanics; it is sufficient alone to determine the law of equilibrium in every case. For by composing successively all the forces two by two, and taking the resulting force as a new force, we arrive at a force which must be equivalent to all the rest, and which, in case of equilibrium, must equal *zero*, when the system under consideration has no fixed point; but if there be an immoveable point by the conditions of the problem, then the resulting force arising from all the producing forces must necessarily pass through that point.

It is admitted by all writers on this subject, that the most abstruse propositions relating to the doctrine of forces may be deduced from a few simple principles; yet in the choice of these, few authors are found entirely to agree. The most natural and advantageous method seems to be that in which the relation which subsists between different forces in a state of equilibrium is first investigated, and then the consideration extended to a body in motion. In the case of a body solicited by several forces, but remaining in equilibrium, each force is supposed to produce only a tendency to motion, which tendency is measured by the motion it would produce, if it were not impeded by the action of the others; and expressing the effect of any one force by unity, the effect of the others relatively to this may be expressed by numbers or by lines.

La Place assumes only the two principles mentioned above, which he regards as experimental facts. Dr. Young, in his Lectures, is inclined to consider them as capable of demonstration; but this slight difference of opinion is but of small importance to the science, since all admit the same principles, and agree that they are established in the most satisfactory manner.

La Grange founds the whole doctrine of the equilibrium of forces on the well-known principle of the lever, on the composition of motion, and on the principle of virtual velocity. The principle of the lever may be derived from the composition of forces, and even from much less complicated considerations.

Archimedes is the earliest author upon record who attempted to demonstrate the property of the lever; he assumes the equilibrium of equal weights at equal distances from the fulcrum as an axiom in mechanics, and reduces to this simple and primitive case that of unequal weights, by supposing these, when they are commensurable, divided into equal parts, separated and placed on different points of the lever at equal distances, so that the whole lever may be loaded with a number of small equal weights at equal distances from the fulcrum.

The principle of the straight and horizontal lever being admitted, the law of equilibrium in other machines may be deduced from it: there is, however, some difficulty in referring the inclined plane to this principle; and the laws relating to it were, for a long time, unknown to mathematicians.

Stevinus, mathematician to prince Maurice of Nassau, was the first that gave a demonstration of it, by a very indirect, but at the same time a very curious method of reasoning.

He considers the case of a solid triangle resting upon its horizontal base; its sides then become two inclined planes: he then imagines a flexible chain consisting of a number of small equal weights threaded together, and so thrown over the triangle, that the upper part may rest on the two inclined planes, and the lower part hang suspended freely underneath, in the same manner as if attached to the lower extremities of the base. He then remarks, that if the chain is not in equilibrio, it will begin to slide along the plane, and the same cause subsisting, it should continue to slide for ever, producing a perpetual motion; but this implying a contradiction, we must conclude it to be in equilibrio, and if so, since the efforts of all the weights applied to one side exactly counterbalance all

thoſe applied to the other, and the number of weights are in the ſame ratio as the lengths of the planes; he concludes, that the weights will be in equilibrio on the inclined planes when they are to each other as the lengths of the planes: but when the plane is vertical, the power is equal to the weight; therefore, in every inclined plane, the power is to the weight as the height of the plane to its length.

The virtual velocity is that which a body in equilibrium is diſpoſed to receive, in caſe the equilibrium is diſturbed; or that which the body will really receive in the firſt inſtant of its motion: and the principle of virtual velocities, ſo much uſed by writers on the continent, in its moſt general form, is this. If a ſyſtem, compoſed of any number of bodies or points which are drawn in any direction by any forces whatever, be in equilibrium, and a ſmall motion be given to the ſyſtem by virtue of which every point deſcribes an infinitely ſmall ſpace, which will expreſs its virtual velocity, then the ſum of the forces, multiplied each by the ſpace deſcribed by the point to which it is applied, in the direction of the force, will be equal to zero; eſtimating as poſitive the ſmall ſpaces deſcribed in the direction of the forces, and negative thoſe deſcribed in a contrary direction.

Galileo ſeems to have been the firſt writer on mechanics who was acquainted with this principle, in his treatiſe, "Della Scienza Mecanica," and in his dialogues he propoſes it as a general property in the equilibrium of machines.

Des Cartes likewiſe deduced the equilibrium of different forces from a principle ſimilar to the above, but preſented under another point of view, and ſomewhat leſs general According to him, neither a greater nor leſs force is required to lift a weight to a certain height, than to lift an heavier weight to a height proportionally leſs, or a ſmaller weight to a height proportionally greater. So that two weights will be in equilibrio, when the perpendicular ſpaces deſcribed by them are reciprocally proportional to the weights; but in the application of this principle we muſt only conſider the ſpaces deſcribed in the firſt inſtant of motion, or we ſhall not attain the accurate law of equilibrium.

Torricelli, the celebrated diſciple of Galileo, is the author of another principle, which is nearly to the ſame effect, or is rather a neceſſary conſequence of the principle of Galileo. It is, that when two weights are ſo connected, that, being placed in any manner, their centre of gravity neither riſes nor falls; then in all theſe ſituations they will be in equilibrio. Torricelli applies this principle to the inclined plane, but it can be demonſtrated to hold good in all machines generally. From this ariſes another principle, which ſome authors have recurred to, to ſolve various problems relating to the equilibrium of forces. When a ſyſtem of ponderable bodies is in equilibrio, the centre of gravity is the loweſt poſſible. For it can be ſhewn by the theory "De Maximis & Minimis," that the centre of gravity of a body is the loweſt, when the differential of its deſcent is zero; that is, when the centre of gravity neither aſcends nor deſcends by an infinitely ſmall change in the poſition of the ſyſtem.

John Bernouilli is the firſt author who perceived the great utility of generalizing this principle of virtual velocity, and applying it to the ſolution of problems, as may be ſeen in one of his letters to Varignon, dated 1717, and which this latter has inſerted in the ninth ſection of his "Nouvelle Mechanique," which is entirely employed in ſhewing the truth of this principle, and its great utility when applied to the ſolution of different caſes in ſtatics.

From the ſame ſource originated another principle, propoſed by Maupertuis in the Memoirs of the Academy for 1740, under the name of the "Law of Repoſe," and which was afterwards extended by Euler, and explained in the Memoirs of the Academy of Berlin for 1751. Of the ſame nature is the principle aſſumed by M. Courtivron in the Memoirs of the Academy for 1748 and 1749; and which conſiſts in this, that of all the ſituations which a ſyſtem of bodies can ſucceſſively take, that in which the *vis viva* is a maximum or minimum is likewiſe that in which the ſyſtem muſt be placed, to remain in equilibrio; the *vis viva* of a ſyſtem being defined the ſum of the reſpective maſſes of which the ſyſtem is compoſed, multiplied each into the ſquare of its velocity.

But of all theſe methods, that of virtual velocity (from which indeed all the others are derived) ſeems to be the moſt generally uſeful. Practical examples of the analytic proceſſes, by which general formulæ or equations for the equilibrium of any ſyſtem of forces may be determined, are given by La Grange; and La Place demonſtrates the principle on which the calculus is founded.

It ſhould be obſerved that force is here ſuppoſed to be the product of the maſs of a material point, by the velocity it would receive if entirely free. If we confine theſe conſiderations to the caſe of a ſingle material point, the conditions of equilibrium will be found analogous to thoſe above-mentioned, but much ſimplified.

The moſt elementary equation to expreſs the ſtate of equilibrium of a material point acted on by any number of forces is, that every force multiplied by the element of its direction is equal zero; that is, if we ſuppoſe the point to change its poſition an infinitely ſmall quantity in any direction, then in the caſe of equilibrium, if every force be multiplied by the elementary ſpace which the point has approached to, or receded from, the force eſtimated in its direction, the product will be zero.

This ſuppoſes the point or particle free; but if it is conſtrained to move on a curve ſurface, it will then experience a re-action from this ſurface equal and contrary to the preſſure which the particle exerts on the ſurface, and which will be perpendicular to it, or in the direction of the radius of the curve. This re-action, therefore, may be conſidered as a new force, and the re-action multiplied by the elements of its direction muſt be added to the former equation; but if the variation of poſition, inſtead of being taken arbitrarily, be taken upon the curve, ſo as not to alter the conditions of the problem, ſince the elementary variation of the radius is evidently equal to zero, the preceding equation ſtill holds good.

Moreover, if the magnitude or intenſity of any force, multiplied by the diſtance of its direction from any fixed point, be called its *moment* relative to that point, then it is found that the ſum of the moments of the producing forces is always equal to the moment of the reſulting force; and in the caſe of equilibrium, the ſum of the moments of all the forces is equal to zero.

When the forces which act on a point, or a body, or a ſyſtem of bodies, are not ſo proportioned as to maintain the ſyſtem in equilibrium, motion neceſſarily takes place, and the laws of this motion may be deduced by extending the principles which were employed in the inveſtigation of the ſtate of equilibrium: this is the method employed by La Grange, and ſubſequently by La Place. La Grange, with the principle of virtual velocities, combines the principle of d'Alembert, which is extremely ſimple; indeed it may be

conſidered

conſidered as an axiom, but which, though very obvious, remained long unobſerved.

It is this: if ſeveral bodies have a tendency to motion, with velocities and in directions which they are conſtrained to change, in conſequence of their reciprocal action on each other, then theſe motions may be conſidered as compoſed of two others, one which the bodies actually take, and the other ſuch, that had the bodies been acted on by theſe alone, they would have remained in equilibrium.

To illuſtrate this theorem by an example; ſuppoſe two unelaſtic bodies or balls, whoſe maſſes are M and m, meet in the ſame direction with velocities V, v, reſpectively, required the common velocity after the ſhock.

Decompoſe the velocity V into x and $V - x$,
and the velocity v into x and $v - x$.

The velocities $V - x$ and $v - x$ will be deſtroyed, but as they alone would have maintained the bodies in equilibrio, they muſt be inverſely as their maſſes; hence but one in this caſe muſt be taken with the contrary ſine: hence

$$V - x : -v + x :: m : M$$
$$MV - Mx = -mv + mx$$
$$MV + mv = Mx + mx$$
$$x = \frac{MV + mv}{M + m}.$$

If a body or material point M (*Plate* XXVIII. *Mechanics*, *fig.* 6.) be ſuppoſed to move from A to B in the line AB by the action of ſome accelerating force P, its velocity, during any ſmall elementary ſpace bq, may be conſidered as uniform, and expreſſed by $\frac{dx}{dt}$, x being the ſpace at the time at the commencement of a new inſtant dt, (in which is deſcribed the ſpace qr). The increaſe of force or velocity which M receives may be expreſſed by $P \cdot dt$; P repreſenting the intenſity of the force. The velocity, therefore, at the *commencement* of this new inſtant, will be $\frac{dx}{dt} + P \cdot dt$; but this initial velocity may, by d'Alembert's theorem, be decompoſed into two others, of which one will remain and the other be deſtroyed; and the velocity deſtroyed will be ſuch, that if M had been ſolicited by that alone, it would have remained in equilibrium. Now the velocity remaining is evidently $\frac{dx}{dt} + d \cdot \frac{dx}{dt}$, and the velocity deſtroyed therefore $P \cdot dt - d \cdot \frac{dx}{dt}$; ſince theſe two quantities together equal $P \cdot dt + \frac{dx}{dt}$.

If the point M therefore had been ſolicited only by the force $P \cdot dt - d \cdot \frac{dx}{dt}$, it would have remained in equilibrium; hence

$$P \cdot dt - d \cdot \frac{dx}{dt} = 0$$

$$\text{and } P = \frac{d^2x}{dt^2}.$$

which is the general differential expreſſion for the accelerating force.

Since two forces $P \cdot dt$, and $d \cdot \frac{dx}{dt}$, acting on the point M, keep it in equilibrium, then if the point be ſuppoſed to vary its poſition an infinitely ſmall quantity δx, which may be here taken equal dx, according to the elementary theorem of La Place, each force multiplied into the element dx ſhould equal zero; hence $dx \left\{ d \cdot \frac{dx}{dt} - P \cdot dt \right\} = 0$.

And by integration $\frac{d^2x}{dt^2} = C +$, twice the integral of $P \cdot dx$. But $\frac{d^2x}{dt^2}$ is the ſquare of the velocity. Therefore the ſquare of the velocity is always equal to twice the integral of the accelerating force multiplied into the element of the ſpace; or according to our notation $v\dot{v} = F \cdot \dot{x}$; a theorem of extenſive application in the doctrine of accelerating forces. This principle is analogous to that which, when extended to a ſyſtem of bodies, is called the principle of the conſervation of the *vis viva*.

In the above examples we may obſerve that the theorem of d'Alembert is not of itſelf ſufficient to ſolve a problem, ſince it is always neceſſary to derive ſome condition relating to the equilibrium from other conſiderations. The difficulty of determining the forces, and the law of the equilibrium of theſe forces, renders this application ſometimes more difficult, and the proceſs more tedious, than if the ſolution were performed by ſome principle leſs ſimple and direct.

It was by combining the above principle of d'Alembert with that of virtual velocity, that La Grange was enabled to deduce the general equations relating to the forces which act on a ſyſtem of bodies. He thus deſcribes the nature of the method.

To form an accurate conception of the manner in which theſe principles are applied, we ſhould recollect that the general principle of virtual velocity conſiſts in this; that when a ſyſtem of material points, ſolicited by any force, is in equilibrium, if the ſyſtem receive a ſmall alteration in its poſition, by virtue of which every point deſcribes an infinitely ſmall ſpace, the ſum of each force, multiplied by the ſpace deſcribed by the point to which it is applied, according to the direction of the force, is always equal to zero.

If now we conſider the ſyſtem as in motion, and ſuppoſe the motion which every point has during an inſtant as compoſed of two, of which one is that which the point has the following inſtant, then it follows that the other muſt be deſtroyed by the reciprocal action of the points or bodies upon each other, and by that of the moving forces by which they are ſolicited. Thus there will be an equilibrium between theſe forces, and the preſſures or reſiſtances which reſult from the motions which are loſt by the bodies from one inſtant to another. Hence it follows, that to extend to the motion of a ſyſtem of bodies, the formulæ of its equilibrium, it is ſufficient to add the terms due to theſe laſt-mentioned forces.

If now we conſider the velocities which every particle has in the direction of three fixed rectangular co-ordinates, the decrement of theſe velocities will repreſent the motions loſt in theſe directions, and their increments will be the motions loſt in the oppoſite directions. Therefore the reſulting preſſures or forces of theſe motions deſtroyed will be expreſſed in general by the maſs multiplied into the element of the velocity, and divided by the element of the time, and their directions will be directly oppoſite to thoſe of the velocities.

By theſe means the terms required may be expreſſed analytically, and a general formula obtained for the motion of a ſyſtem of bodies, which will comprehend the ſolution of all the problems in dynamics, and of which a ſimple expanſion will give the neceſſary equations for each problem.

But one of the greateſt advantages derived from the formula thus obtained is, that it gives directly a number of

general equations, which contain the principles or theorems known under the appellations of the

Conſervation of the *vis viva*,
Conſervation of the motion of the centre of gravity,
Conſervation of equal areas,
And the principle of the leaſt action.

The firſt of theſe principles, the conſervation of the *vis viva*, was diſcovered by Huygens, but under a form ſomewhat different to that which we now give it. The principle, as employed by him, conſiſted in the equality between the aſcent and deſcent of the centre of gravity of ſeveral ponderable bodies which deſcend conjointly, and afterwards aſcend ſeparately by the velocity each had acquired. Now by the known properties of the centre of gravity, the ſpace deſcribed by it in any direction is expreſſed by the ſum of the products of the maſs of each body, by the ſpace it has deſcribed in the ſame direction, divided by the ſum of the maſſes. On the other hand, by the theorems of Galileo, the vertical ſpace deſcribed by a heavy body in its deſcent is proportional to the ſquare of the velocity acquired, and with which it will aſcend to the ſame height: thus the principle of Huygens is reduced to this, that in the motion of a ſyſtem of bodies, the ſum of the maſſes by the ſquares of the velocities at every inſtant is the ſame, whether the bodies have deſcended conjointly in any manner whatever, or have each deſcended freely through the ſame vertical heights. Hitherto this principle had only been regarded as a ſimple theorem of mechanics; but when J. Bernouilli had adopted the diſtinction eſtabliſhed by Leibnitz, between the preſſures which act without producing actual motion, and the living forces, as they were termed, which produced motion, as likewiſe the meaſure of theſe forces by the products of the maſſes by the ſquares of the velocities, he ſaw nothing in the principle in queſtion but a conſequence of the theory of the *vis viva*, and a general law of nature; in conſequence of which the ſum of the *vis viva* of ſeveral bodies preſerves itſelf the ſame as long as they act on each other by ſimple preſſures, and is always equal to the ſimple *vis viva* reſulting from the action of the actual forces which move the body. He gave it the name of the "conſervatio virium vivarum," and employed it with ſucceſs in the ſolution of ſeveral problems that before him had not been effected.

His ſon, the celebrated D. Bernouilli, afterwards deduced from this principle the law of the motion of fluids in vaſes, a ſubject which before had only been treated in a vague and unſatisfactory manner. In the Berlin memoirs for 1748, he explained and rendered this principle very general, ſhewing how it might be applied to the motion of bodies ſolicited by mutual attraction, or drawn towards fixed centres by forces proportional to any function of the diſtance whatever.

The advantage of this principle conſiſts in its affording immediately an equation between the velocities of the bodies and the variable quantities which determine their poſition in ſpace, ſo that when by the nature of the problem theſe variable quantities are reduced to one, this equation alone is ſufficient for its ſolution, which is the caſe in that relating to the centre of oſcillation. In general the conſervation of the *vis viva* gives always a firſt integral of the different differential equations of each problem, which is often of great utility.

The ſecond principle is that of Newton, given as an elementary propoſition in his "Principia." He demonſtrates, that the ſtate of repoſe or motion of the centre of gravity of ſeveral bodies, is not altered by the reciprocal action of theſe bodies in any manner whatever; ſo that the centre of gravity of bodies which act upon each other either by cords or levers, or by the laws of attraction, independent of any exterior action or obſtacle, remains always in repoſe, or moves uniformly in a ſtraight line.

D'Alembert has extended this theorem, and ſhewn that if every body of the ſyſtem is ſolicited by a conſtant accelerating force acting either in parallel lines or directed towards a fixed point, and varying with the diſtance, the centre of gravity will deſcribe the ſame curve as if the bodies were free; and it might be added, that the motion of this centre will be the ſame as if all the forces of the bodies were applied to it each in its proper direction.

It is evident that this principle ſerves to determine the motion of the centre of gravity, independently of the reſpective motions of the bodies, and thus it will always afford three finite equations between the co-ordinates of the bodies and the times, and which will be the integrals of the differential equations of the problem.

The third principle is much leſs ancient than the two preceding, and appears to have been diſcovered about the ſame time by Euler, Bernouilli, and the chevalier d'Arcy, but under different forms.

According to the two firſt, the principle conſiſts in this, that in the motion of ſeveral bodies about a fixed centre, the ſum of the products of the maſs of each body, by the velocity of rotation round the centre, and by its diſtance from the ſame centre, is always independent of any mutual action which the bodies may exert upon each other, and preſerves itſelf the ſame as long as there is no exterior action or obſtacle. Daniel Bernouilli gave this principle in the firſt volume of the Memoirs of the Academy of Berlin, in 1746, and d'Alembert the ſame year, in his "Opuſcula." The principle of M. d'Arcy, as given to the Academy of Paris in 1746, but not printed till 1752, is, that the ſum of the products of the maſs of each body, by the area traced by its radius vector about a fixed point, is always proportional to the times. This principle is nothing more than a generalization of the beautiful theorem of Newton, of the equality of areas deſcribed by centripetal forces, and to perceive the analogy, or rather identity, with that of Euler and Bernouilli, it is ſufficient to recollect that the velocity of rotation is expreſſed by the element of the circular arc divided by the element of the time, and that the firſt of theſe elements multiplied by the diſtance from the centre, gives the element of the area deſcribed about this centre; ſo that this laſt principle is only the differential expreſſion of that of M. d'Arcy. This author afterwards gave this principle another form, which renders it more ſimilar to the preceding. The ſum of the products of the maſſes by the velocities, and by the perpendiculars drawn from the centre to the direction of the forces, is always a conſtant quantity.

Under this point of view he eſtabliſhed a ſpecies of metaphyſical principle, which he calls the conſervation of action, to oppoſe, or rather ſubſtitute it for, the principle of the leaſt action, as if theſe vague and arbitrary denominations could conſtitute the eſſence of the laws of nature, or by ſome ſecret virtue could raiſe ſimple reſults of the known laws of mechanics to the rank of final cauſes.

But however this may be, the principle in queſtion takes place in every ſyſtem of bodies which act on each other in any manner whatever, whether by cords, inflexible lines, attractions, &c. and moreover ſolicited by forces directed to a centre; and this, whether the ſyſtem be entirely free, or conſtrained to move about this centre. The ſum of the products of the maſſes by the areas deſcribed about this centre, and projected on any plane whatever, is always proportional to the time; ſo that referring theſe areas to three rectangular

rectangular planes, three differential equations are obtained of the firſt order between the time and the co-ordinates of the curves deſcribed by the bodies; and it is, properly, in theſe equations that the nature of the principle exiſts.

The fourth principle is that of the leaſt action, ſo called by Maupertuis, and which the writings of ſeveral illuſtrious authors have ſince rendered celebrated. Conſidered analytically the principle is this, that in the motion of bodies which act one upon the other, the ſum of the products of the maſſes by the velocities, and by the ſpaces deſcribed, is a minimum. The author has deduced from it the laws of reflection and refraction of light, as likewiſe thoſe of the ſhock of bodies, in two memoirs, one of the Academy of Sciences for 1744, the other two years afterwards, in thoſe of Berlin.

But it muſt be confeſſed, that theſe applications are too partial to eſtabliſh the truth of a general principle, and, beſides, have ſomething in them too vague and arbitrary, which renders the conſequences uncertain as to the exactneſs of the principle itſelf: ſo that this principle ought not to be claſſed with thoſe above explained. But there is another point of view in which it may be conſidered more general and exact, and which alone merits the attention of geometricians. Euler gave the firſt idea at the end of his treatiſe on Iſoperimetrical problems printed at Lauſanne in 1744, ſhewing that in trajectories deſcribed by central forces, the integral of the velocity multiplied by the element of the curve is always a maximum or a minimum.

This property, as explained above, was only known by Euler to belong to inſulated bodies; La Grange extended it afterwards to the motion of bodies which act on each other in any manner whatever. And there reſults this new general principle, that the ſum of the products of the maſſes by the integrals of the velocities, multiplied by the elements of the ſpaces deſcribed, is conſtantly a maximum or a minimum.

By combining this principle with that of the conſervation of the *vis viva*, a ſolution of many difficult problems in dynamics may be obtained. Examples are to be found by La Grange in the ſecond volume of the Memoirs of the Academy of Turin.

Such is the general outline of the hiſtory and nature of the principles of dynamics, as given by La Grange. The ſubject is treated much in the ſame manner by La Place in the "Mechanique Celeſte," but the inveſtigation is carried ſtill further. With La Grange he adopts the principle of d'Alembert, and reſolves every motion into two, one which the particle had in the preceding inſtant, and the other ſuch as would have ſuſtained it in equilibrio.

La Place, however, differs from La Grange in not admitting the principle of virtual velocity to be aſſumed as a fundamental axiom, but demonſtrates it by a regular train of inductions; having eſtabliſhed nearly the ſame formulæ or differential equations, and deduced all the above general principles in the manner already deſcribed.

In addition to theſe principles others, in the nature of corollaries, are introduced, many of which are very deſerving of attention. From the principle of the conſervation of areas it follows, that in the motion of a ſyſtem of bodies ſolicited only by their mutual attraction, and by forces directed to the origin of the co-ordinates, there exiſts a plane paſſing through this origin, and which poſſeſſes theſe remarkable properties. 1. That the ſum of the areas, traced on this plane by the projections of the radii vectores of the bodies, and multiplied by their reſpective maſſes, will be the greateſt poſſible. 2. That this ſame ſum is equal to zero upon all the planes perpendicular to it. As the principle of the *vis viva*, and of areas ſubſiſts relatively to the centre of gravity, even ſuppoſing it to have a rectilinear and uniform motion; it follows, that a plane may be determined paſſing through this moveable origin, on which the ſum of the areas, deſcribed by the projections of the radii vectores, and multiplied reſpectively by their maſſes, may be the greateſt poſſible. It appears, that this plane is parallel to that which paſſes through the fixed origin, and ſatisfies the ſame conditions: moreover, a plane paſſing through the centre of gravity, and determined according to the preceding conditions, remains always parallel to itſelf during the motion of the ſyſtem, a circumſtance of great importance and utility. It may be added, that any plane parallel to this, and paſſing through any one of the bodies, poſſeſſes analogous properties.

La Place proceeds to examine in what manner theſe reſults would be changed, by ſuppoſing other relations to ſubſiſt between the force and velocity. Force may be expreſſed in an infinite number of ways relatively to the velocity beſides the ſimple law of proportionality, without implying any mathematical contradiction. If the force be ſuppoſed to be ſome other function of the velocity, (expreſſed analytically thus, $F = \phi v$) then the principle of the *vis viva* is found to obtain in all the relations mathematically poſſible between the force and velocity; the *vis viva* of a body being defined the product of its maſs, by the double of the integral of its velocity, multiplied by the differential of the function of the velocity which expreſſes the force.

It is in the law of nature only, that the motion of the centre of gravity is preſerved uniform and rectilinear.

The conſervation of areas, likewiſe, would not ſubſiſt in any other law than in that of nature; but a principle, analogous to that of the leaſt action, will be found to belong to every poſſible relation between force and velocity.

This principle of the leaſt action is not ſo obvious as others we have mentioned, being much more remote from the elementary theorems from which they are all derived; but if it can be directly and mathematically deduced from the ſame ſimple principles, it can have no more claim to the dignity of a final cauſe than any other remarkable property of numbers, ſince the reverſe would imply a mathematical contradiction. The fact, however, is curious, and deſerving of attention; it may be analytically ſtated thus: ſuppoſe a material point, in conſequence of the action of ſeveral forces, to move from one point to another, then the path or curve deſcribed is found to have this remarkable property, that the integral or continued product of the velocity (as determined by previous conſiderations) multiplied into the element of the curve, will be leſs than in any other curve paſſing through the ſame points. As this propoſition can only be intelligible to thoſe who are in ſome degree familiar with the language of the differential calculus, we ſhall endeavour to illuſtrate it by taking a particular caſe as an example. Let us ſuppoſe the point M (*fig.* 2.) projected horizontally in the direction M *s*, and at the ſame time attracted by the force of gravity in the direction M S; its path, as is well known, will be the parabola M M'. At any point *m*, if x be aſſumed to expreſs the diſtance M *m'*, the velocity at that point, *m*, will be expreſſed by $\sqrt{h + x}$; *h* being ſome conſtant quantity previouſly determined, and in this inſtance depending on the force of gravity and on the force of projection. Now, if we conceive the curve M M' to be divided into an infinite number of ſmall portions or elements, and that each of theſe be multiplied by the expreſſion $\sqrt{h + x}$, which denotes the velocity, and which will have a different value for every element into which it is to be multiplied, then it is aſſerted, that the ſum of all theſe ſmall factors, (or what in the language of analyſis is called their *integral*) will be leſs than if the ſame operation had

had been performed on any other line or curve paſſing through M M′. It may appear, at firſt ſight, that the ſum of theſe factors would have been leſs had the body moved from M to M′ by the ſhorteſt path, or in the ſtraight line M M′. Let us examine this caſe, and ſee whether we ſhould, by this ſuppoſition, inevitably obtain a leſs product than by the former one. If we divide the line into the ſame number of ſmall elements as the curve, it is evident that each of theſe will be ſmaller, and ſo far our object being to obtain a minimum, the advantage is in favour of the ſtraight line; but if we examine the multipliers $\sqrt{h+x}$, we ſhall find that they increaſe rapidly in value as they deſcend, and if we conſider the figure, we may obſerve that in the ſtraight line half the elements are multiplied by greater values of $\sqrt{h+x}$. Now this effect is obviated by the curve, as the greater number of its elements are placed in the upper part of the figure, where the multipliers $\sqrt{h+x}$ are comparatively but of ſmall value. Were the curve however to be made too convex, as the dotted line in the figure, this advantage might be deſtroyed by the increaſed value of the elements, which might more than counterbalance the effect of the diminiſhed values of $\sqrt{h+x}$. It will not be difficult now to comprehend the exiſtence of ſome curve, in which the ſum of the factors thus determined ſhall be leſs than in any other. In the preſent caſe it is found to be a parabola, and in every inſtance it can be ſhewn, that the curve anſwering to the above conditions of a minimum, is identical with that which a body is known to deſcribe by the uſual rules of mechanical inveſtigation. Admitting, therefore, the principle of the leaſt action as an eſtabliſhed theorem, problems may be ſolved by it, and the trajectories of bodies moving in ſpace determined; but it is of very little practical utility, ſince the neceſſary calculations are much more complex and difficult than the more uſual methods of inveſtigation. The reader will find ſome inſtances of theſe ſolutions under the article of *Analytic* FUNCTION. See likewiſe ISOPERIMETRICAL *Problems*.

The above explanation refers only to the caſe of a ſingle body, nor did Maupertuis, the inventor of this principle, extend it farther. Euler eſtabliſhes the generality of this principle in his treatiſe on the Iſoperimetrical problems, and ſhews that in all trajectories deſcribed by the action of centripetal forces, the integral of the velocity, multiplied by the element of the curve, is always a maximum or a minimum. La Grange firſt extended this principle to a ſyſtem of bodies, acting on each other, and demonſtrated, that the ſum of the products of the maſſes by the integrals of the velocities, multiplied by the elements of the ſpaces deſcribed, is always either a maximum or a minimum.

Theſe are the great and leading principles of the doctrine of forces, which have been at different times excogitated by the moſt eminent writers on theſe ſubjects; moſt of them are nothing more than developements of theorems eaſily derived from the Newtonian laws of motion, and many of them eſtabliſhed indeed by Newton himſelf; but there is a great advantage in this generalization of mechanical principles, as it enables us to take a more enlarged and comprehenſive view of the ſubject, than when the attention is confined to the detail of a ſingle problem.

Forces, which become the ſubject of mathematical computation, may very properly be divided into three ſeparate claſſes.

1ſt. Thoſe which, acting inſtantaneouſly, or at leaſt for a ſhort interval of time, impart uniform motion to a particle on which they act, provided it be not ſolicited by any other force, and at the ſame time free to move in any direction.

2d. Forces which act conſtantly, and whoſe intenſity remains the ſame: a material particle, free to obey the action of ſuch a force, deſcribes its path with a motion *uniformly accelerated*.

3d. Forces whoſe intenſities are continually varying, but according to ſome known law. The motion produced by the action of theſe forces is very complicated, and the circumſtances relating to it can only be inveſtigated by means of the integral calculus, or by ſome analogous methods.

Every force, whoſe mode of action is too arbitrary and uncertain to be included in either of the above claſſes, may be conſidered as in great meaſure foreign to the preſent ſubject of inveſtigation.

Caſe 1. When the forces meet in the ſame point.

When ſeveral forces, as P, Q, S, &c. (*fig.* 3.) whoſe directions are M P, M Q, M S, and intenſities M *a*, M *b*, M *c*, are exerted on any point M, the reſulting force is eaſily obtained, by combining the forces by parallelograms two and two, till a final reſulting force is obtained, which in this caſe, as appears by the figure, is in the direction M R, and whoſe magnitude is the diagonal M *d*. This proceſs may be ſimplified by taking M *a* (*fig.* 4.) equal and parallel to any force P, *a b* equal and parallel to any force Q, *b c* to a force S, &c. then M *c* ſhall be the reſulting force. If the forces terminate in M, after being carried round in a polygon, it would indicate that the point M was in equilibrium; and it is evident that if for the reſulting force we ſubſtitute its equal, in a contrary direction, the point M will likewiſe be in equilibrium.

Neither of theſe methods are of great practical utility, though extremely well adapted to illuſtrate the principle on which forces are eſtimated; we are therefore to conſider by what mode they may moſt commodiouſly be introduced into analytic calculation.

Let the angle P M R (*fig.* 5.) $= \theta$, Q M R $= \varepsilon$
M *a d* $= \alpha$, then P : Q :: ſin. ε : ſin. θ
P : R :: ſin. ε : ſin. α
Q : R :: ſin. θ : ſin. α.

$$\text{Therefore } \frac{P}{\text{ſin. }\varepsilon} = \frac{Q}{\text{ſin. }\theta} = \frac{R}{\text{ſin. }\alpha}.$$

Hence three forces are in equilibrio, when each is proportional to the ſine of the angle formed by the direction of the two others. Since the direction of the reſulting force depends only on the ratio, and not on the abſolute magnitude of the producing forces, it follows that if ſeveral forces are in equilibrium, and they are made to vary proportionally, they will ſtill remain in equilibrium.

If P $=$ Q; $\varepsilon = \theta$; and R $= 2$ P cos. θ

If the direction of the forces P, Q, are at right angles.

Then $R^2 = P^2 + Q^2$
And P $=$ R cos. θ
Q $=$ R ſin. θ
Q $=$ P . tang θ.

Theſe equations are often of great utility in transforming forces into others that are rectangular. For to reſolve any force R into two others which ſhall be rectangular, it is ſufficient to obſerve that P $=$ R cos. θ, Q $=$ R ſin. θ, or that each producing force is the product of the reſulting force R, by the coſine of the angle which it makes with this producing force.

Hitherto we have ſuppoſed the forces to act in one plane. Suppoſe now three forces P, Q, S, acting on the point M in directions not in the ſame plane, and firſt let theſe directions be rectangular, that is, let P and S be at right angles, and Q perpendicular to their plane. The producing forces P and S, the reſulting force T, determined by the equations P $=$ T cos θ; S $=$ T ſin. θ, where θ is the angle formed by T and P. In the ſame manner Q and T have their reſulting

ing force R, given by the equations R fin. $\gamma = T$; R cos. $\gamma = Q$; γ being the angle formed by R and Q. Subſtituting R fin. γ for T in the two firſt equations, we have $P = R$ cos. θ. fin. γ; $S = R$ fin. θ. fin. γ; $Q = R$ cos. γ.

The ſum of the ſquares of theſe equations gives $R^2 = P^2 + Q^2 + S^2$. The values of θ and γ are eaſily found, which compleat the problem. It is more convenient to employ the angles α, β, and γ, which the direction of the reſulting force R forms with the reſpective forces P, S, and Q. Now it is known that cos. θ. fin. γ = cos. α; and fin. θ. fin. γ = cos. β. Therefore, inſtead of the preceding equations, we have $P = R$ cos. α; $S = R$ cos. β; $Q = R$ cos. γ; from whence α, β, γ, are obtained.

General caſe in which the forces are ſuppoſed to have any directions whatever in ſpace.—Let A S, A P, A Q, (*fig.* 6.) be three rectangular co-ordinates paſſing through any arbitrary point A: let A P be the axis of x, A S that of y, and A Q of z. The plane P A S will be the plane of $x\,y$ (ſee *Analytic* GEOMETRY), S A Q that of $y\,z$, and P A Q that of $x\,z$. Of theſe axes two, as x, y, may be ſuppoſed horizontal, and z vertical.

Let the forces be repreſented by P′, P″, P‴, &c. whoſe directions form with the axis of

x	the angles	-	α', α'', α'''
y	-	-	β', β'', β'''
z	-	-	γ', γ'', γ'''.

By reſolving each of theſe forces into three others, whoſe directions are parallel to the axes, we have for the producing forces parallel to the axes

x	P′. cos. α',	P″. cos. α'',	P‴. cos. α'''
y	P′ cos. β',	P″ cos. β'',	P‴ cos. β'''
z	P′ cos. γ',	P″ cos. γ'',	P‴ cos. γ'''

Each of theſe collections of forces are equivalent to a ſingle force, equal to their ſum. Since they are in the direction of the ſame ſtraight line, let X, Y, Z, be the three forces parallel to the reſpective axes, and we have

$$X = P' \cos. \alpha' + P'' \cos. \alpha'' + P''' \cos. \alpha'''$$
$$Y = P' \cos. \beta' + P'' \cos. \beta'' + P''' \cos. \beta'''$$
$$Z = P' \cos. \gamma' + P'' \cos. \gamma'' + P''' \cos. \gamma'''$$

Let α, β, γ, be the unknown angles which the reſulting force R forms with the three axes; then R cos. α, R cos. β, R cos. γ, will be the equivalent producing forces in the directions of x, y, z; hence R cos. $\alpha = X$, R cos. $\beta = Y$, R. cos. $\gamma = Z$.

To obtain the value of R and its direction, add together the ſquares of theſe equations, and R^2 (cos.^{2} α + cos.^{2} β + cos.^{2} γ) = $X^2 + Y^2 + Z^2$, but cos.^{2} α + cos.^{2} β + cos.^{2} $\gamma = 1$: therefore

$$R = \sqrt{(X^2 + Y^2 + Z^2)} \text{ and}$$
$$\cos. \alpha = \frac{X}{R}, \quad \cos. \beta = \frac{Y}{R}, \quad \cos. \gamma = \frac{Z}{R}.$$

which equations indicate that the reſulting force is the diagonal of a parallelopiped, whoſe three edges are X, Y, and Z.

Let now x', y', z', be the co-ordinates of the point to which theſe forces are applied, the projections of the reſulting force upon the three co-ordinate planes will paſs through that of the point. The equations of the projections of this line will therefore be

$y - y' = a\,(x - x')$	upon the axis of $x\,y$
$z - z' = b\,(x - x')$	$x\,z$
$b\,(y - y') = a\,(z - z')$	$y\,z$

a and b being the tangents of the angles which the axis of x forms with theſe projections on the planes of $x\,y$ and $x\,z$. If, therefore, through the point A, the lines A P, A S, A Q, be drawn parallel to the axes x, y, z, the projection for the reſulting force R, on the plane P A S, will be A T; therefore, the tangent a of the angle T A P = θ,

$$\text{or tang. } \theta = \frac{Y}{X} = a.$$

In the ſame manner $\frac{Z}{X} = b$.

The equations of the projections are therefore

$$\left.\begin{array}{l} X\,(y - y') = Y\,(x - x') \\ Y\,(z - z') = Z\,(x - x') \\ Z\,(y - y') = Y\,(z - z') \end{array}\right\}$$

If the ſyſtem be in equilibrium,

$$X = o, \quad Y = o, \quad Z = o.$$

On parallel forces.—Previouſly to the conſideration of parallel forces, it will be neceſſary to notice a very ſimple geometrical propoſition, and which forms, in fact, the baſis of what La Place and other French writers call the "Theorie des Moments." The terms momentum and moment have been uſed by different authors to expreſs very different ideas. It is often uſed to expreſs the effort, action, energy, or impetus of a power to communicate motion to a body or ſyſtem of bodies; but modern writers, particularly the mathematicians of the continent, underſtand by moment the product of a power or force multiplied by the diſtance of its direction from a given point, line, or plane.

If a point E, (*fig.* 7.) be taken any how ſituated with reſpect to the parallelogram A B C D, and the perpendiculars E F, E G, E H, be drawn from E to the two ſides, and to the diagonal, A D × E G will be equal to A C × E H + A B × E F. Join E A, E B, E D. Produce D B to I; I H = D L will be the height of the triangle A C D, A C being the baſe.

$$\triangle E A D = \frac{A D \times E G}{2}$$

$$\triangle E A B = \frac{A B \times E F}{2}$$

$$\triangle A B D = A C D = \frac{A C \times I H}{2}$$

$$\triangle E B D = \frac{B D \times E I}{2} = \frac{A C \times E I}{2}$$

$$E A D = \frac{A D \times E G}{2} = \frac{A B \times E F}{2} + \frac{A C \times I H}{2} + \frac{A C \times E I}{2}$$

$$A D \times E G = A B \times E F + A C \times E H.$$

Or, $R \times E G = P \times E F + Q \times E H$.

If the point E be taken within the parallelogram, then $R \times E G = P \times E F - Q \times E H$.

The force P, multiplied by the diſtance E F, is called the moment of the force P relatively to the point E; hence by the preceding propoſition it appears that, according to this definition, the moments of the producing forces are equal to the moment of the reſulting forces; and in caſe of equilibrium, the ſum of the moments of all the forces are equal to nero.

If the point E be taken in the direction of one of the producing forces, as P, then E F = o;

$$R \times E G = Q = E H$$
$$R : Q :: E H : E G.$$

If E be taken in the direction of the reſulting forces E G = o, and $P \times E F = Q \times E H$, hence

$$P : Q :: E H : E F.$$

This propoſition, which is quite independent of any idea of motion, rotation, or force, may be deduced generally, by means of the analytic equations already demonſtrated for finding the reſulting force, from any number of producing forces ſoliciting a point; but the property being entirely geometrical, that form for the demonſtration has been preferred.

ferred. The above propoſition is a very important one in the general equations of equilibrium. The ſame propoſition may be extended to parallel forces, by ſuppoſing the point A to recede to an infinite diſtance by the revolutions of A P, A Q, round any two points M, N; then the figure will take the form as deſcribed in (*fig.* 7). And ſince

$$P \times EF = Q \times EH$$
$$R \times EG = Q \times EH$$
$$P : Q :: EH : EF$$
$$R : Q :: EH : EG$$

Corol. ſince $P : GH :: Q : EF :: R : FH$

$$P + Q : GH + EF :: R : FH$$

And $P + Q = R$.

and $P - Q = R$, when they act in oppoſite directions.

Or the ſame propoſition may be demonſtrated thus, without the neceſſity of conſidering the point as removed to an infinite diſtance.

Let two parallel forces, p and q, (*fig.* 8.) acting in the ſame direction, be applied to the two extremities E, F, of the line E F, to which they are perpendicular; then ſuppoſe two new forces p', q', applied at the extremities E, F, in oppoſite directions; p' being equal to q'. It is evident theſe forces will not tend to alter the ſtate of the ſyſtem, being equal and oppoſite: reſolve p' and p, q' and q, into P and Q, and let theſe forces produced meet in A. Through A draw B C parallel to E F, and A O perpendicular to it. Decompoſe the forces P and Q according to the directions A B, A O, and A C, A O; the firſt will be p' and p, the ſecond q and q', ſince the circumſtances of this are the ſame at A as E and F; the two forces q' and p' deſtroy each other; the reſulting force acting in the direction A O is therefore $p + q$. Since P is the reſulting force of two rectangular forces p and p', the tangent of the angle $PEp' = \frac{p}{p'} = \frac{AO}{EO}$; hence $p' = p \cdot \frac{EO}{AO}$; in the ſame manner $q' = q \cdot \frac{OF}{OA}$; therefore $p \times EO = q \times OF$, which is the known principle of the lever.

If the two parallel forces P and Q are oblique to the line of application E G, and if their reſulting force be R, then draw B D perpendicular to the force, and ſuppoſe B, C, D, the points of application; and ſince $P \times BC = Q \times CD$, and E F and F G are proportional to B C, C D; $P \times EF = Q \times FG$, which ſhews that the preceding propoſition does not require the direction of the forces to be perpendicular to the line of application. Therefore, in general, the reſulting force of two parallel forces is equal to their ſum and parallel to them, and divides the line to which they are applied in two parts, reciprocally proportional to theſe forces.

If $EG = a$, $EF = p$, $FG = q$

$a = p + q$, $R = P + Q$, $Pp = Qq$.

of which ſix quantities, three being given, the remainder may be found.

Let us next conſider the effect of any ſyſtem of parallel forces P′, P″, P‴, acting on different points of any body whatever: let x', y', z', x'', y'', z'', be the reſpective co-ordinates of theſe points to the three rectangular planes; let D, K, (*fig.* 9.) be the points of application of the forces P′, P″, and G that of their reſulting force R, and let a', b', c', be the three co-ordinates of G; then

$$AB = x', \quad BC = y', \quad CD = z'$$
$$AH = x'', \quad HI = y'', \quad IK = z'$$
$$AE = a', \quad EF = b', \quad FG = c'$$

$R' = P' + P''$, and if D K be produced till it meets the plane of xy in L; $R' \times LG = P' \times LD + P'' \times LK$; and ſince L G, L D, L K, are proportional to their projections $R'a' = P'x' + P''x''$, for the ſame reaſon

$R'b' = P'y' + P''y''$, and $R'c' = P'z' + P''z''$.

In which equations great attention muſt be paid to the ſigns which are neceſſarily poſitive; they are ſufficient to give both the magnitude and direction of the reſulting force.

This reſulting force R′ muſt be taken with the next force P‴ to obtain a new force, and this proceſs continued till all the forces are combined; R′ being ſubſtituted for P′ and P″, and combined with P‴, we have

$$R'' = R' + R'', \qquad R''a'' = R'a' + P'''x'''$$
$$R''b'' = R'b' + P'''y''', \quad R''c'' = R'c' + P'''z'''$$

ſubſtituting for R′, R′ a', R′ b', R′ c' their values, the values of R″, R″ a'', R″ b'', R″ c'' are obtained, and finally the reſulting force R; and its direction is obtained in the following equations:

$$R = P' + P'' + \&c.$$
$$Rx = P'x' + P''x'' + \&c.$$
$$Ry = P'y' + P''y'' + \&c.$$
$$Rz = P'z' + P''z'' + \&c.$$

The firſt equation gives the magnitude of the force; the co-ordinates x, y, z, of the point of application, are

$$x = \frac{P'x' + P''x'' + \&c.}{P' + P'' + \&c.}$$
$$y = \frac{P'y' + P''y'' + \&c.}{P' + P'' + \&c.}$$
$$z = \frac{P'z' + P''z'' + \&c.}{P' + P'' + \&c.}$$

Theſe equations being independent of the direction of the forces, it is evident that the point which has x, y, z for its co-ordinates, will remain the ſame, even when the forces take other parallel directions, provided that the points of application remain the ſame; therefore there exiſts a point through which the reſulting force always paſſes, when the forces turn round the point of their application. This point may be termed the *centre of parallel forces*.

It now only remains to inveſtigate the general caſe, where any number of forces are ſuppoſed to act on a body in any directions whatever.

Firſt, let the figure be ſuppoſed a plane, and the forces likewiſe ſituated in the plane of the figure.

Let P′, P″ &c., repreſent the forces; x', y', x'', y'', the co-ordinates of the points on which they act; α', α'', the angles which theſe co-ordinates make with the axis of x. Let P′ be reſolved into two forces X′, Y′, parallel to the axes x, y, and P″ into X″, Y″, &c. then

$P' \cos. \alpha = X'$, $P'' \cos. \alpha'' = X''$, &c.

$P' \sin. \alpha = Y'$, $P'' \sin. \alpha'' = Y''$, &c.

There will therefore be two collections of parallel forces, which may each be compoſed into a ſingle force. Let X be the ſingle reſulting force parallel to the axis x, and b its diſtance from it, Y and a the force and diſtance of the other parallel to the axis y; then

$$X = X' + X'' + \&c; \quad Y = Y' + Y'' + \&c.$$

$Xb = X'y' + X''y'' + \&c$; $Ya = Y'x + Y''x'' + \&c$;

The forces X, Y, may now be combined into a ſingle one, which will be applied in their point of interſection, whoſe co-ordinates are a and b.

As the point of application of R may be taken in any part of its direction, it is neceſſary to determine the equation of the ſtraight line repreſenting this direction, ſince it paſſes

paſſes through two points, whoſe co-ordinates are a, b, its equation is $Y - b = \text{tang. } a\,(x - a)$; or ſince tang. $a = \frac{Y}{X}$, $X\,y - Y\,x = X\,b - Y\,a$, and by ſubſtitution for the values of $X\,b - Y\,a$, $X\,y - Y\,x = X'\,y' - Y'\,x' + X''\,y'' - Y''\,x'' + \&c.$

Here x and y are the co-ordinates of the point of application of the reſulting force $X'\,y' - Y'\,x'$, the difference of the moments of the forces X', Y'; the ſame of the other forces: therefore, if p', p'', r, repreſent the perpendiculars let fall from the origin to the directions of the forces

$$X = X' + X'', \quad Y = Y' + Y''$$
$$R\,r = P'\,p' + P''\,p'' + \&c. \quad . \quad . \quad . \quad . \quad (m)$$

If π repreſent the ſum of the moments, $R \cos. \alpha = X$, $R \text{ ſin. } \alpha = Y$, $R\,r = \pi = X\,\gamma - Y\,x$.

The conditions of equilibrium of this ſyſtem are obtained by ſuppoſing it to exiſt, and then one of the forces P to be removed; the reſulting force R may then be conſidered as $= -P$, and the equation $X\,y - Y\,x = \pi$, ſhould be that of the force P. Hence by ſubſtitution the equations of equilibrium are obtained

$$\left.\begin{array}{l} X' + X'' + \&c. = o \\ Y' + Y'' + \&c. = o \\ P'\,p' + P''\,p'' + \&c. = o \\ \text{or } X'\,Y' - Y'\,x' + X''\,y'' - Y''\,x'' + \&c. = o \end{array}\right\} (n)$$

In the ſame form are the terms of P, &c.

If the ſyſtem be fixed by a point about which it may take a motion of rotation, the equilibrium may ſubſiſt without the forces deſtroying each other, provided the reſulting force paſſes through the fixed point. If this point be the origin of the ordinates, $x = o$, $y = o$, and $\pi = o$; and $P'\,p' + P''\,p'' + \&c. = o$.

If the equilibrium does not ſubſiſt, it may eaſily be eſtabliſhed, by adding a force whoſe intenſity and direction will be found by the above formulæ. It would be only neceſſary to introduce a new force P, which ſatisfies the equation (m); if p be its diſtance from the fixed point, P and p muſt be taken ſuch, that $P\,p + P'\,p' + P''\,p'' = o$, which problem is indeterminate as one of the quantities may be of any value whatever; ſome condition therefore may be added, as for inſtance, that the preſſure on the fixed point may equal in quantity and direction ſome given force, &c.

Let us imagine a ſolid body ſituated in ſpace, the reſpective points of which are ſolicited by any ſyſtem of forces, whoſe intenſity and directions are expreſſed by the ſame ſymbols or notation as before, but ſince the forces are not ſuppoſed to meet in any one point, the poſition of each muſt be determined by that of one of the points of its direction; for inſtance, the point of its application to the ſyſtem; let x', y', z', x'', y'', z'', be the co-ordinates of theſe points of the forces P', P'', &c. Reſolve each force at the point of its application into three others parallel to the axes of the rectangular co-ordinates; let X', Y', Z', be the three reſolved forces of P'; X'', Y'', Z'', thoſe of P'', &c. that is, let

$$P' \cos. \alpha' = X'; \quad P'' \cos. \alpha'' = X''$$
$$P' \cos. \beta' = Y'; \quad P'' \cos. \beta'' = Y''$$
$$P' \cos. \gamma' = Z'; \quad P' \cos. \gamma' = Z'.$$

Let a plane be imagined fixed in the ſolid body, and moveable with it; let this be the plane of $x\,y$, and ſuppoſe each force produced till it meet this plane; the equations of the ſtraight line repreſenting the force P' are $x - x' = A\,(z - z')$; $y - y = B\,(z - z')$; and, as above, $A = \frac{X'}{Z'}$, and $B = \frac{Y'}{Z'}$.

To obtain the point, where the point in which the line in-

terſects the plane of $x\,y$, make $z = o$, which gives for the co-ordinates a', b', of this point

$$a' = \frac{Z'\,x' - X'\,z'}{Z'}, \quad b' = \frac{Z'\,y' - X'\,z'}{Z'}.$$

And by changing the accents, analogous values are obtained for the other forces.

If every force be ſuppoſed to be applied at the point where its direction interſects the plane of $x\,y$, it may be reſolved into two, one in the direction of the plane, and the other parallel to the axis z. Now the equilibrium cannot take place except it ſubſiſt ſeparately in each of theſe collections of forces. The equations which expreſs this ſtate are thus attained.

The parallel forces to z ſhould ſatisfy the three equations

$$P' + P'' + \&c. = o \quad . \quad . \quad . \quad . \quad . \quad . \quad .$$
$$P'\,x' + P''\,x'' + \&c. = \text{tang. } \alpha\,(P'\,z' + P''\,z'' + \&c.)$$
$$P'\,y' + P''\,y'' + \&c. = \text{tang. } \beta\,(P'\,z' + P''\,z'' + \&c.)$$

and as the force Z' is applied to a point, of which a' and b' are the co-ordinates, the moments of Z' are $Z'\,a'$ and $Z'\,b'$, or $Z'\,x' - X'\,z'$, and $Z'\,y' - Y'\,z'$.

In like manner are obtained thoſe of Z''; hence

$$Z' + Z'' + \&c. = o$$
$$Z'\,x' - X'\,z' + Z''\,x'' - X''\,z'' + \&c. = o$$
$$Z'\,y' - Y'\,z' + Z''\,y'' - Y''\,z'' + \&c. = o.$$

The forces ſituated in the plane ſhould alſo ſatisfy the three equations (n) of the laſt problem. To apply them, every force muſt be reſolved into two others, parallel to x and y; P' into X', Y', and P'' into X'', Y'', and a', b', ſubſtituted for x', y', and $a''\,b''$ for x'', y''.

The ſtate of equilibrium, therefore, of a ſolid body, will be expreſſed by ſix equations.

$$\left.\begin{array}{l} X' + X'' + X''' + \&c. = o \\ Y' + Y'' + Y''' + \&c. = o \\ Z' + Z'' + Z''' + \&c. = o \end{array}\right\} (M)$$

$$\left.\begin{array}{l} X'\,y' - Y'\,x' + X''\,y'' - Y''\,x'' + \&c. = o \\ X'\,z' - Z'\,x' + X''\,z'' - Z''\,x'' + \&c. = o \\ Z'\,y' - Y'\,z' + Z''\,y'' - Y''\,z'' + \&c. = o \end{array}\right\} (N)$$

If the ſyſtem contains a fixed point or fixed axis, it may be in equilibrium without the forces deſtroying each other; it would be ſufficient for the reſulting force to be directed to this axis or this point.

If the ſyſtem is retained by a fixed axis, for inſtance that of z, it has no tendency to impreſs any motion on the body, and may therefore be neglected; it is ſufficient that the forces that act in the plane of $x\,y$ be in equilibrium about their fixed origin. And we may conclude that a ſolid body is in equilibrium whenever the two collections of producing forces, which are in planes perpendicular to this axis, have the ſum of their moments equal relatively to two rectangular planes paſſing through this axis.

If the ſyſtem is retained by a ſingle point (the origin of the co-ordinates) the above equations muſt ſubſiſt, but are not ſufficient; the forces parallel to z muſt no longer be neglected, and their reſulting forces muſt paſs through the origin or fixed point.

Of the equations (M), (N), the former are called equations of *tranſlation*; becauſe, when they ſubſiſt, the body has no tendency to take any motion of tranſlation. The latter three are called equations of rotation; becauſe it is neceſſary they ſhould take place, to prevent the body from taking a rotatory motion; and all the ſix muſt ſubſiſt at once, to ſecure a perfect equilibrium. If the equilibrium does not take place, but there is one reſulting force only as R; then if R be reſolved into X Y Z, the ſix equations will ſubſiſt, provided the forces $-X - Y - Z$ are added to the reſt. The three firſt equations give, as in the former problems,

$$R = \sqrt{\left\{ X^2 + Y^2 + Z^2 \right.},$$

$$\text{Cos. } \alpha = \frac{X}{R},\ \text{cos. } \beta = \frac{Y}{R},\ \text{cos. } \gamma = \frac{Z}{R};$$

so that nothing remains but to employ the three equations, N, to determine the value of the co-ordinates x, y, z, and then to determine the point of application of R. Let

$$L = (X' y' - Y' x') + \&c.$$
$$M = (Z' x' - X' z') + \&c.$$
$$N = (Y' z' - Z' y') + \&c.$$

X, Y, Z, L, M, N, will be known quantities, and the equations (N) will give,

$L = Xy - Yx$; $M = Zx - Xz$; $N = Yz - Zy$; by which X, Y, Z are determined, and by multiplying these equations by Z, Y, and X, and adding,

$$LZ + MY + NX = o;$$

without which equation the three preceding equations cannot subsist together: it therefore expresses the conditions of the data of the problem, necessary for all the forces to be reducible into a single one.

Hence it appears that a system of forces in space cannot be generally maintained in equilibrium by a single force. But when the equation $LZ + MY + NX$ subsists, then there will be a single resulting force, whose direction and intensity may be found; and its point of application may be anywhere in the straight line whose equations are $Xy - Yx = L$, &c. In other cases, there will be two resulting forces, which cannot be combined into one.

If the body is fixed either on a centre or an axis, a force must be introduced into the system, which shall satisfy the three equations (M) in the first case, and (N) in the second. The problem will then be indeterminate; and other conditions may be required, such as that a certain pressure shall be produced on a given point or axis, &c. &c.

The pressure which a fixed point or axis sustains from the action of a system is always equal, and in a contrary direction to the force which must be employed to produce equilibrium in the system, in case it was free. The rules, therefore, for the investigation of the pressure on a point or axis, are the same as those for finding the resulting force of a number of producing forces.

The fixed axis of a system of bodies is often sustained on two points, at its extremities, or elsewhere; and it is sometimes required to determine the pressure on these points. Let EF (*fig.* 10.) be the fixed axis; A, B, the points on which it is supported; R M, the resulting force. Then to determine the pressure on A and B, the force R must be resolved into two others applied to the points A, B, according to the rules given above.

In the case of equilibrium about a fixed axis, every force parallel to the axis may be neglected; but to determine the pressure on certain points of this axis, these forces must be taken into consideration. For instance, suppose it were required to determine the pressure which a force R, (*fig.* 11.) parallel to the axis A B, produced on two fixed points, A, B.

Let $AC = BD = r$, $AB = a$; and suppose at the point A, two forces, M, Q, applied in the directions A M, A Q; and at the point B, the force S directed towards B S, so as to produce equilibrium in the system C A B D, then the efforts exercised on A and B will be determined. If the point A be taken as the origin of the co-ordinates x, y; A B for the axis x; A C that of y; the equations of equilibrium become

$$R - M = o;\ S - Q = o;\ Rr - Sa = o.$$

From the first it appears that the body or system is solicited in the direction A B, the same as if the force R acted directly in that line; and the other equations give $S = Q = \frac{Rr}{a}$. Hence, the force R tends to turn the axis on the points A and B, with an equal action in opposite directions.

On the Motion of Bodies directed to Centres of Force.—To solve these problems, we must refer to the general differencial equations of varied motions. These are $\frac{d^2x}{dt^2} = \frac{dv}{dt} = F$; $x = \varphi(t)$; $v = \frac{dx}{dt}$; $F.dx = v\,dv$; where x = space, and t = time.

If a body descend from a state of rest towards a centre of force, if the intensity of this force at a given distance be known, and likewise the law of its variation; then the velocity at any point, and the time of descending through any given portion of the space, may be found by a proper application of the above equations. The artifice consists in obtaining an expression for the accelerating force in terms of x, the space described; which expression being multiplied by dx, the double of its integral will be the square of the velocity, since $F\,dx = v\,dv$. And when the velocity is obtained, it may be substituted in this expression $\frac{dx}{v}$, for v; and the integral of it will be equal to the time employed, since $dt = \frac{dx}{v}$.

Force may become an object of calculation, as the cause of motion, when it is either instantaneous, constant, or variable, according to some given law.

If a force acts on any particle of matter instantaneously, or, if after acting on it a certain time, its action ceases, the motion produced is uniform; and we apprehend that it is of this uniform motion alone that the human intellect can form a very accurate conception. For though no one doubts that we are able to compute, justly and accurately, the effects of forces which produce continued varied motion, yet it is always done by some artifice to assist the imagination, and by resolving this variable motion into a number of elementary partial ones, which are supposed infinite: but being fully aware of the error this artificial method might produce, we endeavour to investigate and assign a limit to this error, which fortunately we are not only able to do, but to correct it entirely, so as to add to our first calculation the advantage of mathematical precision.

Let any person, unacquainted with the fluxional or differential calculus, attempt to solve the easiest of the following problems, and he will be insensibly led to the method of limits. He will first divide the space or the time into ten finite parts, next into one hundred, then one thousand; and finding that the error continually diminishes, he will endeavour to find the law of the series, and to what term it continually approaches as a limit, and which will be the answer to the problem, when, instead of a limited number of finite elements, it is supposed divided into a number of infinitely small ones.

Let C (*fig.* 12) be a centre, toward which bodies are attracted with forces which are inversely proportional to the squares of the distance from C. Let a particle begin to descend from A, by the action of a central force residing in C. It is required to ascertain the velocity acquired at any given point O of its descent.

Let f represent some standard force, as that of gravity, and G be the distance at which C exerts a force equal to f. Let $GC = r$. $AC = a$, $AO = x$.

Then F (the force at O) : f (force at G) :: CG^2 : CO^2
$r^2 : (a-x)^2$.

Therefore, $F = \frac{f \cdot r^2}{(a-x)^2}$; but since $F\,dx = v\,dv$,

dx

$dx \cdot \frac{f \cdot r^2}{(a-x)^2} = v\,dv$; and $\frac{v^2}{2} = \int \cdot \frac{f \cdot r^2}{(a-x)^2} + C = \frac{f r^2}{a-x} + C$; and ſince when $x = o$. $v = o$, $C = \frac{f r^2}{a}$, and $v^2 = 2\left(\frac{f r^2}{a-x} - \frac{f r^2}{a}\right) = \frac{2 f r^2 x}{a \cdot a - x}$, and $v = \sqrt{\frac{2 f r^2}{a}} \times \sqrt{\frac{x}{a-x}}$.

To obtain the time t, we muſt refer to the general equation $dt = \frac{dx}{v}$, and ſubſtitute the value of v, above found, in the expreſſion $\frac{dx}{v} = \frac{dx}{\sqrt{\frac{2 f r^2}{a} \cdot \frac{x}{a-x}}} = \sqrt{\left(\frac{a}{2 f r^2} \cdot \frac{a-x}{x}\right)} \cdot dx = dt \cdot t = \int \sqrt{\left(\frac{a}{2 f r^2} \cdot \frac{a-x}{x}\right)} = \sqrt{\frac{a}{2 f r^2}} \cdot \sqrt{\frac{a-x}{x}}$; and multiplying the latter fraction by $a - x = \sqrt{\frac{a}{2 f r}} \cdot \frac{a-x}{\sqrt{a x - x^2}}$.

To integrate this fraction, ſuppoſe $x = \frac{1}{2}a - z$, the integral is then that of the fraction $\frac{-\frac{1}{2}a - z}{\sqrt{\frac{1}{4}(a^2 - z^2)}} - dx$, which may be divided into $\int \frac{-z\,dx}{\sqrt{\frac{1}{4}(a^2 - z^2)}} = \sqrt{(\frac{1}{4}a^2 - z^2)}$, and $\int \frac{-\frac{1}{2}a\,dz}{\sqrt{\frac{1}{4}(a^2 - z^2)}} = \frac{1}{2}a$. arc $\left(\text{cos.} = \frac{2z}{a}\right)$. The conſtant quantity $C = o$, becauſe when $x = o$, $t = o$, $z = \frac{1}{2}a$; ſubſtituting for z its value $\frac{1}{2}a - x$; $t = \sqrt{\frac{a}{2m}}\left\{\sqrt{a x - x^2} + \frac{1}{2}a \times \text{arc}\left(\text{cos.} = \frac{a - 2x}{a}\right)\right\}$.

For the method of finding this fluent geometrically, ſee Atwood's treatiſe on Rectilinear Motion, p. 66.

Example.—Let a body begin to deſcend from a ſtate of reſt at A (*fig.* 13.) towards C. Let the force be ſuch as, if continued uniform, would cauſe A to deſcend one foot in one ſecond, required the velocity when it arrives at O $= \frac{1}{2}$ A C.

F (force at O) : f (force at A $= 1$) :: A C^2 : C O^2 :: $a^2 : (a-x)^2$

$$F = \frac{a^2}{(a-x)^2}$$

$$F \cdot dx = \frac{a^2}{(a-x)^2} \cdot dx = v\,dv$$

$$\frac{v^2}{2} = \frac{a^2}{a-x} + C; \text{ when } x = o, v = o$$

$$\frac{v^2}{2} = \frac{a^2}{a-x} - a = (\text{when } x = \tfrac{1}{2}a)\ \frac{a^2}{\frac{1}{2}a} - a = a$$

$v^2 = 2a$, and $v = \sqrt{2a}$.

Suppoſe a material particle at A (*fig.* 14.) to be ſolicited by two forces, one producing motion from A towards B, uniformly accelerated; the other tending to move it towards D, and acting in an inverſe ratio of the diſtance of the particle A from B; required the circumſtances of the motion which will take place from the action of theſe forces.

Let A B $= a$, A N $= s =$ the ſpace deſcribed at the end of the time t. Let γ be the accelerating force of repulſion from A towards D, and g the conſtant force which acts in the contrary direction N B. Let m be the value of the force γ, at any diſtance B aſſumed as unity. Then by the nature of the queſtion $\frac{\text{N B}}{1}$, or $\frac{a+s}{1} = \frac{m}{\gamma}$, and $\gamma = \frac{m}{a+s}$. The force f, which acts on the particle at the end of the time t, is the difference of the two forces, or $f = \gamma - g$. Hence $f = \frac{m}{a+s} - g$; $f\,d\,s = v\,d\,v$; $d\,s = v\,d\,t$: by means of theſe equations, two out of the four quantities s, t, v, f, may be eliminated.

The firſt and ſecond equations give $v\,d\,v = \left(\frac{m}{a+e} - g\right) d\,s$; and by integration $\frac{v^2}{2} = m$. hyp. log. $(a+e) - g\,s + C$; at the point A $v = o$, $s = o$; hence $C = -m$. hyp. log. a.

Therefore $v = \pm \sqrt{\left\{2m \times \text{hyp. log.}\left(\frac{a+s}{a}\right) - 2g\,s\right\}}$

To obtain the relation between s and t, the value of v thus found, muſt be ſubſtituted in the differential equation $v = \frac{ds}{dt}$, and the integral found as in the former example.

This problem relates to the caſe of a piſton moving in a cylinder, containing in the part A B an elaſtic fluid. The piſton being acted on by the action of gravity, and likewiſe by the action of the external air, will tend to deſcend with a conſtant force g, and the action γ of the elaſtic fluid will be the leſs, as the ſpace containing it is greater, or as the piſton is farther from B.

To obtain the maximum of velocity, $d\,v$ muſt $= o$, or $f = \frac{m}{a+s} - g = o$, and $a + s = \frac{m}{g} =$ B N, beyond which point v decreaſes, the motion is retarded, and ceaſes when m . hyp. log. $\left(\frac{a+s}{a}\right) = g\,s$, when it is again accelerated, and but for the effect of friction the body would thus oſcillate for ever.

We are next to inveſtigate a general formula for curvilinear motion, and to conſider the method of its application.

When a body deſcribes a curve in conſequence of the action of certain forces, we may, in imagination, reſolve this curve into an indefinite number of elementary ſpaces, and ſuppoſe each to be the ſide of an infinitely ſmall polygon, ſo that the body changes at every inſtant the direction of its motion, which is always that of the tangent or prolongation of the ſide of the ſmall polygon. To eſtimate the velocity at any moment, we may conceive the forces to ceaſe to act in the ſame manner as in the caſe of rectilinear motion, and then the velocity v may be repreſented by $\frac{ds}{dt}$.

Whatever be the forces which act on the body, they may always be resolved into three, which are parallel to three rectangular co-ordinates; it is evident that each of the producing forces will have an effect independent of the two others, and consequently we may apply to each the theorems established for rectilinear motion; it is thus that we learn the nature of the motion, and determine the trajectory which the body describes, when the intensity and direction of the forces are given. Curvilinear motion is thus reduced to two or three rectilinear motions, according as the curve is of the single or double curvature.

When the trajectory lies in the same plane, the motion may be represented by two equations, $x = \varphi(t)$; $y = f(t)$: by eliminating t, a relation is obtained between x and y, which will be the equation of the curve described. If the curve be of double curvature, the motion will be represented by three equations, $x = \varphi(t)$, $y = f(t)$, $z = \downarrow(t)$; and by eliminating t, two equations will be obtained in terms of x, y, and z, which will be those of double curvature described by the body. The equations $x = \varphi(t)$, $y = f(t)$, $z = \downarrow(t)$.

Let P', P'', be constant forces, which act on the material particle M, at the end of the time t. Let α', α''; β', β''; γ', γ''; be the angles formed by their directions with the respective axes of x, y, z. Let each force be resolved into three others parallel to these respective axes, namely, X, Y, Z, then each of these forces will impress on the body an elementary impulsion, each in its own direction. Hence these equations;

$$\begin{aligned} X &= P' \cos.\ \alpha' + P'' \cos.\ \alpha'' + \&c. \\ Y &= P' \cos.\ \beta' + P'' \cos.\ \beta'' + \&c. \\ Z &= P' \cos.\ \gamma' + P'' \cos.\ \gamma'' + \&c. \end{aligned}$$

At the end of the time t, the point M, in that point of its trajectory which has for its co-ordinates x, y, z, will have in the direction of x a velocity $= \frac{dx}{dt}$, so that in this point we may conceive the body in repose, and receiving in the direction of the axis x an impulsion producing the velocity $\frac{dx}{dt}$; this velocity should increase during the time dt, by a quantity $= d\left(\frac{dx}{dt}\right)$, by the effect of the constant forces P, P'', &c. so as to become $= \frac{dx}{dt} + d\left(\frac{dx}{dt}\right)$. But, as we have already seen, the velocity communicated in the direction of the axis x is equal $\frac{dx}{dt} + X\,dt$; and as the effects of the other rectangular forces are independent, the forces X, Z, do not change this. Hence the velocities $X\,dt$, $d\left(\frac{dx}{dt}\right)$ are equal. Reasoning in the same manner as to the other forces, we have the following equations.

$$\left.\begin{aligned} X\,dt &= d\left(\frac{du}{dt}\right) \\ Y\,dt &= d\left(\frac{dy}{dt}\right) \\ Z\,dt &= d\left(\frac{dz}{dt}\right) \end{aligned}\right\} (A')$$

Or taking dt constant,

$$\left.\begin{aligned} X &= \frac{d^2x}{dt} \\ Y &= \frac{d^2y}{dt} \\ Z &= \frac{d^2z}{dt} \end{aligned}\right\} (B')$$

which are the general formulæ of motion for a body moving in free space.

These equations are sufficient to investigate all the circumstances of the motion of a material point, that is, to assign its velocity and situation in its trajectory at any given instant. Suppose the forces to act in some plane, *viz.* that of x and y, X and Y being given either constant or variable, we have then only to eliminate t, the time from the two equations $X = \frac{d^2x}{dt^2}$, $Y = \frac{d^2y}{dt^2}$. This being effected, and the integrations made, an equation is obtained between x and y; similar relations may be obtained between x and t, and y and t, then $\frac{dx}{dt}$, $\frac{dy}{dt}$ will give the velocities in the directions of the axes of x and y; whence the real velocity may be concluded, which will be $v = \frac{ds}{dt} = \sqrt{\left\{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2\right\}}$.

A formula, more useful on many occasions, may be thus obtained.

In the equations

$$X = \frac{d^2x}{dt^2};\quad Y = \frac{d^2y}{dt^2};\quad Z = \frac{d^2z}{dt^2}$$

Multiply by dx, dy, dz, as follows:

$$X\,dx + Y\,dy + Z\,dz = \frac{dx\,d^2x + dy\,d^2y + dz\,d^2z}{dt^2};$$

but the numerator of the second member of this equation is the differential of $\frac{1}{2}(dx^2 + dy^2 + dz^2)$, or of $\frac{1}{2}ds^2$; therefore, by taking the integrals, we have $\frac{ds^2}{dt^2} = v^2 = C + 2\int(X\,dx + Y\,dy + Z\,dz)$. This equation, which is similar to that we have already used in the case of rectilinear motion, cannot give an exact solution, except $X\,dx + Y\,dy + Z\,dz$ be an exact differential; or, to use the language of fluxions, except its exact fluent can be found.

If, therefore, X, Y, Z, be functions of x, y, z, the following conditions should subsist, $\frac{dX}{dy} = \frac{dY}{dx}$, $\frac{dX}{dz} = \frac{dZ}{dx}$, $\frac{dY}{dz} = \frac{dZ}{dy}$, and $v^2 = 2\varphi + C$.

The constant quantity C depends on the initial velocity, or on the velocity at some given instant. This last equation comprehends the principle of the "conservatio virium vivarum."

This proposition is in fact the same as the 39th prop. of the first book of Newton's Principia. The reader will find a very ample geometrical demonstration, accompanied with many valuable remarks on these theorems, in Dr. Robinson's Mechanical Philosophy, and in the Supplement to the Encyclop. Britan.

One of the most simple examples of the application of these

theſe equations, is the motion of a projectile in an unreſiſting medium. Let the velocity of the material point M (*fig.* 15.) = V in the direction of the angle θ, with the axis of x; let it be propoſed to determine the curve it deſcribes. Let the axis of y be vertical, as there is no other force but that of gravity: $X = o$; $Z = o$; $Y = -g$; therefore $\frac{d^2x}{dt^2} = o$, $\frac{d^2z}{dt^2} = o$, $\frac{d^2y}{dt^2} = -g$; and by integration

$$\frac{dx}{dt} = c; \frac{dz}{dt} = c''; \frac{dy}{dt} = c' - gt.$$

The firſt of theſe equations, divided by the ſecond, gives by integration

$$c''x = cz$$

equation to a ſtraight line, which ſhews that the projection of the trajectory upon the horizontal plane of xy is a ſtraight line, and that the curve is in a vertical plane, paſſing through the axis of y.

The equations $\frac{dx}{dt} = c$, $\frac{dy}{dt} = c' - gt$, by integration give $x = ct$; $y = c't - \frac{1}{2}gt^2$.

No conſtant quantities need be added ſince when $t = o$, $x = o$, $y = o$. To determine the other two conſtant quantities, c and c', at the commencement of motion, ſince $\frac{dx}{dt}$, $\frac{dy}{dt}$, are the velocities at every inſtant, if the velocity V is vertical, when $t = o$, $\frac{dx}{dt} = o$, and $\frac{dy}{dt} = V$, hence $c = o$, $c' = V$. But when the force producing the velocity V is in the direction of the angle θ, with the axis of x, then when $t = o$, $c = V$, cos. θ and $c' = V$ ſin. θ.

Of the expreſſions for x and y, one is the equation of uniform motion, the other of uniformly varied motion; eliminating t from theſe equations, we find $y = \frac{c'}{c}x - \frac{gx^2}{2c^2}$; ſubſtituting for c and c' their trigonometrical values, the equation to the trajectory

$$y = x \text{ . tang. } \theta - \frac{gx^2}{2V^2 \text{ . cos.}^2\theta}.$$

For V ſubſtitute its value $2gh$, (h being the height due to the velocity V,) and

$$y = x \text{ . tang. } \theta - \frac{x^2}{4h \text{ . cos.}^2\theta}$$

equation to a parabola.

In the ſolution of theſe problems we are to obſerve, that when the nature of the curve is required, it is to be found by determining the relation between x and y, and by combining the differential equations with ſome value of v or t, given by the nature of the problem. On the other hand, when the curve is known, from a given relation between x and y, then the values of v and t are to be determined, by combining the ſame general differential equations with the element of the curve, which repreſents the element of the ſpace, and which is known in terms of x or y by the equation to the curve.

If, in the above problem, the projectile be ſuppoſed to move in a medium, the law of whoſe reſiſtance is known, the inveſtigation of the curve becomes much more difficult. The expreſſions for the forces X, Y, Z, will no longer be of the ſimple form, as in our example; the term t will be more difficult to eliminate, and the ſubſequent integrations infinitely more complex: but the general principle will remain preciſely the ſame. See PROJECTILE.

The ſame principles apply to the motion of bodies in trajectories; the particular caſes of this application will be given under TRAJECTORY, the general nature of the method being as follows.

General theory of the trajectories deſcribed by bodies acted on by centripetal forces.—Suppoſe a material particle projected in any direction, and continually drawn towards a given point by a force varying as ſome function of the diſtance, and whoſe intenſity is likewiſe known at ſome given diſtance: from theſe data we are to inveſtigate the principle by which the curve may be determined.

Let three rectangular co-ordinates be drawn through the centre of force; and let P repreſent the abſolute intenſity of the force at a given inſtant; the radius vector drawn from the centre of force to the point M, in which the body is at that inſtant, makes with each axis a certain angle; the coſines of theſe angles are $\frac{x}{r}$, $\frac{y}{r}$, $\frac{z}{r}$; the forces, therefore, that reſult from the reſolution of the force P, and which are equivalent to it, are $\frac{Px}{r}$, $\frac{Py}{r}$, $\frac{Pz}{r}$.

If, therefore, the element dt be ſuppoſed conſtant, then, by the preceding formulæ, (ſince the forces tend to diminiſh the co-ordinates,)

$$\frac{d^2x}{dt^2} = -\frac{Px}{r}; \frac{d^2y}{dt^2} = -\frac{Py}{r}; \frac{d^2z}{dt^2} = -\frac{Pz}{r} \quad (1)$$

To integrate theſe equations, multiply the firſt by y, the ſecond by x, and ſubtract the firſt product from the ſecond: then

$$\frac{x\,d^2y - y\,d^2x}{dt^2} = o;$$

and

$$\begin{aligned} x\,dy - y\,dx &= c\,dt \\ z\,dx - x\,dz &= c'\,dt \\ y\,dz - z\,dy &= c''\,dt. \end{aligned}$$

Multiply theſe equations by x, y, z, reſpectively, and add, then $c''x + c'y + c = o$, which equation belongs to the trajectory, and indicates that this curve is a plane paſſing through the centre of force. Therefore, in the ſolution of the problem, we may conſider only the two axes of x and y. Let F D M (*fig.* 16.) be the curve; M the point in which the moving body is found at the end of the time t; A the centre of the forces A P = x, P M = y, A M = r. The angle M A $x = u$, the right-angled triangle for the tranſformation of its ordinates into polar co-ordinates, (ſee *Analytic* GEOMETRY,) gives

$$\left.\begin{aligned} r^2 = x^2 + y^2;\ x = r \text{ cos. } u;\ y = r \text{ ſin. } u \\ dx = -r \text{ ſin. } u\,du + \text{cos. } u\,dr \\ dy = r \text{ cos. } u\,du + \text{ſin. } u\,dr \end{aligned}\right\}$$

See alſo *Analytic* FUNCTION, where theſe differential equations are explained.

Therefore, $x\,dy - y\,dx = r^2\,du$;

and $r^2\,du = c\,dt$.

But $\int . r^2 . du$, or $\int . (x\,dy - y\,dx)$ is the double of the area M A H contained by the two radii vectores M A, A H, the poſition of one of which is fixed: therefore, this area $= \frac{1}{2}ct +$ A, taking the radius A H as fixed and belonging to M, when $t = o$.

Hence it appears, that whatever be the central force, the area deſcribed will always be proportional to the time.

By equation (1) $\frac{d^2x}{dt^2} = -\frac{Px}{r}$,

$$\frac{d^2y}{dt^2} = -\frac{Py}{r}$$

multiply by dx, dy respectively, and add: and then since $x\,dx + y\,dy = r\,dr$

$$\frac{dx\,d^2x + dy\,d^2y}{dt^2} = -P\,dr.$$

But as the intenſity of the force P is ſuppoſed to vary by hypotheſis, as ſome function of the diſtance r, the integral of $P\,dr$ may be found.

Suppoſe $\int.(P\,dr) = \varphi + C$, then

$$\frac{dx^2 + dy^2}{dt^2} = -2(\varphi + C) = v^2.$$

This equation contains the principle of the vis viva; it is in ſubſtance the ſame as the 40th Prop. Sect. VIII. of Newton's Principia, from which it is inferred, that if two bodies have at any one diſtance the ſame velocity, when acted on by any centripetal force, they ſhall always have the ſame velocity at any other equal diſtances.

By the transformation of the co-ordinates we obtain theſe equations,

$$r^2\,du = c\,dt,\quad dr^2 + r^2\,du^2 = -2(\varphi + C)\,dt^2,$$

and by eliminating dt, the differential equation of the trajectory becomes

$$du = \frac{c\,dr}{r\sqrt{\{-r^2(\varphi + C) - c^2}},$$

the integration of which quantity gives the curve required; but this can only be effected in particular caſes.

This is the celebrated inverſe problem of centripetal forces, and is the 42d Prop. of the 1ſt Book of Newton's Principia. A geometrical ſolution, with many illuſtrations, is given by Dr. Robiſon, in the article *Dynamics*, Sup. Encyclop. Britan.

Of Forces which act on a body conſtrained to move on a given ſurface.—Let a material particle deſcend from the point B, (*fig.* 17.) and deſcribe the curvilinear ſpace B M, arriving at M at the end of the time t: let A x be the horizontal, A y the vertical axis; ſo that A P $= x$, P M $= y$, B M $= s$: let B C $= k$. The velocity v, in the direction of the element of the curve, is $v = \frac{ds}{dt}$, and the augmentation by the force of gravity is dv in the time dt; but this force tends to communicate the velocity $g\,dt$ in the element of time dt, in the direction M G; let this velocity be decompoſed into two, one in the direction of the normal, and which is evidently deſtroyed by the reſiſtance of the curve; and the other in the direction of the tangent M H $= g\,dt \cdot \frac{dy}{ds}$, ſince $\frac{dy}{ds}$ is the coſine of the angle formed by the tangent T M with the axis of y. Therefore the augmentation of velocity is $dv = g\,dt \cdot \frac{dy}{ds}$; hence $v\,dv = g\,dy$, and by integration $v^2 = 2g(\gamma + C)$. Now at the point B, $\gamma = k$, where the velocity is either zero, or ſuch as is due to ſome given height h, according as the particle had or had not ſome initial velocity; therefore, either $v = 0$ or $v^2 = 2gh$, when $\gamma = k$; hence $C = -k$ or $h - k$. Therefore $v^2 = 2g(y - k)$, or $v^2 = 2g(\gamma + h - k)$.)

In the firſt caſe $v^2 = 2g \times$ M I; therefore, a gravitating particle has the ſame velocity in the direction of the tangent at any part of the curve, as if it had fallen freely from the ſame height, and that whatever be the nature of the curve.

From the above equations we obtain

$$v = \sqrt{\{2g(\gamma - k)\}} \text{ and } \frac{ds}{dt} = \sqrt{\{2g(\gamma - k)}, \text{ and}$$

$$dt = \frac{ds}{\sqrt{\{2g(\gamma - k)}}.$$

From the equation of the curve ds will be known in terms of y and dy, and t will then be obtained by integration.

The caſe of the ſimple pendulum may be taken as an eaſy example of the application of this method; a more complete inveſtigation will be reſerved for its proper place under the article Pendulum.

General theory of the Pendulum.—The equations are $\frac{d^2s}{dt^2} = \frac{dv}{dt} = \varphi$; φ being the conſtant force eſtimated in the direction of the tangent of the curve; s the arc deſcribed at the end of the time t; and $v = \frac{ds}{dt}$ = the velocity acquired. Let g be the force of gravity acting on the material point M, ſuſpended at the extremity of the line C M, ſuppoſed without weight and inflexible, C the point of ſuſpenſion, A P $= x$ the vertical abſciſſa, P M $= y$ the ordinate of the centre of oſcillation, A C $= a$ the length of the pendulum, A D $= b$ the verſed ſine of the arc B A B (*fig.* 18.); B the point of departure, s the arc A M, and v the velocity acquired in the point M at the end of the time t.

The velocity v, due to the height D P $= b - x$, is

$$v = \frac{ds}{dt} = \sqrt{2g(b - x)};$$

but the arc decreaſing as the time t increaſes,

$$dt = \frac{-ds}{\sqrt{2g(b - x)}};$$

but ds muſt be expreſſed in terms of dx, in order to effect the neceſſary integration. The ſquare of the element of the arc being expreſſed by $ds^2 = dx^2 + dy^2$,

$$ds = dx\sqrt{1 + \left(\frac{dy}{dx}\right)^2};$$

the equation to the circle being

$$x^2 + y^2 - 2ax = 0,$$

$$\text{and } ds = \frac{a\,dx}{y} = \frac{a\,dx}{\sqrt{2ax - x^2}},$$

we obtain $dt = \frac{-a\,dx}{\sqrt{2g(bx - x^2)(2a - x)}}$.

The determination of the time therefore depends on the integration of the above expreſſion, which we ſhall not enter into at preſent. This integration effected, gives

$$t = \tfrac{1}{2}\sqrt{\left(\frac{a}{g}\right)} \cdot \left\{1 + (\tfrac{1}{2})^2\frac{b}{2a} + \left(\frac{1\cdot 3}{2\cdot 4}\right)^2\frac{b^2}{2^2a^2} + \left(\frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\right)^2\frac{b^3}{2^3a^3} + \&c.\right\} \text{ arc } \left(\cos. = \frac{2x - b}{b}\right).$$

At the limit $x = b$, likewiſe $t = 0$, and when $x = a$ arc $\left(\cos. = \frac{2x - b}{b}\right) = \pi$ or 3π, 5π, &c.; π being the ſemi-circumference whoſe rad. $= 1$. Subſtituting T for the value of t reſulting from the definite integral,

T =

$$T = \tfrac{1}{2}\sqrt{\left(\frac{a}{g}\right)}\cdot\left\{1 + \left(\tfrac{1}{2}\right)^2\frac{b}{2a} + \left(\frac{1\cdot 3}{2\cdot 4}\right)^2\frac{b^2}{2^2a^2} + \left(\frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\right)^2\frac{b^3}{2^3a^3} + \&c.\right\}\pi.$$

When b or the arc of oſcillation is very ſmall, b may be neglected, and the whole oſcillation 2 T becomes $2T = \pi\sqrt{\frac{a}{g}}$. See PENDULUM; and for the curve of quickeſt deſcent, ſee CYCLOID and *Analytic* FUNCTION. For the motion on an inclined plane, which is a more ſimple caſe of the ſame kind; ſee INCLINED *Plane*.

In the above examples the motion has been ſuppoſed to ariſe from the action of gravity alone, but the theory may be generalized and extended to any forces whatever.

A body cannot be conſtrained to move in a curve ſurface without exerting a re-action on the curve, which will always be perpendicular to the ſurface. Inſtead of this re-action, let us ſuppoſe a normal force N, whoſe intenſity and direction will continually vary, but will always be equal and oppoſite to the preſſure; let this force be included with the others, and with them finally reduced to two, X and Y; the moving particle or body will then be in the ſame ſtate as if free, and will deſcribe a trajectory ſuited to the action of theſe forces. Let B M Z (*fig.* 19.) be the curve; X, Y, the forces parallel to the axes A x, A y; M the place of the body at the end of the time t; B M $= s$, A P $= x$, P M $= y$, and N equal to the normal force expreſſing the reaction of the curve: $\frac{dy}{ds}$, $\frac{dx}{ds}$, are the coſines of the angles which the normal makes with the axes x and y, therefore the producing forces equivalent to N in the direction of theſe axes are $-N\frac{dy}{ds}$, and $N\frac{dx}{ds}$; the firſt is negative, becauſe it tends to diminiſh the value of x. The body may therefore be conſidered as free and ſolicited by the forces $X - N\frac{dy}{ds}$, and $Y + N\frac{dx}{ds}$, and the equations of varied motion already given become

$$\left.\begin{aligned} &\frac{d^2x}{dt^2} = X - N\frac{dy}{ds};\ \frac{d^2y}{dt^2} = Y + N\frac{dx}{ds} \\ &d\left(\frac{dx}{dt}\right) = \left(X - N\frac{dy}{ds}\right)dt;\ d\left(\frac{dy}{dt}\right) = \left(Y + N\frac{dx}{ds}\right)dt \end{aligned}\right\}(m)$$

By combining with theſe the equation of the curve, three relations are obtained between the four variable quantities x, y, t, and N, ſo that by integration and elimination equations are obtained between any two of them.

To find the velocity, multiply the firſt of the above equations by dx, and the ſecond by dy, and add them, the terms containing N will then diſappear, and an equation, ſimilar to thoſe already found, will be obtained, *viz.*

$$v^2 = C + 2\int(X\,dx + Y\,dy) \text{ or}$$
$$v^2 = C + 2\varphi,$$

which contains the principle of the *vis viva* as was obſerved above. See MECHANICS.

The value of C depends on the values of v and φ at ſome given inſtant; let v' and φ' be theſe values at that inſtant, then making $v = v'$, and $\varphi = \varphi'$, $A = v'^2 - 2\varphi'$, and v at the ſecond point is given ſince $v^2 = v'^2 + 2(\varphi - \varphi')$, now the value of φ and φ' depend on the co-ordinates of the extreme points, ſo that the velocity at the ſecond inſtant is given by the velocity at the firſt, and by the poſition of theſe points; we may hence infer, that the velocity does not depend on the form of the curve deſcribed, but only on the reſpective poſitions of the point of departure, and of the point at which the body arrives; ſo that had the body been conſtrained to move in any other curve paſſing through theſe points, the velocity acquired at the ſecond point will be the ſame. It appears likewiſe from this, that the preſſure againſt a curve ſurface does not diminiſh or change the velocity.

If the body is not ſolicited by the continual action of any force, but ariſes only from ſome primitive impulſion, its velocity will be conſtant, for when $X = o$, $Y = o$, $C = v^2$.

The caſe of gravity is included in this reſult; for if $X = o$, $Y = g$, and $v^2 = C + 2g\gamma$, for if B be the point of departure from a ſtate of reſt, (*fig.* 20.) then making $Y = BC = k$ as before, $v = o$ and $C = -2gk$ and $v^2 = 2g(y - k) = 2g \times MI$. The ſame as found above.

The preſſure which the body exerts on the curve is equal and oppoſite to the force N; to determine it let dt be taken as conſtant, and dx as variable, then the preceding equations (m) become

$$-\frac{dx}{dt}\cdot d^2t = X - N\cdot\frac{dy}{ds}$$
$$\frac{dt\cdot d^2y - dy\cdot d^2t}{dt^2} = Y + N\frac{dx}{ds}.$$

To exterminate d^2t, multiply the firſt by dy, the ſecond by ds, and ſubtract, then ſince $ds^2 = dx^2 + dy^2$ $\frac{dx\,d^2y}{dt^2} = Y\,dx - X\,dy + N\left(\frac{dx^2 + dy^2}{ds}\right) = Y\,dx - X\,dy + N\,ds$. The value of N might be determined in terms of X and Y, and of the differentials depending on the nature of the curve, but the formula may be rendered more ſimple, by introducing the radius of curvature R, which is always equal to $\frac{ds^3}{dx\,d^2y}$. By ſubſtituting therefore for $dx\,d^2y$ its value $\frac{ds^3}{R}$, we obtain this equation;

$$N = \frac{v^2}{R} + \frac{X\,dy - Y\,dx}{ds}. \quad (n)$$

When, therefore, a material point is conſtrained to move on a curve ſurface, whoſe equation $y = \varphi x$ is given, we muſt to the general equation

$$\frac{ds^2}{dt^2} = v^2 = C + 2\int(X\,dx + Y\,dy + Z\,dz)$$

and for X, Y, y and dy, ſubſtitute their values in terms of x; and deduce the value of v; with which quantity, by a ſimilar ſubſtitution in the preceding formula (n), we ſhall obtain by integration the velocity in the direction of every axis at the end of a given time t.

It appears by equation (n), that the preſſure $-N$, which the body exerts againſt the curve it deſcribes, is compoſed of two parts; one entirely depending on the velocity of the body, the other on the accelerating forces by which it is ſolicited; the other is the ſum of the forces $-X\frac{dy}{ds}$, $Y\frac{dx}{ds}$, which combined, produce the accelerating forces in the direction of the normal. If the body is not ſubject to the action of any accelerating force, its motion can only ariſe from an original impulſion, and will therefore be uniform; the preſſure therefore will be expreſſed by the firſt

part of the equation, and if h expreſs the height due to the velocity v,

$$N = \frac{v^2}{R} = \frac{2gh}{R}$$

N then becomes what is called the centrifugal force; it is that part of the preſſure which ariſes from the velocity alone: in general this force varies at every inſtant, but becomes conſtant when the body deſcribes the circumference of a circle, ſince v and R are in that caſe conſtant.

On the motion of a point reſtrained to move on a curve ſurface. Let the differential equation to the ſurface be

$$dz = p\,dx + q\,dy,$$

p and q being the coefficients of the partial differences of z taken reſpectively relative to x and y, (ſee *Analytic* FUNCTION.)

(Let $M = \sqrt{1 + p^2 + q^2}$). Now the angles which the normal to a curve ſurface makes with the axes of x, y, and z, are $\frac{p}{M}$, $\frac{q}{M}$, $\frac{1}{M}$, (ſee *Analytic* GEOMETRY.) Conceive a force N to be added in the direction of the normal, equal and contrary to the preſſure, its producing forces in the direction of the axes will be $-\frac{pN}{M} - \frac{qN}{M}$ and $\frac{N}{M}$; the two firſt terms are negative, becauſe they tend to diminiſh the co-ordinates x and y, ſuppoſing the convexity of the ſurface to be towards the planes xz, and yz; the point may now be conſidered as free, and ſolicited by the three accelerating forces $X - \frac{Np}{M}$, $Y - \frac{Nq}{M}$, and $Z + \frac{N}{M}$. Inſtead of the former equations (A′) (B′) of curvilinear motion, we have (ſuppoſing dt conſtant,)

$$\frac{d^2x}{dt^2} = X - \frac{Np}{M}$$

$$\frac{d^2y}{dt^2} = Y - \frac{Nq}{M}$$

$$\frac{d^2z}{dt^2} = Z + \frac{N}{M}.$$

Of the meaſure of Force.—Early in the laſt century a controverſy was carried on relative to this ſubject, with a keenneſs which was not perfectly conſiſtent with the dignity of true philoſophy. Now that all difference of opinion has nearly or entirely ceaſed, we are enabled to take an impartial review of the ſubject, and it appears that the queſtion turned much on a diſpute about the meaning of words, each party admitting all the facts produced by the other, and each party ſolving all problems relating to the ſubject by the ſame means, and obtaining the ſame reſult. Newton had defined the meaſure of force to be the maſs of a body multiplied into its velocity, and for the purpoſes of thoſe philoſophical inveſtigations in which Newton was engaged, this definition was both convenient, and at the ſame time mathematically juſt; but there is another point of view, in which it appears that the effects of force may, without any impropriety, be ſaid to depend on the maſs multiplied into the ſquare of the velocity; it is this product which has been called the *vis viva*, and which has been ſo repeatedly mentioned in the preceding pages. Bernouilli and Leibnitz conſidered the *vis viva* as the true and univerſal meaſure of force, in oppoſition to the Newtonian definition. It is now generally admitted that theſe great mathematicians were led into a miſtake, by not ſufficiently taking into conſideration all the circumſtances of the queſtion of diſpute. But it muſt be admitted that the meaſure adopted by them, and called the *vis viva*, merits attention, and in all caſes of practical machinery it is often the moſt accurate, and always the moſt uſeful; and does not imply the leaſt contradiction to the Newtonian definition, only the force thus meaſured ſhould be diſtinguiſhed by ſome peculiar name, as for example the *vis mechanica*, the Newtonian meaſure being applied to the *vis motrix*, as ſuggeſted by Mr. Wollaſton in the Bakerian Lecture for the year (1805), from which the following is an extract.

Let a ball of clay, or any other ſoft and wholly inelaſtic ſubſtance, be ſuſpended at reſt, but free to move in any direction with the ſlighteſt impulſe; and let there be two pegs, ſimilar and equal in every reſpect, be inſerted into its two oppoſite ſides; let there be alſo two other bodies, A and B, of any magnitude, which are to each other in the proportion of two to one, ſuſpended in ſuch a poſition, that when perfectly at reſt, they ſhall be in contact with the extremities of the oppoſite pegs, without preſſing on them. Now if theſe bodies were made to ſwing, with motions ſo adapted, that in falling from heights in the proportion of one to four they might ſtrike at the ſame inſtant againſt the pegs oppoſite to them, the ball of clay would not be moved from its place to either ſide; nevertheleſs the peg impelled by the ſmaller body B, which has the double velocity, will be found to have penetrated twice as far as the peg impelled by A.

It is unneceſſary to make the experiment preciſely as here ſtated, ſince the reſults are admitted as facts by both parties, but upon theſe facts they reaſon differently.

One ſide, obſerving that the ball of clay remains unmoved, conſiders the proof indiſputable, that the action of the body A is equal to that of B, and that their forces are properly meaſured by their moments, which are equal, becauſe their velocities are in the ſimple inverſe ratio of the bodies. Their opponents think it equally proved, by the unequal depths to which the pegs have penetrated, that the cauſes of theſe effects are unequal, as they find to be the caſe in their eſtimation of the forces by the ſquares of the velocities.

One party is ſatisfied, that equal *momenta* can reſiſt equal preſſures during the ſame *time*; the other party attend to the ſpaces through which the ſame moving force is exerted, and finding them in the proportion of two to one, are convinced that the *vis viva* of a body in motion is juſtly eſtimated by its magnitude, and the ſquare of its velocity jointly.

The former conception of a quantity dependent on the continuance of a given *vis motrix* for a certain *time*, may have its uſe, when correctly applied, in certain philoſophical conſiderations; but the latter idea of a quantity reſulting from the ſame force, exerted through a determinate *ſpace*, is of greater practical utility, as it occurs daily in the uſual occupations of men; ſince any quantity of work performed is always appreciated by the extent of effect reſulting from their exertion; for it is well known, that the raiſing any great weight forty feet would require four times as much labour, as would be requiſite to raiſe an equal weight to the height of ten feet; and that in its ſlow deſcent, the former would produce four times the effect of the latter, in continuing the motion of any kind of machine. Moreover, if the weights ſo raiſed were ſuffered to fall freely through the heights that have been aſcended, by means of four and of one minutes' labour, the velocities acquired would be in the ratio of two to one; and the ſquares of the velocities in proportion to the quantities of labour from which they originated, as four to one; and if the forces acquired by their deſcent were employed in driving piles, their more ſudden effects produced would be found to be in that ſame ratio.

This

This ſpecies of force has been, firſt by Bernouilli, and afterwards by Smeaton, very aptly denominated mechanic force; and when by force of percuſſion is meant the quantity of mechanic force poſſeſſed by a body in motion to be eſtimated by its quantity of mechanic effect, I apprehend that it cannot be controverted, that it is in proportion to the magnitude of the body, and to the ſquare of its velocity jointly.

But of this quantity of force Newton no where treats, and has accordingly given no definition of it. If, after defining what he meant by the *quantitas acceleratrix*, and *quantitas motrix*, he had had occaſion to convey an equally diſtinct idea of the *quantitas mechanica*, reſulting from the continued action of any force, he might not improbably have proceeded conformably to the definition given by Smeaton, and have added, "quantitas mechanica eſt menſura proportionalis ſpatio per quod data vis motrix exercetur;" or, if ſpeaking with reference to the accumulated energy communicated to a body in motion, "proportionalis quadrato velocitatis quam in dato corpore generat."

But if we attend to the firſt words of his preface to the firſt edition of his "Principia," he evidently had no need of ſuch a definition; "Nos autem non artibus ſed philoſophicæ conſulentes, deque potentiis non in manualibus ſed naturalibus ſcribentes," &c. and again nearly to the ſame effect in the ſcholium which follows the laws of motion; "Cæterum mechanicam tractare non eſt hujus inſtituti."

Dr. Wollaſton proceeds to obſerve, that if it be of any real utility to give the name of force to this complicated idea of *vis motrix* extended through time, as well as that of momentum to its effects when unreſiſted, it would be requiſite to diſtinguiſh this force always by ſome ſuch appellation as *momental* force; for it is to be apprehended, that for want of this diſtinction, many writers themſelves, and it is certain, that many readers of diſquiſitions on this ſubject, have confounded and compared together *vis motrix*, *momentum*, and *vis mechanica*; quantities, that are all of them totally diſſimilar, and bear no more compariſon to each other than lines to ſurfaces, or ſurfaces to ſolids.

In practical mechanics, however, it is, at leaſt very rarely, that the momentum of bodies is in any degree an object of conſideration; the ſtrength of machinery being in every caſe to be adapted to the *quantitas motrix*, and the extent and value of the effect to be produced depending on the *quantitas mechanica* of the force applied, or in other words to the ſpace through which a given *vis motrix* is exerted.

The comparative velocities given by different quantities of mechanic force to bodies of equal or unequal magnitude, have been ſo diſtinctly treated of by Smeaton, (Phil. Tranſ. vol. 66. p. 450.) in a ſeries of moſt direct experiments, that it would be a needleſs waſte of time to re-conſider them in this place. So alſo, on the contrary, the quantities of extended mechanic effect, producible by bodies moving with different quantities of impetus, have been as clearly traced by the ſame accurate experimentaliſt; (vol. 72. p. 337.)

But there is one view in which the comparative forces of impact of different bodies were not examined by Smeaton, and it may be worth while to ſhew that when the whole energy of a body A is employed without loſs in giving velocity to a ſecond body B, the impetus which B receives is, in all caſes, equal to that of A, and the force transferred to B, or by it to any third body C, (if alſo communicated without loſs, and duly eſtimated as a mechanic force,) is always equal to that from which it originated.

As the ſimpleſt caſe of entire transfer, the body A may be ſuppoſed to act upon B in a direct line, through the medium of a light ſpring, ſo contrived, that the ſpring is prevented by a ratchet from returning in the direction towards A, but expands again entirely in the direction towards B, and by that means exerts the whole force which had been wound up by the action of A in giving motion to B alone. In this caſe, ſince the moving force of the ſpring is the ſame upon each of the bodies, the accelerating force acting upon B at each point, is to the retarding force oppoſed to A at the correſponding points, in the reciprocal ratio of the bodies; and the ſquares of the velocities produced and deſtroyed by its action through a given ſpace will conſequently be in that ſame ratio. The momentum, which is in the ſimple reciprocal ratio of the bodies, might conſequently be increaſed at pleaſure by the means propoſed, in the ſubduplicate ratio of the bodies employed; and if momentum were an efficient force, capable of reproducing itſelf, and of overcoming friction in proportion to its eſtimated magnitude, the additional force acquired by ſuch a means of increaſe might be employed in counteracting the uſual reſiſtances, and perpetual motion would be effected. But ſince the impetus remains unaltered, it is evident that the utmoſt which the body B could effect in return, would be the reproduction of A's velocity, and reſtitution of its entire mechanic force, neither increaſed nor diminiſhed, excepting by the neceſſary imperfection of machinery. The poſſibility of perpetual motion is, conſequently, inconſiſtent with thoſe principles which meaſure the quantity of force by the quantity of its extended effect, or by the ſquare of the velocity which it can produce.

In eſtimating the utmoſt effect which one body can produce upon another at reſt, the ſame reſult is obtained by employing impetus as aſcenſional force, according to Huygens; for if the body A were allowed to aſcend to the height due to its velocity, and if, by any ſimple mechanical contrivance of a lever or otherwiſe, the body B were to be raiſed by the aſcent of A, it is well known that the heights of aſcent would be reciprocally as the bodies; and conſequently, that the *ſquare* of the velocity to be acquired by free deſcent of B would be in that ratio, and the quantity of mechanic force would be preſerved, as before, unaltered.

It may be of uſe alſo to conſider another application of the ſame energy, and to ſhew more generally that the ſame quantity of total effect would be the conſequence, not only of direct action of bodies upon each other, but alſo of their indirect action through the medium of any mechanical advantage or diſadvantage, although the time of action might by that means be increaſed or decreaſed in any deſired proportion. For inſtance, if the body ſuppoſed to be in motion were to act, by means of a lever, upon a ſpring placed at a certain diſtance from the centre of motion, the retarding force oppoſed to it would be inverſely as the diſtance of the body from the centre; and ſince the ſpace through which the body would move to loſe its whole velocity would be reciprocally as the retarding force, the angular motion of the lever and ſpace through which the ſpring muſt bend would be the ſame at whatever point of the lever the body acted. And converſely, the re-action of the ſpring upon any other body B would, in all poſitions, communicate to it the ſame velocity.

It may be remarked, however, that the times in which theſe total effects are produced may be varied at pleaſure, in proportion to the diſtances at which the bodies are placed from the centre of motion; and it ſhould not paſs unobſerved, that although the intenſity of any *vis motrix* is increaſed by being placed at what is called a mechanical advantage; yet, on the contrary, any quantity of mechanic force is not liable

to increaſe or diminution by any ſuch variation in the mode of its application.

Since we can, by means of any mechanic force, conſiſting of a *vis motrix* exerted through a given *ſpace*, give motion to a body for the purpoſe of employing its *impetus* for the production of any ſudden effect, or can, on the contrary, occaſion a moving body to aſcend, and thus reſolve its impetus into a moving force, ready to exert itſelf through a determinate ſpace of deſcent, and capable of producing preciſely the ſame quantity of mechanic effect as before, the force depending on impetus may juſtly be ſaid to be of the ſame kind as any other mechanic force, and they may be ſtrictly compared as to quantity. In this manner we may even compare the force of bodies in motion to the ſame kind of force contained in a given quantity of gun-powder, and may ſay, that we have the ſame quantity of mechanic force at command, whether we have one pound of powder, which by its expanſion could give one ton weight a velocity ſufficient to raiſe it through forty feet, or the weight actually raiſed to that height, and ready to be let down gradually, or the ſame weight, poſſeſſing its original velocity, to be employed in any ſudden exertion.

By making uſe of the ſame meaſure as in the former caſes, a diſtinct expreſſion is likewiſe obtained for the quantity of mechanic force given to a ſteam-engine by any quantity of coals; and we are enabled to make a compariſon of its effect, with the quantity of work that one or more horſes may have performed in a day, each being expreſſed by the ſpace through which a given moving force is exerted. In the caſe of animal exertion, however, conſiderable uncertainty always prevails, in conſequence of the unequal powers of animals of the ſame ſpecies, and varying vigour of the ſame animal. The information which the author of this paper has received, in reply to inquiries reſpecting the weights raiſed in one hour by horſes in different ſituations, has varied as far as from ſix to fifteen tons to the height of one hundred feet. But although the height at which mechanic force is generated may vary, any quantity of work exeeuted is the ſame, in whatever time it may have been performed.

In ſhort, whether we are conſidering the ſources of extended exertion or of accumulated energy, whether we compare the accumulated forces themſelves by their gradual, or by their ſudden efforts, the idea of mechanic force in practice is always the ſame, and is proportional to the *ſpace* through which the moving force is exerted or overcome, or to the *ſquare* of the velocity of a body in which ſuch force is accumulated.

Comparative table of mechanical forces, extracted from Dr. Young's lectures.—In order to compare the different eſtimates of the force of moving powers, it will be convenient to take a unit, which may be conſidered as the mean effect of the labour of an active man, working to the greateſt poſſible advantage, and without impediment. This will be found, on a moderate eſtimation, ſufficient to raiſe 10 pounds 10 feet in a ſecond, for 10 hours in a day; or to raiſe an 100 pounds, which is the weight of 12 wine gallons of water, 1 foot in a ſecond, or 36,000 feet in a day; or 3,600,000 pounds, or 432,000 gallons, 1 foot in a day. This we may call a force of 1 continued 36,000″.

Immediate force of men, without deduction for friction.

	Force.	Continuation.	Day's Work.
A man, weighing 133 pounds Fr. aſcended 62 feet Fr. by ſteps in 34″, but was completely exhauſted. Amontons.	2.8	34″	
A ſawyer made 200 ſtrokes of 18 inches Fr. each, in 145″, with a force of 25 pounds Fr. He could not have gone on above 3 minutes. Amontons.	6.	145″	
A man can raiſe 60 pounds Fr. 1 foot Fr. in 1″ for 8 hours a day. Bernouilli.	69.	8h	.552
A man of ordinary ſtrength can turn a winch with a force of 30 pounds, and with a velocity of $3\frac{1}{2}$ feet in 1″, for 10 hours a day. Deſaguliers.	1.05	10h	1.05
Two men, working at a windlaſs with handles at right angles, can raiſe 70 pounds more eaſily than one can raiſe 30. Deſaguliers.	1.22		1.22
A man can exert a force of 40 pounds for a whole day, with the aſſiſtance of a fly, when the motion is pretty quick, as about 4 or 5 feet in 1″. Deſaguliers, lect. 4th. But from the annotation it appears to be doubtful whether the force is 40 pounds or 20.	2.		.2
For a ſhort time a man may exert a force of 80 pounds with a fly, "when the motion is pretty quick." Deſaguliers.	3.	1″	
A man going up ſtairs aſcends 14 metres in 1′. Coulomb.	1.182	1′	
A man going up ſtairs for a day raiſes 205 chiliogrammes to the height of a chiliometre. Coulomb.			.412
With a ſpade a man does $\frac{12}{20}$ as much as in aſcending ſtairs. Coulomb.			.391
With a winch a man does $\frac{5}{8}$ as much as in aſcending ſtairs. Coulomb.			.258
A man carrying wood up ſtairs raiſes, together with his own weight, 109 chiliogrammes to 1 chiliometre. Coulomb.			.219
A man weighing 150 pounds Fr. can aſcend by ſtairs 3 feet Fr. in 1″ for 15″ or 20″. Coulomb.	5.22″	20″	
For half an hour, 100 pounds Fr. may be raiſed 1 foot Fr. in 1″. Coulomb.	1.152	30′	
According to Mr. Buchanan's compariſon, the force exerted in turning a winch being made equal to the unit, the force in pumping will be	.61		
In ringing	1.36		
In rowing	1.43		
Allowing the accuracy of Euler's formula confirmed by Schulze,			

ſuppoſing

	Force.	Continuation.	Day's Work.
ſuppoſing a man's action to to be a maximum when he walks $2\frac{1}{2}$ miles an hour, we have $7\frac{1}{2}$ for his greateſt velocity, $.04\ (7\frac{1}{2} - v)^2$ for the force exerted with any other velocity, and $.0160\ (7\frac{1}{2} - v)^2$ for the action in each caſe; thus, when the velocity is one mile an hour, the action is	.676		
When two miles	.964		
Three	.972		
Four	.784		
And when five	.5		

And the force in a ſtate of reſt becomes $2\frac{1}{4}$, or about 70 pounds; with a velocity of two miles, 36 pounds; with three, 24 pounds; and with four, 15.

It is obvious that in the extreme caſes this formula is inaccurate, but for moderate velocities it is probably a tolerable approximation.

Coulomb makes the maximum of effect when a man, weighing 70 chiliogrammes, carries a weight of 53 up ſtairs, but this appears to be too great a load; he conſiders 145 chiliogrammes as the greateſt weight that can be raiſed. He obſerves that in Martinique, where the thermometer is ſeldom below 68°, the labour of Europeans is reduced to one half.

Harriot aſſerts that his pump, with a horizontal motion, enables a man to do one-third more work than the common pump with a vertical motion.

Porters carry from 200 to 300 pounds at the rate of three miles an hour; chairmen walk four miles an hour with a load of 150 pounds each; and it is ſaid that in Turkey there are porters who, by ſtooping forward, carry from 700 to 900 pounds placed very low on their backs.

The moſt advantageous weight for a man of common ſtrength to carry horizontally is 111 pounds; or if he returns unladen, 135. With wheel barrows, men will do half as much more work as with hods. Coulomb.

Performance of men by machines.

	Force.	Continuance.	Day's Work.
A Man raiſed by a rope and pulley 25 pounds Fr. 220 feet Fr. in 145″. Amontons.	.436	.145″	
A man can raiſe, by a good common pump, a hogſhead of water 10 feet high in a minute, for a whole day. Deſaguliers.	.875		.875
By the mercurial pump, or another good pump, a man may raiſe a hogſhead 18 or 20 feet in a minute, for one or two minutes.	1.61	1′	
In a pile engine, $55\frac{1}{3}$ pounds Fr. were raiſed one foot Fr. in 1″, for five hours a day, by a rope drawn horizontally. Coulomb.	.64	5h	.82
Robiſon ſays, that a feeble old man raiſed ſeven cubic feet of water $11\frac{1}{2}$ feet in 1′, for eight or 10 hours a day, by walking backwards and forwards on a lever. Enc. Br.	.837	9h	.753
A young man weighing 135 pounds, and carrying 30, raiſed $9\frac{1}{4}$ cubic feet $11\frac{1}{2}$ feet high, for 10 hours a day, without fatigue. Robiſon.	1.106	10h	1.106
Wynne's machine enables a man to raiſe a hogſhead 20 feet in a minute. Y.	1.75	1′	

Force of Horſes.

Two horſes, attached to a plough on moderate ground, exerted each a force of 150 Fr. Amontons. We may ſuppoſe that they went a little more than two miles an hour, for eight hours.	5.4	8h	4.32
A horſe draws with the greateſt advantage when the line of direction is level with his breaſt; and he can draw with a force of 200 pounds, $2\frac{1}{2}$ miles an hour, for eight hours in the day.	7.33	8h	5.87
With a force of 240 only ſix hours. On a carriage, indeed, where friction alone is to be overcome, a middling horſe will draw 1000lb. Deſaguliers.	8.8	6h	5.28
The mean draught of four horſes was 36 myriogrammes each, or 794 pounds. Regnier. This muſt have been momentary. Suppoſing the velocity two feet in a ſecond, the action would have been	15.88	1″	
By means of pumps a horſe can raiſe 250 hogſheads of water, 10 feet high, in an hour. Smeaton's Reports.	3.64	1h	

A horſe can in general draw no more up a ſteep hill than three men can carry, that is, from 450 to 750 pounds, but a ſtrong horſe can draw 2000 pounds up a ſteep hill, which is but ſhort. The worſt way of applying the force of a horſe, is to make him carry or draw up hill: for, if the hill be ſteep, three men will do more than a horſe, each man climbing up faſter with a burden of 100lb. weight, than a horſe that is loaded with 300lb. a difference which is owing to the poſition of the parts of the human body being better adapted to climb than thoſe of a horſe.

On the other hand, the beſt way of applying the force of a horſe, is an horizontal direction, wherein a man can exert leaſt force: thus a man, weighing 140lb. and drawing a boat along, by means of a rope coming over his ſhoulders, cannot draw above 27lb. or exert above one ſeventh part of the force of a horſe employed to the ſame purpoſe.

The very beſt and moſt effectual poſture in a man is that of rowing; wherein he not only acts with more muſcles at once for overcoming the reſiſtance than in any other poſition; but as he pulls backwards, the weight of his body aſſiſts by way of lever. Deſaguliers.

The diameter of a walk for a horſe-mill ought to be at leaſt 25 or 30 feet. Deſaguliers.

Some horſes have carried 650 or 700 pounds, ſeven or

eight miles without reſting, as their ordinary work; and a horſe at Stourbridge carried 11 hundred weight of iron, or 1232 pounds for eight miles. Deſaguliers, Exp. Philoſ. vol. i.

	Force.	Continuance.	Day's Work.
Work of Mules.			
Cazanel ſays, that a mule works in the Weſt Indies two hours, out of about 18, with a force of about 150 pounds, walking three feet in a ſecond.	4.5	$2^h\ 40'$	1.2

Inanimate force.—According to M. Coulomb, a windmill with four ſails, meaſuring 66 feet Fr. from one extremity to that of the oppoſite ſail, and ſix feet wide, or a little more, is capable of raiſing 1000 pounds Fr. 218 feet in 1′, and of working on an average eight hours in a day. This is equivalent to the work of 34 men, as it has been above eſtimated, 25 ſquare feet of canvas performing about the daily work of a man.

Robiſon ſays, that a hundred weight of coals burned in a ſteam engine will raiſe at leaſt 20,000 cubic feet of water 24 feet high; this is equivalent to the daily labour of 8.32 men. A ſteam engine in London, with a 24-inch cylinder, does the work of 72 horſes, and a chaldron of coals in a day; each buſhel being equivalent to two horſes, and each ſquare inch of the cylinder performing nearly the work of a man.

If we calculate the quantity of motion produced by gunpowder, we ſhall find that this agent, though extremely convenient, is far more expenſive than human labour; but the advantage of gun-powder conſiſts in the great rarity of the acting ſubſtance. A ſpring or a bow can only act with a moderate velocity on account of its own weight. The air of the atmoſphere, however compreſſed, could not flow into a vacuum, with a velocity ſo great as 1500 feet in a ſecond. Hydrogen gas might move more rapidly, but the elaſtic ſubſtance produced by gun-powder is capable of propelling a very heavy cannon ball with a much greater velocity.

It is ſaid that nine tons of water, falling 10 feet, will grind and dreſs a buſhel of wheat; conſequently a man might do the ſame in $33'\ 36''$.

FORCE, *Accelerating.* See VIS *acceleratrix*, and ACCELERATION.

FORCE, *Attractive.* See ATTRACTION.

FORCE, *Central.* See CENTRAL.

FORCE, *Centrifugal.* See CENTRIFUGAL.

FORCE, *Centripetal.* See CENTRIPETAL.

FORCE *of Cohesion.* See COHESION.

FORCE, *Contractile.* See CONTRACTILE.

FORCE, *Elaſtic.* See ELASTIC, and ELASTICITY.

FORCE, *Electrical.* See ELECTRICITY.

FORCE *of Gravity.* See GRAVITY.

FORCE *of the Heart.* See HEART.

FORCE *of Inactivity.* See VIS *inertiæ*.

FORCE, *Innate.* See VIS *inſita*.

FORCE, *Magnetic.* See MAGNETISM.

FORCE, *Moving.* See VIS *motrix*, and preceding article, FORCE.

FORCE, *Repelling.* See REPULSION.

FORCE, *Reſiſting.* See RESISTANCE.

FORCE, *Retarding.* See RETARDATION.

FORCE *of Wind.* See WIND, &c.

FORCE, in *Common Law*, ſignifies an offence, by which violence is uſed either to perſons, or things.

Force is either *ſimple*, or *compound.*

FORCE, *Mixed* or *compound*, is violence committed with ſome fact, which of itſelf alone were criminal: as if any man by force enter into another man's poſſeſſion, and there kill a man or raviſh a woman, &c. See HOMICIDE.

FORCE, *Simple*, is that which has no other crime adjoined to it: if one, by force, enter into another man's poſſeſſion, without doing any other unlawful act.

FORCE is alſo divided into *true force*, or *force after a ſort.*

There are other branches; as forcible entries, forcible detaining, or holding unlawful aſſembly, routs, riots, rebellions, &c. See the ſeveral articles.

FORCE, *Freſh.* See FRESH.

FORCE, in *Grammar*, and ſome other arts, is applied to a thing which ſtands in lieu of, or has the ſame effect, as another. In our language the *ſ* between two vowels has the force or power of a *z*, and is ſometimes put for a *z*: as in horiſon, baptiſing, &c.

In Hebrew, the dageſh; and in Arabic, the teſdid, have the force of a letter ſuppreſſed. An unit before a cypher has the force of ten.

FORCE, Fr. and Eng. in *Muſic*, implies energy, ſtrength, loudneſs, intenſity. Force not only renders ſound more diſtinct, but audible at a greater diſtance; as the greater or leſs number of vibrations of a ſonorous body renders it more acute or grave, its greater or leſs deviation from the line of repoſe conſtitutes *loud* or *ſoft.* But if this deviation is too great, and an inſtrument or voice is forced, the ſound becomes noiſe, and ceaſes to be appreciable. To force the voice beyond its power, in order to be better heard in a large room or theatre, deſtroys all its proportions, by exceeding its diapaſon, or ſcale of ſounds, and becomes ſcreaming inſtead of ſinging. Forcing the tone has the ſame effect on inſtruments, whether their ſounds are produced by a bow, or by wind: and it is for this reaſon that the French ſo ſeldom ſing in tune. Rouſſeau.

FORCE, in *Painting*, is uſed to ſignify the degree of relievo of the objects in a picture, effected by the contraſt of colours employed either in oppoſition of hue, or of light and dark. In other words, it marks the degree of their approach in effect, to the natural appearance of the original in nature. Force, therefore, in this view, correſponds in meaſure with effect in painting (ſee EFFECT); but its uniſon with it is confined to this point alone.

Though it is a quality of a very uſeful kind when judiciouſly applied in a picture, it is by no means neceſſary to apply it always powerfully; as it will not only in ſome caſes be unavailing in giving value to the work, but may be of actual injury to its effect on the mind, in beauty and character of expreſſion; *e.g.* in ſubjects of a tender and delicate nature. In them the poſitive relievo of objects, which great force implies, would rather produce diſguſt, than afford delight; and inſtead of giving the ſoft and pleaſing expreſſion of their nature, would, by impoſing itſelf too powerfully on the ſight, deſtroy the effect moſt deſirable to be produced.

Even in portraits, particularly of ladies where the expreſſion is of a mild and amiable character, too eager a deſire to produce the appearance of *reality* or *force*, by deſtroying the beauty, renders the work unpleaſant. The object is more agreeably viewed, when ſeen through a ſlight degree of miſt, or when the tones of ſhade are weakened by a ſlight medium of air paſſing between the object and the obſerver.

In thoſe of men in general, particularly if their characters are ſtrongly marked, of a bold or grand kind, and expreſ-

ſion of truth, more than beauty, is aimed at, too much force cannot be given to them. A full and rich relievo heightens their importance, and gives a dignity to the other qualities of the work, which, without that, would be tame and inſipid, when compared with the originals in nature.

Its utility is very great in ſubjects of horror, wherein ſtrong contraſts of light and ſhade aid the effect of the ſubject, and ſtrengthen its impreſſion on the mind. In thoſe of ordinary intereſt, and in all repreſentations of ſtill life, it cannot fail of being beneficial; where the nearer the objects approach in brilliancy of effect to nature, the more perfect is the work.

It is beſt produced by uſing a ſtrong contraſt of light and dark; but mere contraſt alone will not produce it perfectly; a delicate gradation of ſhade and hue muſt be given, and great attention paid to the rounding of the parts to give relievo; for it is upon the relievo that force depends.

The moſt powerful, and the ſimpleſt mode of obtaining force, is by laying a light figure on a dark ground; particularly if the figure is compoſed of ſtrong and vivid colours, ſuch as red, or yellow, aided by white; and with ſome of the ſhadows darker than the ground. This contraſt, properly perfected in the execution, will produce deception; giving the appearance of a complete detachment of the figure from the ground: eſpecially if ſeen under favourable circumſtances, and the boundary of the picture is hid.

But it is not on this kind of contraſt alone that force depends; it has been often produced by ſkilful maſters, with thoſe of a leſs violent nature, at leaſt not ſo conſpicuouſly employed for the purpoſe. A picture muſt, however, in order to poſſeſs it, have great oppoſition in its parts; although it is not neceſſary that thoſe parts of different qualities come into immediate contact.

The moſt effective examples of this quality in painting among the old artiſts, are the works of Michael Angelo, Carravaggio, and Spagnoletto. But they have been both ſurpaſſed by our late royal academician Opie; whoſe figures in many of his hiſtorical works appear actually relieved from the canvas, and embodied. But whatever degree each of theſe artiſts has added of ſingularity to painting, they have not increaſed its beauty, nor heightened its effect in ſublimity of expreſſion, by the degree of force they have given to their works.

The gratification of the mind in beholding the cartoons of Raphael, when the eye is accuſtomed to their imperfect colouring, is a clear proof, that painting is not indebted to force for its moſt powerful ſenſations on the human mind; though, when properly employed, it is a very valuable aſſiſtant to the other more valuable parts of the art.

FORCELLER, in *Geography*, a town of Naples, in Abruzzo Ultra; 3 miles E. of Teramo.

FORCEPS, in *Agriculture*, is a term which is applied to a ſort of tool of the nipper kind, that is frequently employed in weeding broad-caſt crops of corn, or other ſorts; and which may be uſed for various other purpoſes.

Forceps, in *Midwifery*, an inſtrument uſed to facilitate the birth of the child, when the head is too large to paſs readily through the pelvis of the mother, and to effect this object without doing injury to either party. The forceps conſiſts of two ſeparate pieces, or blades; each of them, including the handles, about twelve inches in length; curved at their upper ends, to accommodate them to the ſhape of the head of the child; and at the end of the curvature, where the handles commence, furniſhed with a contrivance, by which they may be united, or locked together, ſo as to act as one inſtrument in moving and bringing down the head of the child. In uſing the forceps, the accoucheur is to paſs two or three fingers, generally of the right hand, into the vagina, along the ſide of the head of the child, over the ear, if practicable; and then, with the other hand, direct one of the blades of the forceps, anointed with lard, between his fingers and the head, keeping the handle of the inſtrument back towards the anus of the woman. Having puſhed up the blade beyond the ear of the child, he then withdraws his fingers, keeping the inſtrument ſteady in the paſſage, and proceeds to paſs the other blade over the other ear of the child, directly oppoſite to the firſt. The handles of the forceps are now to be brought together, and locked; taking care that neither the hair nor any of the ſoft parts of the woman are included. The handles muſt alſo be tied together, that in the courſe of extracting the child, which muſt be done ſlowly and gradually, they may not ſlip from the head, and ſubject you to the trouble of replacing them.

Some ſpecies of forceps appear to have been very early introduced into the practice of midwifery, as we find them mentioned by Hippocrates, and afterwards by Avicenna. They were probably intended to ſuperſede the uſe of hooks, and various cutting inſtruments, with which it had been uſual to open and reduce the ſize of the head of the child, when it was too large to paſs through the brim of the pelvis. They were the ſame as thoſe uſed by ſurgeons in removing ſplinters of bones; were generally armed with teeth, and the blades were united by a fixed joint. The two blades were, therefore, neceſſarily introduced into the vagina together, and there opened to take hold of the head of the child. In this way, beſides the danger, almoſt inevitable, of lacerating the os uteri of the woman, the ſcalp of the child was liable to be bruiſed and torn; and, if the reſiſtance was conſiderable, the bones of its ſkull to be cruſhed, and its life to be deſtroyed.

Such muſt have been the caſe on uſing the forceps deſcribed and delineated by Albucaſis, who is ſuppoſed to have lived about the beginning of the twelfth century, 100 years after Avicenna; or thoſe deſcribed by Ruett, ſurgeon at Zurich, in his book "De Conceptione et Generatione Hominis," publiſhed in 1554. Great credit is therefore due to Dr. Chamberlen, (ſee his life,) who firſt conceived the idea of making a pair of forceps, ſuch as has been deſcribed above, conſiſting of two moveable blades, that were to be introduced ſeparately into the uterus, and to be united and locked together, after they had taken hold of the head of the child. This was about the year 1672.

Chamberlen carefully abſtained from giving any deſcription of his invention. He does not even intimate it was an inſtrument. In his tranſlation of "Momeicrans Practica des Accouchmens," publiſhed in 1683, he ſays, "My father, brothers, and myſelf, (though none elſe in Europe that I know,) have, by God's bleſſing, and our induſtry, attained to and long practiſed a way to deliver women, when the head of the child, on account of ſome difficulty, or diſproportion, cannot paſs, without any prejudice to them or their infants," &c. Chapman firſt publiſhed a delineation and deſcription of the forceps, with the method of uſing them, in his Treatiſe on the Improvement of Midwifery, publiſhed in 1732. (See the article *Edmund Chapman*.) He made ſome improvements, he ſays, in their form. They have ſince been in general uſe, and have received various alterations, according to the fancy of different practitioners, particularly by M. Levret, by Dr. Johnſon, and Dr. Oſborne. But the moſt material and valuable improvements were made by Dr. Smellie, who gave them the hinge, or lock now generally uſed; and who ſimplified their ſtructure, and reduced them conſiderably in ſize,

ſize, which has added much to the facility and ſafety in uſing them. See his treatiſe on the Theory and Practice of Midwifery. For a more minute and particular account of the caſes in which the forceps are indicated, and of the method of applying them in every poſſible poſition of the head of the child, the reader is referred to Dr. Denman's excellent Introduction to the Practice of Midwifery, and to his Aphoriſms on the Application and Uſe of the Forceps and Vectis, which are, it is to be preſumed, in the hands of every practitioner in the art. For a delineation of the forceps, ſee *Plate of Midwifery*.

FORCEPS, in *Surgery*, is an inſtrument much employed for ſeveral purpoſes, and having accordingly various conſtructions. However, the general deſign of every ſurgical forceps is to take hold of ſubſtances, which cannot be conveniently got at with the fingers; and, of courſe, the inſtrument is always formed on the principle of a pair of pincers, having two blades, either with or without handles, according to circumſtances.

The ſmalleſt forceps is that which is employed in the operation of extracting the cataract, and which is uſeful for removing any particles of opake matter from the pupil, after the chief part of the cryſtalline lens has been taken away.

Another forceps of larger ſize is that uſed for taking up the mouths of the arteries, when it is neceſſary to tie theſe veſſels, in order to ſtop hemorrhage. This inſtrument is alſo frequently employed for taking dreſſings off ſores, removing pieces of dead bone, foreign bodies from wounds, &c. It reſembles the forceps contained in every caſe of diſſecting inſtruments, and is repreſented in the ſurgical plates. See *Plate* II.

Neither of the foregoing forceps is made with handles; each opens by its own elaſticity; and the ends of the blades only come into contact when preſſed together by the ſurgeon's fingers.

The following kinds of forceps are conſtructed with handles, by means of which they are both opened and ſhut:

1. The common forceps, contained in every pocket caſe of ſurgical inſtruments, and uſed for removing dreſſings from ſores, extracting dead portions of bone, extraneous ſubſtances, &c.

2. Larger forceps employed for extracting polypi from the noſe. See POLYPUS.

3. Forceps of different ſizes and conſtructions, uſed in the operation of lithotomy, for taking the ſtone out of the bladder, after an opening has been made into this organ. Alſo, another very ſtrong forceps with teeth, for breaking ſuch calculi as are too large to admit of being extracted whole. See plates.

FORCER, in *Mechanics*, is properly a piſton, without a valve.

There are ſeveral ways of making forcers: the moſt common of all conſiſts of a braſs cylinder, a very little leſs in diameter, at its bottom and top, than the bore of the barrel of the pump, and turned ſtill leſs at the middle, in order to let in a leathern ring or collar (made of a thick leather put round the braſs cylinder), which makes it juſt equal to the bore of the barrel, ſo as to fit it quite when it is put into it.

The ſecond ſort of forcers conſiſts of three braſs cylinders, which can be ſcrewed together. The middle one ought to be almoſt equal in diameter to the bore of the pipe, ſo as to ſlide in it without any friction. The upper cylinder and the lower muſt be a little leſs, and equal to one another. There are two leathers which muſt be put between them when they are unſcrewed: then it is evident, that if the cylinders be ſcrewed together, and the leathers, which ought to be a little bigger than the braſs cylinders, apply themſelves folding upwards round the upper cylinder, and downwards round the lower, they will become juſt equal to the bore of the barrel; and conſequently they will hinder any air from getting through the ſides of the forcer, when it moves up and down in the barrel. The uſe of the middle braſs cylinder is to hinder the leathers from turning themſelves back by the motion.

This kind of forcer has, above the other, the advantage of having a great deal leſs friction; and beſides, as the leathers, which are applied to it, may be thin ones, they are much ſmoother than thick ones, which are uſed in the other.

But the beſt way of making forcers is to have a plunger, or ſolid braſs cylinder, equal in length to the barrel of the pump, and a little leſs in the diameter than the bore, ſo that it may move freely in it without any friction. There muſt be two hollow, ſhort, braſs cylinders, or rather rings, at the top of the barrel, which can be ſcrewed together; the upper one muſt be equal in bore to the barrel, and the lower a little leſs; there are two leathers, both having in the middle a leſs hole than in the bore of the pipe; the one muſt be applied between the barrel and the lower ring, and the other between the ſame ring and the upper one; and the whole muſt be ſcrewed together. Then if the ſolid cylinder or forcer be put into it, and moved up and down, it is evident that the two before-mentioned leathers, which are applied the one to the barrel and the other to the inſide of the hollow cylinder, will hinder any air from getting between them and the ſolid cylinder.

The advantage of this kind of forcer is, that it has no other friction but at the top of the barrel, and that the inſide of the barrel need not be ſmooth, as in other kinds of pumps; but only the outſide of the forcer muſt be turned true and poliſhed, which can be done with much more eaſe, and the lower part muſt be turned a little conical, that it may be brought into the barrel, without any reſiſtance of the upper leather of the collar or jack-head. See Deſaguliers, Courſe of Experim. Philoſ. vol. ii. p. 161, 162.

FORCHEIM, in *Geography*, a town of Germany, in the biſhopric of Bamberg, on the Wiſent; 12 miles S. of Bamberg. N. lat. 49° 43′. E. long. 11°.—Alſo, a town of Germany, in the circle of Erzgeburg; 4 miles N. N. E. of Lauterſtein.

FORCHEN-SEE, a lake of Bavaria; 10 miles S. of Traunſtein.

FORCHTENBERG, a town of Germany, in the principality of Hohenlohe, ſituated on the Kocher; 6 miles N. N. E. of Ohringen.

FORCHTENSTEIN, a town of the duchy of Stiria; 3 miles S. of Windiſch-Gratz.

FORCIBLE ENTRY, a violent, actual entry into houſes, or lands, &c. with menaces or weapons, whether violence or hurt be offered to any perſon therein, or not. And forcible *holding*, or *detaining*, a withholding by violence, and with a ſtrong hand, of the poſſeſſion of land, &c. whereby he who has a lawful right of entry is barred or hindered. See ENTRY.

This was formerly allowable to every perſon diſſeiſed, or turned out of poſſeſſion, unleſs his entry was taken away, or barred by his own neglect, or other circumſtances. But this being found very prejudicial to the public peace, it was thought neceſſary, by ſeveral ſtatutes, to reſtrain all perſons from the uſe of ſuch violent methods, even of doing themſelves juſtice: ſo that the entry now allowed by

by law is a peaceable one. By the ſtatute 5 Ric. II. ſt. 1. c. 8. all forcible entries are puniſhed with impriſonment and ranſom at the king's will. And by the ſeveral ſtatutes of 15 Ric. II. cap. 2. 8 Hen. VI. cap. 9. 31 Eliz. cap. 11. and 21 Jac. I. cap. 15. upon any forcible entry, or forcible detainer after peaceable entry, into any lands, or benefices of the church, one or more juſtices of the peace, taking ſufficient power of the county, may go to the place, and there record the force upon his own view, as in caſe of riots; and upon ſuch conviction, may commit the offender to gaol, till he makes fine and ranſom to the king. And the juſtice or juſtices have power to ſummon a jury, to try the forcible entry or detainer complained of; and if the ſame be found by that jury, then, beſides the fine on the offender, the juſtices ſhall make reſtitution by the ſheriff of the poſſeſſion, without inquiring into the merits of the title; for the force is the only thing to be tried, puniſhed, and remedied by them; and the ſame may be done by indictment, at the general ſeſſions. But this proviſion does not extend to ſuch as endeavour to maintain poſſeſſion by force, where they or their anceſtors have been in the peaceable enjoyment of the lands and tenements for three years immediately preceding. Holding over by force, where the tenant's title was under a leaſe, now expired, is ſaid to be a forcible detainer. (Cro. Jac. 199.)

FORCIBLE *abduction* and *marriage*, vulgarly called "ſtealing an heireſs." By ſtat. 3 Hen. VII. cap. 2. it is enacted, that if any perſon ſhall, for lucre, take any woman, being maid, widow, or wife, and having ſubſtance, either in goods or lands, or being heir apparent to her anceſtors, contrary to her will; and afterwards ſhe be married to ſuch miſdoer, or by his conſent to another, or defiled; ſuch perſon, and all his acceſſaries, ſhall be deemed principal felons: and by ſtat. 39 Eliz. cap. 9. the benefit of clergy is taken away from all ſuch felons, who ſhall be principals, procurers, or acceſſaries before the fact. See MARRIAGE.

FORCING, in the *Wine-trade*, a term uſed by the wine-coopers for the fining down wines, and rendering them fit for immediate draught. See FINING.

The principal inconvenience of the common way of fining down the white wines by iſinglaſs, and the red by whites of eggs, is the ſlowneſs of the operation; theſe ingredients not performing their office in leſs than a week, or ſometimes a fortnight, according as the weather proves favourable, cloudy or clear, windy or calm: this appears to be matter of conſtant obſervation. But the wine-merchant frequently requires a method that ſhall, with certainty, make the wines fit for taſting in a few hours. A method of this kind there is, but it is kept in a few hands a valuable ſecret. Perhaps it depends upon a prudent uſe of a tartarized ſpirit of wine, and the common forcing, as occaſion is, along with gypſum, as the principal; all which are to be well ſtirred about in wine, for half an hour before it is ſuffered to reſt. Shaw's Lectures, p. 208.

FORCING, in *Gardening*, is the art of raiſing and producing plants, flowers, and fruits, at an earlier ſeaſon than the natural one, by means of artificial heat. It is accompliſhed, either by the gentle moiſt heat that is evolved during the fermentation and decompoſition of ſtable-dung, tanner's bark, leaves, and other ſimilar materials, or by the uſe of actual fire in ſtoves, flues, pits, and other contrivances formed for the purpoſe of producing ſuch effects.

It is the former of theſe methods that is principally employed in raiſing cucumbers, melons, and ſome other fruits; and the latter which is made uſe of in producing pine-apples, various kinds of wall-fruits, and ſeveral other ſorts of vegetable productions of the early fruit, or other kinds.

It may be obſerved, that the great difficulty in the management of this proceſs is that of adapting and regulating the heat, of whatever ſort it may be, in ſuch a manner as to promote and bring forward the plants, flowers, or fruits in the moſt perfect and healthy growth and ſtate of production, without their ſuſtaining any check or injury either by a deficiency or exceſs.

The various methods of effecting this in the moſt perfect manner are fully deſcribed under the culture of the different trees, plants and vegetables that require ſuch treatment in their growth, and production of fruit.

It is by this proceſs that different ſorts of rare vegetable productions, fruits and flowers are afforded at much earlier periods than could otherwiſe be the caſe; it of courſe conſtitutes an important branch of practical gardening in the preſent improved ſtate of the art; and is applicable in a variety of intentions, as ſhewn and deſcribed in the way hinted above. See CUCUMIS, in *Gardening*.

FORCING-*frame*, that kind of large frame-work or other erection which is made uſe of in procuring different ſorts of vegetables, fruits, and flowers at an early period by the application of artificial heat in ſome of the modes uſually employed. It is a ſort of conſtruction that is covered with ſloping glaſs ſliding frames on the top, and ſometimes in the front. It may be either fixed or moveable, but in the former caſe the walls are moſtly made of brick work, or ſome other hard durable material.

Theſe ſorts of forcing frames are uſually contrived ſo as be placed full to the ſouth ſun; and their lengths may be various, from ten to fifty or even one hundred feet; the widths being from five to fifteen, and from five to ten in height; having an upright back-wall, of wood, where they are ſmall, but when large, of brick, with a front of glaſs-work, made ſometimes in one continued range of ſlope to the top of the back-wall; and ſometimes with upright glaſs-work, head high, ranging immediately along the front, and from the top of which a glaſs roof is carried to the top of the back or main wall: when the frames are wrought by dung-heat, it is chiefly applied againſt the outſide of the back-wall, and by being formed into a bed internally; but when by bark-heat, by forming it into a bed in a pit within-ſide the frame; and when by fire heat, by having ſeveral returns of flues formed againſt the inſide of the back-wall, and ſometimes againſt thoſe of the front and both ends, for the heat to paſs along, conſtructed with proper fire places, according to the ſorts of plants that are chiefly intended to be forced, and the nature of the materials to be employed in producing the heat that may be requiſite.

In caſes where the firſt kind of material is employed in affording heat, the frame is uſually formed with an upright back and ends of deal planking, and a ſloping front of moveable glaſs-lights; the length being ten, twenty, or thirty feet, or more in different pieces; the width, from three to five or more, and five or ſix in height; the frame work being of inch and half deal planking, tongued, and cloſely joined, that no ſteam from the dung may penetrate into the frame; and raiſed five, ſix, or ſeven feet in height behind, but only ten or twelve inches in front, both ends being made anſwerable to the front and back; the glaſs-work ranging from the upright in front, ſloping upward towards the back-wall, to about a foot width at the top, where the ends ſhould reſt upon a proper frame-work of wood; and bars or bearers, three inches in width, placed in a ſloping

a ſloping manner from the back to front, for the ſupport of the lights, as in common hot-bed frames; the top of all being boarded and made wind and water tight. The frames have ſometimes within-ſide them two or three ranges of narrow ſhelves fixed up along the back and ends, for pots of ſmall plants, and the bottom levelled, on which to place pots of larger kinds; theſe ſhelves may alſo be made in a riſing manner one behind another quite from the front half way up the back wall, in order to place the loweſt plants in front and the others in order behind them, riſing gradually to the talleſt in the back rows of the frames.

In managing the working of theſe frames, after having placed the pots of plants in regular order, the lights are put on, and a ſufficient quantity of freſh hot ſtable-dung, prepared as for common dung hot-beds, is to be piled up cloſe againſt the outſide of the back and ends, a yard in width at bottom, drawing it gradually into a foot in width at the top, and finiſhing it ſomewhat in a ſloping manner to throw off the wet: as the dung ſettles or ſinks down, a freſh ſupply muſt be added at the top, to maintain the linings to the full height of the frame; additions being occaſionally made of freſh dung as the heat declines, by which means a fine growing heat will be thrown into the frame. See HOT-*bed*.

In caſes where bark is made uſe of in producing the heat, the frame may be conſtructed either of wood or brick-work, and fronted, &c. with ſaſhes of glaſs, as in the former; the length being ten, twenty, or thirty feet, or more; eight or ten in width, and ſix or eight in height; and, like the dung-heat frame, be ſix or eight feet in height behind, and one in front, the ends being made conformable and ſloping, having glaſs work frames raiſed from the front in a ſloping manner, either quite to the top of the back-wall, or inclined only about one half towards that part, meeting a tiled roof at top half way, which ſhould be raiſed high enough in front to throw the water off behind, as well as to admit as much ſun as poſſible to every part of the frame: it may likewiſe be conſtructed with an upright front of glaſs, head high, and a ſloping roof of glaſs-work, ranging from the upright front to the top of the back wall, which is the moſt eligible form, both for convenience and benefit of the plants; either of which conſtructions may be erected detached, or againſt a ſouth wall already built, which will ſerve for the back, and ſave ſome expence; the ends may either be of wood or brick, and ſhould be glazed like the front, &c. and the glaſs-work in every part be made to move on and off, as well as to ſlide backward and forward to give air, and perform other neceſſary work. At one end, near the back-wall, a door ſhould be made to enter occaſionally at, and within-ſide a pit formed for the bark-bed, three feet deep, partly ſunk, but the greater part raiſed, being continued the whole length and width, except about a foot and a half of alley to paſs in, to perform the neceſſary culture, as well as view and gather the produce of the different plants, &c.

The pit within is to be filled with new bark or tan, in order to afford a proper heat for the growth and ſupport of the plants that are to be cultivated in the frame. See HOT-*bed*.

The frame where fire-heat is to be employed muſt be formed of brick-work; at leaſt the back or main wall, for the convenience of having fire-flues, and the whole front, &c. be glaſs, like the other ſorts; the length may be from twenty to forty or fifty feet, or more, though one fire will not warm more than that length; the width from five or ſix to twelve or fifteen feet, and eight or ten in height. In this caſe the fire is burned in a furnace ſet up behind, at one end, or in the middle, thence communicating the heat by internal flues or funnels running the whole length of the back wall in three or four returns one above another, and continued in one or two flues in the front. And frames, thus conſtructed, may be contrived, either of moderate width, for one row of trees only, to range againſt the back wall, or may be made capacious enough to have a range of trained wall-trees behind, and ſome ſmall half, or full ſtandards, ranging alſo from the back to the front; or be entirely for ſtandards, eſpecially thoſe of cherry kinds.

Where it is intended to have a narrow frame, for only a row of trained trees behind, the width of from four to five or ſix feet is ſufficient, having the back or main wall formed of brick or ſtone, as juſt obſerved, eight or ten feet in height, with ſeveral flues within-ſide, returned over each other, running the whole length of the wall; in the front muſt be a low wall a foot in height, on which to lay a plate of timber, and from which are ranged glaſs frames, or lights in one continued ſlope to the top of the back wall, there received into a proper frame-work; but for the greater convenience, the lights may be in two tiers or ranges, an under and upper tier, the upper range being made to ſlide up and down over the others, but ſo that all the glaſs-work can be moved away occaſionally, to admit full air to the trees after the work of forcing is over: the whole of the bottom-ſpace within the frame ſhould be of good loamy earth, or any good garden-mould, two ſpades deep, which ſhould be dug or trenched in the common way; then a range of trees planted behind, towards the wall, two or three yards aſunder, erecting a trellis behind them, upon which to train the branches, as againſt a wall or eſpalier. Other inferior plants may likewiſe be ſet in the border or in pots, in front of the trees in the frame.

In moſt forcing frames of this conſtruction, from forty to fifty feet length may be ſufficient; but if they be made longer, two furnaces for fires are neceſſary to heat them properly. See HOT-*Houſe*.

Several different ſorts of frames of this nature may be ſeen in the appropriate plate.

With the firſt ſort of forcing-frame, various kinds of fruits may be produced, both of the dwarf-fruit-tree and other kinds, as well as different ſorts of vegetables and plants of the flowery and other kinds. And frames of this ſort may have ſuch dimenſions as to have ſubſtantial hot-beds prepared within them, for the purpoſe of receiving many different ſorts of potted plants.

But in the ſecond ſort of frame, from the heat being more regular and laſting, a ſtill greater variety of the finer ſorts of fruits, and the more tender flowers and other vegetable productions may be produced, not only long before they could be raiſed in any other way, but with much greater eaſe and convenience, as well as with greater certainty and ſucceſs.

And the laſt kind of forcing-frame is moſtly employed in furniſhing many of the finer ſorts of fruits, that require higher degrees of heat to procure them in the utmoſt perfection, than could otherwiſe be obtained; ſuch as pine-apples, grapes, peaches, nectarines, and various others, as well as many tender ſorts of vegetables, and numerous plants of the curious flower and other kinds. See HOT-*Houſe*.

FORCING-*ground*, the ſpace or portion of ground in a garden that is deſtined to the purpoſe of forcing or raiſing vegetable productions by means of artificial heat. Grounds of this ſort ſhould always be detached from the garden, and ſituated as near to the ſtable as the nature of the land will admit, in order that dung may be conveyed to them with

with as much eaſe and convenience as poſſible, litter prevented, and the diſagreeable appearance of the beds concealed from the ſight.

It is eſſentially neceſſary in moſt ſituations, and particularly in ſuch as are expoſed, to have theſe grounds incloſed with a fence, either of brick-work or paling, ſix or eight feet in height. They ſhould have ſufficient ſpace for containing a ſuitable number of frames and pits, and ſuch linings as may be neceſſary in the working of them. And it is of great advantage in raiſing many ſorts of tender crops, both of the vegetable and fruit kind, to have four or ſix-feet borders made round them in a raiſed manner; as in ſuch ſituations much ſhelter and warmth are afforded.

In caſes where melons are raiſed, it is uſual to have brick pits coped with ſtone or wood. Thoſe which are moſt convenient, according to Mr. Forſyth, are ſuch as are about twelve feet in width and two and a half in depth; the length in proportion to the number of frames employed. They are, however, often made of much ſmaller dimenſions, eſpecially where the extent of forcing-ground is but ſmall and limited. With regard to the ſize of the lights for early melons, the above author adviſes, that they ſhould be five feet in length and three in breadth; and for others, ſix feet in length and four in breadth, the former being four and the latter three light boxes. See FRAME, *Garden*.

It is found that in conſtructing the pits, nine-inch walls will be ſufficient, ſquare pieces of wood being built in the upper parts of them, where wood copings are made uſe of to nail them to. As wood decays rapidly, ſtone ſhould be preferred. Sometimes the walls are not built ſolid, but ſquare openings left, ſo as to admit the heat from the outſides, as ſhewn in the plate on forcing-frames.

It is directed by Mr. Forſyth, that there ſhould be a track or walk between the ridges of about ſix or ſeven feet in breadth, ſufficient to admit a cart to carry dung, as being more expeditious than wheeling it in. This walk ſhould be made up as high as the coping, and ſloping gently towards each end, being laid in the bottom with brick-rubbiſh, and covered over with ſea-coal aſhes or ſand. By this means, after the linings are made up, it may be kept perfectly neat and clean. A looſe drain will likewiſe be néceſſary in the middle of the bottom of the pit, for conveying off wet and the oozing from the dung, to a tank or ciſtern conſtructed for its reception. The fluid thus collected may be made uſe of in watering cabbage and other plants of the ſame kind in the kitchen garden.

FORCING-*pit*, a ſort of pit conſtructed of brick-work, with fire-flues, in various ways, according to circumſtances, for the purpoſe of making tan or other ſorts of hot-beds, and being covered with glaſs frames.

This ſort of pit is uſeful for receiving different ſorts of tender potted plants which require conſiderable degrees of heat in their cultivation and growth. See BARK-*pit*.

FORCING-*wall*, a wall conſtructed with flues for the purpoſe of conveying and communicating fire-heat, in order to ripen, at an earlier period than uſual, various kinds of tree-fruits that are planted and trained againſt it; and which are protected in the front by glazed frames fixed againſt it. See HOT-*wall*.

Walls of this ſort ſhould always be erected in warm ſheltered ſituations, and have ſouthern aſpects, in order that they may derive the greateſt poſſible advantage from the genial heat and influence of the ſun and air.

FORCING *Pump*. See PUMP.

FORCKENDORP, in *Geography*, a town of Germany, in the principality of Bayreuth; 4 miles S.S.W. of Bayreuth.

FORCULUS, *quaſi à Foribus*, in *Mythology*, a divinity who preſided over the gates of houſes.

FORD'S ISLAND, in *Geography*, a ſmall iſland in the Atlantic, near the coaſt of South Carolina. N. lat. 33° 14′. W. long. 79° 5′.

FORDEN, a town of Germany, in the biſhopric of Bamberg; 7 miles E.S.E. of Weiſchenfeld.

FORDERGERSDORF, a town of Germany, in the circle of Erzgeburg; 9 miles E.N.E. of Freyberg.

FORDICIDIA, or FORDICALIA, in *Antiquity*, a religious feaſt, among the Romans, held on the fifteenth of April; thus called from the Latin, *forda*, a cow big with calf; and *cædo*, I ſlay, or ſacrifice; becauſe ſuch cows were herein ſacrificed to the goddeſs Tellus, or the earth.

Forda, a cow with calf, is formed, according to Ovid, from *fero*, I bear; or rather, as Scaliger and Salmaſius imagine, from the Greek φοραϛ, φοραδοϛ, the ſame.

Varro writes, that there were ſeveral of theſe cows ſacrificed in the Curiæ. And Livy and Halicarnaſſeus relate, that there was one in each Curia; ſo that there were thirty in all; which is confirmed by Ovid. Faſtor. lib. i. ver. 631.

The fordicidia were firſt inſtituted by Numa, on occaſion of a general barrenneſs among the cattle. Ovid gives a particular deſcription of the ceremony, in the paſſage above quoted; he adds, that part of theſe cows were ſacrificed in the temple of Jupiter; that is, in the Capitol.

FORDINGBRIDGE, in *Geography*, a market town, which gives the name to the hundred in the diviſion of New Foreſt weſt, in the county of Hants, is pleaſantly ſituated on the banks of the river Avon, over which there is a good ſtone bridge of ſeven arches, and on the weſtern verge of the foreſt. The place is noticed as having two mills, and a *church* at the time of the Norman ſurvey. Formerly it appears to have been much larger than it now is; and its preſent diminutive ſize is attributed to frequent fires, by which at times it has ſeverely ſuffered. From the returns under the population act in 1801, the number of houſes was 461, containing 2335 inhabitants; of whom 892 are reported as occupied in trade, principally in calico-printing, and the fabrication of bed-ticking. Here is alſo a ſmall manufacture of checked linens. The town is governed by a conſtable, choſen annually at the court leet, held by the lord of the manor; and the weekly market is kept on Fridays. From its adjacency to the romantic ſcenery of the foreſt, it has to boaſt of numerous and handſome ſeats in its vicinity. See Beauties of England and Wales, and Gilpin's Obſervations on the Coaſts of Hants, &c.

FORDINGIANO, a town of the iſland of Sardinia; 22 miles S.E. of Boſa.

FORDOUN, or FORDUN, a pariſh in Kincardineſhire, forming part of the far-famed vale of Strathmore, contains the villages of Auchinblæ and Kincardine; the latter of which gives name to the county, and was long the principal town, till James VI. removed the courts of juſtice to Stonehaven; ſince whoſe reign, that has continued to be the county town. In this pariſh are the veſtiges of a large Roman encampment, and the ruins of an antiquated caſtle, ſuppoſed to have been a royal palace, and once the reſidence of Kenneth III. a prince diſtinguiſhed in Scottiſh hiſtory. By the returns made to government in 1801, Fordoun contained 465 houſes and 2225 inhabitants, 909 of whom were reported as employed in trade and agriculture.

At Auchinblæ was born the celebrated philologiſt and philoſopher, lord Monboddo, well known in the literary world by his knowledge of the Greek language, and the intimate acquaintance he poſſeſſed with the writings of the ancients.

ancients. His "Origin and Progreſs of Language," in ſix volumes, 8vo. contains a ſingular ſyſtem, which ſuppoſes all words to be derived from certain primitive *monads*, compoſed of vowel diphthongs. The "Hiſtory of ancient metaphyſics," in ſix volumes, quarto, contains opinions equally novel or eccentric. Fordoun alſo was the native place, and gave the name to

FORDOUN, JOHANNES DE, in *Biography*, a celebrated Scottiſh hiſtorian, who flouriſhed in the fourteenth century. His work, entitled "Scotichronicon," after all the attacks which have been made upon it by various writers, and the ridiculous light it was held up by Buchanan, is ſtill the moſt complete and authentic hiſtory extant of the early affairs of Scotland. Like many other excellent writers, in the early and middle ages of the annals of this iſland, Fordoun has had great injuſtice done him by continuators and tranſcribers. Bowyer, his diſciple and friend, it has now been aſcertained, was the author of ſome of the books long aſcribed to Fordoun; and many interpolations and additions totally irrelevant, or contradictory to the tenor of the original work, are attributable to the ſame prolific ſource of unfounded or unſupported narrative. An edition of his works was publiſhed in folio, by Goodal, at Edinburgh; but the beſt, collated with numerous manuſcripts, is one in ſix volumes, royal 8vo. with a preface by Hearne, printed at Oxford. See Gen. Biog. Dict. and Hearne's Prefatio.

FORDSAND, in *Geography*, a ſmall iſland of Denmark, near the coaſt of Sleſwick, in the German ocean. N. lat. 55° 1′. E. long. 8° 35′.

FORDWICH, a town of England, in the county of Kent, ſeated on the Stour; appearing to be a mean village, but governed by a mayor and jurats. It is a member of the town and port of Sandwich, and enjoys the ſame privileges as the Cinque Ports. The river is navigable for ſmall veſſels; four miles N.E. of Canterbury, and 60 E. of London.

FORDYCE, DAVID, in *Biography*, was born at Aberdeen in the year 1711, where he received his education, firſt in the grammar ſchool, and then at Mariſchal college, where he made great proficiency in the Greek language, in philoſophy, and in the mathematics. In 1728, when he was but ſeventeen years of age, he was admitted to the degree of maſter of arts. He next applied himſelf to divinity, which he cultivated with peculiar ardour, and was licenſed as a preacher, but never undertook the charge of a congregation in his native country. For ſome time he officiated as domeſtic chaplain to John Hopkins, eſq. of Britons, near Rumford, Eſſex, who had a regular ſervice every Sunday in the chapel at his own houſe. In the year 1742 he was choſen profeſſor of philoſophy in the Mariſchal college at Aberdeen. Here he read lectures on natural hiſtory, chronology, Greek and Roman antiquities, and on the ſeveral branches of natural and experimental philoſophy. In 1745 and 1748 he publiſhed his "Dialogues concerning Education;" which, though by no means a ſyſtematic treatiſe on the ſubject, contain diſcuſſions of the principal points relative to education, as alſo of various queſtions on ſubjects of taſte and polite literature. He was author of the treatiſe on moral philoſophy contained in the Preceptor, which was afterwards given to the world in a diſtinct volume, 12mo., and has ſince paſſed through ſeveral editions. In the year 1750 he made a tour on the continent, with a particular view to examine the remains of ancient art at Rome, and in the following year he meant to return to his native country, but was ſhipwrecked and loſt his life in a ſtorm on the coaſt of Holland. Thus ended the career of a man who had excited the higheſt expectations of the future benefits to be derived from his talents and learning; he had reached only his forty-firſt year. His brother James publiſhed, from a manuſcript left behind him, his "Theodorus, a dialogue concerning education." In ſpeaking of this work, a contemporary writer obſerved, "that the piety of the writer appears to have been manly and rational; his ſentiments of the divine perfections exalted and amiable; his knowledge of human nature, and of the various ways of touching the human heart, very extenſive; and his eloquence natural and affecting." This dialogue has been repeatedly reprinted, and in every edition, excepting the firſt, has been joined with Dr. Fordyce's ſermon on the eloquence, and his eſſay on the action proper for the pulpit. Another poſthumous work of Mr. Fordyce was "The Temple of Virtue, a Dream;" it was publiſhed by his brother in 1757, who added to the deſcriptive part twelve characters that had a claim to a place in it. Gen. Biog.

FORDYCE, JAMES, younger brother of the preceding, was born at Aberdeen in 1720. He received his claſſical education at the public grammar ſchool, and purſued the ſtudies neceſſary for a miniſter of the goſpel at Mariſchal college. His firſt appointment was to the place of ſecond miniſter in the collegiate church of Brechin, in the county of Angus. After continuing there ſome years, he accepted a call to Alloa, near Stirling. The people of this pariſh were prepoſſeſſed in favour of another, to the prejudice of Mr. Fordyce, yet by his impreſſive delivery, and indefatigable attention to every part of his miniſterial duty, he ſoon changed their prejudice into eſteem, and their eſteem into admiration. During his reſidence at Alloa he attracted public notice by the publication of three excellent ſermons, "On the Eloquence of the Pulpit;" "On the Method of promoting Edification by Public Inſtitutions;" and "On the deluſive and bloody Spirit of Popery." But a ſtill greater attention was excited by another ſermon, "On the Folly, Infamy, and Miſery of unlawful Pleaſure," which he preached before the general aſſembly of the church of Scotland in the year 1760. This diſcourſe contains ſuch maſterly compoſition, with reſpect to deſcription, ſpirit, and elegance, and was delivered with ſo much ſolemnity, animation, and feeling, that it is ſaid to have filled his learned fathers and brethren with aſtoniſhment, and juſtly raiſed him to unrivalled eminence among his clerical contemporaries. It was about this time that the degree of doctor of divinity was conferred upon him by the univerſity of Glaſgow; and in a ſhort time after, while he was on a viſit at London, he was invited to become copaſtor with Dr. Lawrence, to a reſpectable congregation of diſſenters at Monkwell-ſtreet. He accepted the offer, and on the death of his colleague, which happened in a few months, he was elected to the ſole paſtoral office. In this ſituation Dr. Fordyce maintained a high ſhare of popularity, generally preaching to crowded and overflowing audiences. To this he had a juſt claim, as well from the elegance of his compoſitions, as from the happy tendency that his diſcourſes had to impreſs the heart with the love of virtue and religion. He lived, however, to ſee a great declenſion in his popularity, for which many cauſes have been aſſigned, and they all had a ſhare in producing it. In the year 1772 a circumſtance took place which contributed greatly to thin the pews of his auditory. His brother, a banker of very extenſive buſineſs, was obliged to ſtop payment, and his ruin involved the fortunes and property of many of the doctor's conſtant hearers and moſt liberal ſupporters; and though no blame could attach to him on account of his brother's miſconduct,

yet the odium which it brought on his family did certainly operate unfavourably on the attachment of ſeveral other individuals to him as their miniſter. Another cauſe, which led to the decline of Dr. Fordyce's congregation, was a diſpute which took place between the doctor and Mr. Toller, his colleague: a number of perſons conceiving the latter to be much injured, withdrew with him to another place of worſhip. This was in the year 1775, but Dr. Fordyce diſcharged the duties at Monkwell-ſtreet till about Chriſtmas 1782, when he diſcontinued his public ſervices. In the following year he delivered "A Charge" at the ordination of his worthy and excellent ſucceſſor Mr., now Dr. Lindſay, which has been regarded as the fineſt ſpecimen of pulpit oratory which he had ever exhibited, and which certainly merits the attentive peruſal of every clergyman. He ſpent the remainder of his life chiefly in Hampſhire, in the vicinity of the earl of Bute, with whom he lived in great intimacy, and to whoſe valuable library he had conſtant acceſs. Towards the cloſe of life he went to Bath, where he died October 1ſt, 1796, in the 76th year of his age. The doctor's writings diſcover much genius and imagination, a correct taſte, extenſive knowledge of the world, and a happy method of engaging the attention; ardent piety, and a zeal for the intereſts of genuine virtue. His religious ſentiments were manly and rational; in private life he was highly amiable, and juſtly beloved by all who knew him. Beſides the pieces already noticed, he was the author of "Sermons to Young Women," in two volumes, which have been very generally read; "A Sermon on the Character and Conduct of the Female Sex;" "Addreſſes to Young Men;" "Addreſſes to the Deity;" a volume of "Poems;" and a "Diſcourſe on Pain." Ency. Brit. Dr. Lindſay's Funeral Sermon for Dr. Fordyce.

Fordyce, *Sir* William, knight, a phyſician of eminence, was the ſon, (and one of 20 children,) of Provoſt Fordyce of Aberdeen, where he was born in the year 1724. He received his education at the Mariſchal college of that place. At the age of eighteen he had finiſhed his academic ſtudies, and had diſtinguiſhed himſelf by his proficiency in Greek and mathematics, beſides acquiring a competent knowledge of phyſic and ſurgery, under the ableſt medical practitioner of Aberdeen. Thus prepared, he joined the army as a volunteer, and afterwards ſerved as ſurgeon to the brigade of guards on the coaſt of France, and in the German wars. The warm ſupport of his military friends co-operated with his own merit in early recommending him to extenſive practice in London; and he was ſent for to greater diſtances and received larger ſums in remuneration, than almoſt any phyſician of his time. He went to Switzerland, to Italy twice, to Scotland twice, and to other diſtant countries, to viſit ſome of his noble and wealthy patients. The wealth, which thus poured in upon him, he moſt liberally diſtributed in acts of friendſhip and bounty. Although he ſuffered ſeverely from the bankruptcy of his brother, Alexander Fordyce, a banker, he afterwards became bound for him, to the extent of ten thouſand pounds, in the project of a manufacture, which totally failed. And here we muſt not not omit a circumſtance, which equally redounds to the credit of ſir William, and of the gentlemen concerned. Sir William was called upon to pay this ſum in an hour, or go to gaol: when Mr. George Crawford, of Hertfordſhire, and Meſſrs. Drummond, generouſly diſcharged the debt, without requiring any other ſecurity than their confidence in ſir William's profeſſional merit, and in the determined integrity of his character. Yet, notwithſtanding theſe ſevere ſhocks to his fortune, he continued to maintain ſeveral poor families, and his generoſity to his relations was unbounded. His brother, the clergyman, author of the elegant and inſtructive ſermons to young women, had loſt ſeveral thouſand pounds by the banker's failure. Sir William immediately indemnified him to the full amount of his loſs. He wrote a treatiſe "on Fevers," and "on the Ulcerated Sore Throat," which contributed to extend his fame on his entering into practice: he likewiſe publiſhed "a treatiſe on the Venereal Diſeaſe." He ſuffered a long and ſevere illneſs, which terminated his life, on the fourth of December 1792, at his houſe, in Brook-ſtreet, Groſvenor-ſquare. See Gent. Mag. part ii. for 1792.

Fordyce, George, an eminent phyſician, was born at Aberdeen, on the 18th of Nov. 1736; after the death of his father, Mr. George Fordyce, who was proprietor of a ſmall landed eſtate, called Broadford, in the neighbourhood of that city. He was the only child of his parents, and, his mother having after no long time married again, he was taken from her, when about two years old, and ſent to Fouran, where he received his ſchool education. Thence he was removed to the univerſity of Aberdeen, where he took the degree of Maſter of Arts, when only fourteen years of age. Having very early formed a diſpoſition to the ſtudy of medicine, (which he uſed to attribute partly to the delight he had taken, in his childhood, in looking at the phials of coloured liquors in the windows of an apothecary's ſhop; and partly to his acquaintance with the learned Dr. Alexander Garden, then an apprentice to an apothecary in Aberdeen;) he was ſent, when about 15 years old, to his uncle, Dr. John Fordyce, who at that time practiſed medicine at Uppingham, in Northamptonſhire. With him he remained ſeveral years, and then went to the univerſity of Edinburgh, where, after a reſidence of three years, he obtained the degree of M. D. in October, 1758; having defended a theſis on catarrh. While he reſided at Edinburgh, Dr. Cullen was ſo much pleaſed with his diligence and ingenuity, that, beſides ſhewing him many other marks of regard, he frequently gave him private aſſiſtance in his ſtudies; of which kindneſs the pupil was ever grateful, and was accuſtomed to ſpeak of his preceptor in terms of the higheſt reſpect. About the end of the year 1758, he came to London; but ſoon afterwards went to Leyden, chiefly for the purpoſe of ſtudying anatomy, under Albinus. He returned to London in 1759, where he determined to fix himſelf as a teacher and practitioner of medicine; a determination, which was greatly diſapproved of by his relations, as the whole of his patrimony had been expended upon his education. Inſpired, however, with a confidence, which frequently attends the conſcious poſſeſſion of talents, he perſiſted in his purpoſe, and, before the end of 1759, commenced a courſe of lectures on chemiſtry: this was attended by nine pupils. In 1764 he began to lecture alſo upon the materia medica, and the practice of phyſic; and he continued to teach theſe three ſubjects for nearly thirty years, giving, for the moſt part, three courſes of lectures on each of them every year; a courſe which conſiſted of ſix lectures in the week of nearly an hour on each ſubject, laſting nearly four months. The time occupied by theſe lectures was from about ſeven o'clock in the morning till ten. In 1765 Dr. Fordyce was admitted a licentiate of the College of Phyſicians; and in 1770 he was choſen phyſician to St. Thomas's hoſpital, after a conſiderable conteſt with Dr., afterwards ſir William Watſon, whom he overcame by a majority of three, having 109 votes againſt 106. In 1774 he became a member of the Literary Club; in 1776 he was elected a fellow of the Royal Society; and in 1787

he was admitted, *ſpeciali gratia*, a fellow of the College of Phyſicians. This circumſtance evinces the high opinion of his abilities entertained by his profeſſional brethren: for as he had been particularly active in the diſpute, which had exiſted about twenty years before, between the fellows and licentiates, it was ſuppoſed that he had forfeited all title to be admitted into the fellowſhip through favour. But it is believed that the college, being at this time engaged in preparing a new edition of their "Pharmacopœia," wiſely ſuppreſſed their reſentment, in order to obtain the aſſiſtance of Dr. Fordyce in the proſecution of this work, there being confeſſedly none of their own number ſo well acquainted with pharmaceutical chemiſtry as himſelf. In 1793 he aſſiſted in forming a ſmall ſociety of phyſicians and ſurgeons, which has ſince publiſhed two uſeful volumes under the title of "Tranſactions of a Society for the Improvement of Medical and Chirurgical Knowledge;" and he continued to attend its meetings moſt punctually, until within a month or two of his death, which took place at his houſe in Eſſex-ſtreet, in the Strand, on the 25th of May, 1802.

His countenance was full and heavy, and not expreſſive of his powers of mind; and his manners were leſs refined, and his dreſs, in general, leſs ſtudied, than is uſually regarded, as becoming the phyſician in this country. From theſe cauſes, and from his ſpending a ſhort time with his patients, although ſufficient to enable him to form a juſt opinion of their diſorders, he had for many years but little private employment in his profeſſion; and never, even in the latter part of his life, when his reputation was at its height, enjoyed nearly ſo much as many of his cotemporaries. This may have partly reſulted too, from his fondneſs for the pleaſures of ſociety, to which he often ſacrificed the hours that ſhould have been dedicated to ſleep; he has frequently indeed been known, in his younger days, to lecture for three hours in a morning, without having undreſſed himſelf the preceding night. The vigour of his conſtitution enabled him to ſuſtain for a conſiderable time, without apparent injury, this debilitating mode of life: but at length he was attacked with the gout, which afterwards became irregular, and for many years frequently affected him with excruciating pains in his ſtomach and bowels: in the latter part of his life, alſo, his feet and ankles were almoſt conſtantly ſwollen, and a little time before his death he had ſymptoms of water in the cheſt. To the firſt mentioned diſeaſe (gout), he uniformly attributed his ſituation, which, for ſeveral weeks previous to his diſſolution, he knew to be hopeleſs.

Dr. G. Fordyce poſſeſſed a remarkably accurate and retentive memory, in which he placed ſuch great confidence, that he gave all his lectures without notes, and it is not known that he ever had any; nor did he make any memorandum in writing of the engagements, whether of buſineſs or pleaſure, which he formed; yet he was always moſt punctual in obſerving them. Even when he compoſed his works for publication, his materials were altogether drawn from ſtores in his memory, which had often been laid up there many years before. This, while it enables us to account for the extraordinary extent of his information in the ſciences, either immediately or remotely connected with medicine, alſo affords an explanation of his great deficiency in the art of literary compoſition and of the great want of arrangement, by which his writings are diſfigured. His ſtyle is commonly inelegant, and often involved, inaccurate, and obſcure: he frequently not only offends againſt the common rules of ſyntax, but errs even in reſpect to orthography; and his want of method led him to frequent repetitions. Theſe faults might, perhaps, have been avoided, had a leſs perfect memory led him, from his early years, to commit to writing the information which he wiſhed to preſerve.

Dr. Fordyce was the author of ſeveral publications, both on medical and philoſophical ſubjects. 1. "Elements of the Practice of Phyſic." This was uſed as a text-book for a part of his courſe of lectures on that ſubject, and was publiſhed in two parts, in 1768 and 1770, in 4to. 2. "Elements of Agriculture and Vegetation." He had given a courſe of lectures on this ſubject to ſome young men of rank, ſoon after the cloſe of which, one of his hearers, the late Mr. Stewart Mackenzie, preſented him with a copy of them from notes which he had taken. Dr. Fordyce corrected the copy, and afterwards publiſhed it in 1771, in 4to. 3. "A Treatiſe on the Digeſtion of Food," 8vo. 1791; which was originally read before the College of Phyſicians as the Gulſtonian lecture. 4. But the work on which he employed the moſt labour, was a ſeries of "Diſſertations on Fever," of which four were publiſhed during his life, and one left in manuſcript, which has ſince been printed. His other writings conſiſt of papers, which appeared in the Philoſophical Tranſactions of the Royal Society, and in the Tranſactions of the Society for the Improvement of Medical and Chirurgical Knowledge, upon the following ſubjects. In the former are eight papers: 1. On the Light produced by Inflammation. 2. Examination of various Ores in the Muſeum of Dr. W. Hunter. 3. A new Method of aſſaying Copper-ores. 4. An Account of ſome Experiments on the Loſs of Weight in Bodies on being melted or heated. 5. An Account of an Experiment on Heat. 6. The Croonian Lecture on Muſcular Motion. 7. On the Cauſe of the additional Weight which Metals acquire on being calcined. 8. Account of a new Pendulum, being the Bakerian Lecture. His three papers in the Tranſactions of the laſt-mentioned ſociety, are. 1. Obſervations on the Small-Pox, and on the Cauſes of Fever. 2. An attempt to improve the evidence of Medicine. 3. Some Obſervations on the Compoſition of Medicines. He was beſides the projector of the experiments in heated rooms; an account of which was given to the Royal Society by ſir Charles Blagden; and he was the author of many improvements in various arts connected with chemiſtry, on which he was frequently conſulted by manufacturers. See Gent. Mag. for June, 1802.

FORE, or Fowre, in *Geography*, a ſmall market-town, or, as Dr. Beaufort calls it, a miſerable village of the county of Weſtmeath, Ireland, near Lough Lene; formerly of ſo much importance as to give name to a barony, and return two members to parliament. The name is ſaid to ſignify "the town of books;" and it is ſuppoſed to have been formerly a ſeat of literature. It has at preſent the ruins of ſeveral religious buildings. It is 2 miles from Caſtle-Pollard, and about 71 N.W. from Dublin.

Fore, applied to a *Ship*, denotes all that part of a ſhip's frame and machinery which lies near the ſtem.

Fore *and aft*, is uſed for the whole ſhip's length, or from end to end.

Fore *Bowline* is the bowline of the fore-ſail.

Fore-*Caſtle of a Ship*, is a ſhort deck placed in the fore part of the ſhip, above the upper deck.

It is uſually terminated, both before and behind, by a breaſt-work in veſſels of war; the foremoſt end forming the top of the beak-head, and the hind-part reaching to the after-part of the fore-chains.

Fore-*Cat-harpings*, are thoſe that are uſed to brace in the upper part of the fore-ſhrouds. See Cat-*harpings*.

FORE-BAY *of a Lock*, on canals, is the breaſt or front wall. Caledonian Reports, 1806, p. 12.

FORECLOSED, in our *Ancient Law Books*, ſignifies barred, ſhut out, or excluded for ever; as, when the equity of redemption on mortgages is barred. See EQUITY *of Redemption*, and MORTGAGE.

FOREFANG, or FOREFENG, in our *Old Writers*, is the taking of proviſion from any one in fairs or markets, before the king's purveyors are ſerved with neceſſaries for him. The word is Saxon, compounded of *fore*, *ante*, and *fangen*, *prendere*.

FOREFIELD, in *Mining*, ſignifies the face or further part of the work from the mouth or drawing-ſhaft of a mine. Sometimes this is called the ſtool or bank.

FORE-FLANK, the name of a point in cattle ſtock.

FORE-FOOT, in the *Sea-Language*, is when one veſſel ſails or lies acroſs another's way.

As if two ſhips being under ſail, and in ken of one another, one of them lies in a courſe, with her ſtern ſo much weather of the other, that if both hold on, the windward ſhip will run a-head of the other: ſuch ſhip is ſaid to lie with the other's fore-foot.

Though, as ſoon as ſhe has paſſed, they ſay, ſhe is gone out a-head.

FORE-FOOT *of a Ship*, is a piece of timber that terminates the keel at the fore end. It is connected by a ſcarf to the extremity of the keel, of which it makes a part; and the other end of it, which is bent upwards into a kind of knee or crotch, is faſtened to the lower end of the ſtem, of which it makes a part, being alſo called the gripe.

FOREGAVEL, FORGABULUM, in our *Old Writers*, is uſed for a ſmall reſerved rent in money, or quit-rent.

FOREGOERS. The king's ſurveyors were thus called from their *going before*, to provide for his houſehold. 36 Edw. III 5.

FORE-HAND, a term which, in reſpect to the horſe, ſignifies that part which is before the rider. Thus a horſe is often ſaid to have a good or bad fore-hand.

FORE-HAND *Rent*, in *Rural Economy*, is ſuch as is paid before entering upon, or deriving profit from a farm, or any thing held in tenure.

FOREHEAD, a point in the horſe, which ſignifies the front part of the head. The well-ſhaped forehead ſhould be ſomewhat broad, and rather flat: if with a feather and ſtar in it, it is the more complete.

FOREHEAD, *Wounds of*. See WOUNDS.

FORE-HOOKS *of a Ship*. See BREAST-*Hooks*.

FORE-JEERS. See JEERS.

FORE-JEER-*Bits*, in a *Ship*. See BITS.

FOREIGN, ſomething extraneous, or that comes from abroad.

The word is formed from the Latin *fores*, doors; or *foris*, out of doors; or *forum*, market, &c.

Foreign miniſter, foreign prince, foreign goods, &c. are thoſe belonging to other nations. See MINISTER, &c.

Foreign to the purpoſe, ſignifies a thing remote or impertinent.

Foreign plants are particularly called exotics. Foreign foſſils, ſee FOSSIL. Foreign motion, ſee MOTION. Foreign canons, ſee CANON.

In ſome univerſities they give the appellation foreign doctors, *doctores forenſes*, to ſuch as do not reſide in the place, or the univerſity; but take degrees to go and live elſewhere, and in other countries.

In the life of St. Paul, biſhop of Verdun, written by an anonymous author, and publiſhed from a MS. about four hundred years old, by Bollandus, we meet with *forenſis presbyter*, for a prieſt who lives in another part. The ſame Bollandus notes, that St. Ambroſe uſes the word *forenſis* for exterior.

FOREIGN is uſed, in *Law*, in ſeveral ſenſes, and joined with divers ſubſtantives. Thus,

FOREIGN *Anſwer*, is ſuch an anſwer as is not triable in the county where it is made.

FOREIGN *Attachment*. See ATTACHMENT.

FOREIGN *Bill of Exchange*. See BILL.

FOREIGN *Matter*, is matter triable in another county; or matter done in another county. See INDICTMENT.

FOREIGN *Oppoſer*, or *Appoſer*, is an officer in the exchequer, to whom all ſheriffs or bailiffs do repair to be appoſed by him of their green wax, after they are appoſed of their ſums out of the pipe-office; and who from thence draws down a charge upon one of them to the clerk of the pipe.

His buſineſs is to examine the ſheriff's eſtreats with the record, to aſk the ſheriff what he ſays to every particular ſum therein.

FOREIGN *Plea*, is a refuſal of the judge as incompetent, becauſe the matter in hand was not within his precinct.

FOREIGN *Seamen*, ſerving two years on board Britiſh ſhips, whether of war, trade, or privateers, during the time of war, ſhall be deemed natural born ſubjects. But the perſons ſo naturalized are not capable of being of the privy council, or members of parliament, or of taking any place of truſt, civil or military, or to have any grant from the crown of lands. Stat. 13 Geo. II. cap. 3. ſect. 2.

FOREIGN *Service*, is ſuch ſervice whereby a meſne lord holdeth of another, without the compaſs of his own fee: or that which a tenant performeth, either to his own lord or to the lord paramount, out of his own fee. Kitch. 299. Bract. l. ii. c. 16.

FOREIGN *Service* is alſo uſed to denote military ſervice performed to foreign ſtates. The ſtat. 3 Jac. I. cap. 4. makes it felony for any perſon to go out of the realm to ſerve any foreign prince or ſtate, without having firſt taken the oath of allegiance before his departure; and it is alſo felony for any gentleman, or perſon of higher degree, or who hath borne any office in the army, to go out of the realm to ſerve ſuch foreign prince or ſtate, without previouſly entering into a bond with two ſureties, not to be reconciled to the ſee of Rome, or enter into any conſpiracy againſt his natural ſovereign. And by ſtat. 9 Geo. II. cap. 30. enforced by 29 Geo. II. cap. 17. if any ſubject of Great Britain ſhall enliſt himſelf, or any perſon ſhall procure him to be enliſted, in any foreign ſervice, or detain or embark him for that purpoſe, without licence under the king's ſign-manual, he ſhall be guilty of felony without benefit of clergy; but if the perſon ſo enliſted or enticed, diſcover his ſeducer within fifteen days, ſo that he may be apprehended and convicted of the ſame, he ſhall be indemnified. By ſtat. 29 Geo. II. cap. 17. to ſerve under the French king, as a military officer, is felony without benefit of clergy: and to enter into the Scotch brigade, in the Dutch ſervice, without previouſly taking the oaths of allegiance and abjuration, incurs a forfeiture of five hundred pounds.

FOREIGNERS are the natural born ſubjects of ſome foreign prince. (See ALIEN.) Foreigners reſiding ſeven years in the Britiſh plantations, without any longer abſence than two months at one time, and taking the oaths, are to be deemed natural born ſubjects. But, excepting Quakers and Jews, all other perſons muſt receive the ſacrament in ſome proteſtant or reformed congregation in Great Britain,

or the colonies; a certificate whereof muſt be produced at the time of taking the oaths. 13 Geo. II. cap. 7. ſect. 2. See NATURALIZATION.

FOREIRO, FRANCIS, in *Biography*, a native of Liſbon, who flouriſhed in the ſixteenth century, was patronized by John III. king of Portugal, who ſent him to ſtudy at the univerſity of Paris. Here he became a perfect maſter of the dead languages; and on his return home, in 1540, he undertook the education of Anthony, prior of Crato, and became the moſt celebrated preacher in Portugal. In the year 1561, the monarch ſent him as a divine to the council of Trent, where he acquired the admiration of the aſſembled fathers by his excellent pulpit talents. He alſo recommended himſelf to their reſpect by the capacity which he diſcovered for buſineſs; and which induced them to entruſt to his management different confidential negociations with the pope. Foreiro was afterwards one of three divines, ſelected by the council of Trent to draw up their catechiſm, which was publiſhed in the year 1566. He was likewiſe employed by them to reform the miſſal and Roman breviary. The king, however, commanded him to return to Portugal, which prevented him from accompliſhing the latter undertaking. He had not long been home before he was appointed prior of Liſbon; and in the year 1568, he was choſen provincial of his order. When the term of the laſt office was expired, he withdrew from public life to the convent of Almada, which he had built; and here he died in the year 1587. His works are a Latin verſion of the prophecy of Iſaiah, with a commentary; which was firſt printed at Venice, then at Antwerp, and afterwards inſerted in the fifth volume of the "Critici Sacri," publiſhed at London in the year 1660. He wrote commentaries, likewiſe, on the books of Job and the Pſalms, which are loſt. Moreri.

FOREJUDGED *the Court*, in *Law*, is when an officer or attorney of any court is baniſhed, or expelled the ſame, for ſome offence; or for not appearing to an action on a bill filed againſt him; in which latter caſe, he is not to be admitted to officiate, till he appear to the bill. Anno 2 Hen. IV. cap. 8.

He ſhall loſe his office, and be forejudged the court, &c. "Forejudicare, interdum eſt male judicare." Spel. See ATTORNEY.

FOREJUDGER ſignifies a judgment, whereby a man is deprived, or put by a thing in queſtion.

FORE-KNIGHT, in the *Sea-Language*, a piece of wood, carved in figure of a man's head, and faſt bolted to the beams upon the ſecond deck.

FORE-LAND, in *Embanking*, is the ſpace or land left between the embankment of a river or marſh and the ſtream or tide-way.

FORE-LAND, in *Fortification*, is a ſmall ſpace of ground between the wall of a place and the moat; called alſo *berme*, and *liziere*.

FORELAND, or *Foreneſs*, in *Geography*, a point of land jutting out into the ſea.

FORELAND, *North*, a promontory of England, on the N.E. extremity of the coaſt of Kent, on which a ſea-mark has been erected by the corporation of the Trinity-houſe, in which lights are exhibited every night; 3 miles N. of Ramſgate. N. lat. 51° 23′. E. long. 1° 17′.

FORELAND, *South*, a cape of England, on the E. coaſt of the county of Kent, between Dover and Deal, with a light-houſe. N. lat. 51° 8′. E. long. 1° 22′.

FORELAND, *Eaſt*, a cape on the W. coaſt of North America, on the eaſt ſide of Cook's inlet. N. lat. 60° 43′. E. long. 209° 19′.

FORELAND, *North*, a cape on the W. coaſt of North America, and weſt ſide of Cook's inlet, where the Ruſſians have a factory, with one large houſe, about 50 feet long and 24 wide, inhabited by about 19 Ruſſians. N. lat. 61° 4′. E. long. 209° 34′.

FORELAND, *South*, a cape on the W. coaſt of North America, in Cook's river. N. lat. 60° 50′. W. long. 151° 20′.—Alſo, a cape in Upper Canada, formerly called Point Palé, on the north ſhore of lake Erie, oppoſite to Landguard. On either ſide of the point there is good anchorage for veſſels. Near its extremity on the eaſt ſide is a pond, where boats may be ſecure from moſt winds.

FORELAND, *Weſt*, a cape on the W. coaſt of North America. on the weſt ſide of Cook's inlet. N. lat. 60° 42′. E. long. 209°.

FORE-LEGS, thoſe ſituated on the fore part of the cheſt, which ſhould be ſtraight, and well formed in the joints.

FORELLA, in *Ichthyology*, a name given by Figulus and others to the trout.

FORELOCKS, in a *Ship*, are little flat wedges, like pieces of iron, uſed at the ends of bolts, to keep them from flying out of the holes.

FORELOIN, among *Hunters*, is when a hound going before the reſt of the cry, meets chace, and goes away with it.

FORELOIN, a term denoting a point in cattle: See CATTLE, and LIVE STOCK.

FORE-MAST *of a Ship*, is a round large piece of timber, ſeated in her fore part, on which is borne the fore-ſail, and fore-top-ſail yard. See MAST.

FORE-MAST *Men*, in a *Man of War*, thoſe on board that take in the top-ſails, ſling the yards, furl the ſails, browſe, triſe, and take their turn at the helm, &c.

FORENSIC SERVICE. See SERVICE and FOREIGN.

FORENSIS TOGA. See TOGA.

FORENZA, in *Geography*, a town of Naples, in Baſilicata; 8 miles S. of Venoſa.

FORE-RAKE, in *Sea Language*. See RAKE.

FORE-REACH. The ſeamen ſay one ſhip fore-reaches upon another, when both ſailing together, ſhe ſails better, or outgoes the other.

FORE-SAIL, the ſail of the fore-maſt. See SAIL.

FORESCHOKE, DERELICTUM, anciently ſignified as much as *forſaken* in modern language.

It is eſpecially uſed in one of our ſtatutes for land or tenements ſeized by the lord, for want of ſervices due from the tenant; and ſo quietly held and poſſeſſed beyond a year and a day.

As if we ſhould ſay, that the tenant, who ſeeing his lands and tenements taken into the lord's hand, and poſſeſſed ſo long, takes not the courſe appointed by law to recover them, does, in due preſumption of law, diſavow or forſake all the right he has to them. In which caſe ſuch lands ſhall be called foreſchoke, ſays the ſtat. 10 Ed. II. cap. 1.

FORESHORTENING, in *Painting*, is the art of conveying to the mind the impreſſion of the entire length of an object, when it is repreſented as viewed in an oblique or receding poſition; in which caſe, the actual viſion of it is ſhortened in line on the receding ſide; *e. g.* a ſtick held with the end towards the obſerver appears ſhortened to the view, and that in a degree according to the angle under which its lengthened ſide is ſeen; the art of painting requires, that though thus preſented, it ſhould have in its repreſentation the appearance of poſſeſſing its utmoſt extent. Such a view

of

of an object is called a foreſhortened view; and the repreſentation, foreſhortening it.

Without a previous knowledge of the forms of bodies, no foreſhortening, however well wrought, would produce the full effect deſired. Of this, the world in general are not aware, and when a foreſhortened view of an object is given, are apt to exclaim againſt its appearance as being ſhorter than nature; not recollecting, or never having obſerved, how much they are aſſiſted in the view of the real object by ſome ſlight motion either of it or of themſelves; and thus they frequently, without mercy, criticiſe works of art in this reſpect, when their own preſumption is the only thing blameable. The writer of this article, with much difficulty, perſuaded the late lord Thurlow, the acuteneſs of whoſe judgment is every where acknowledged, of the truth of this remark. His lordſhip would not be diſſuaded from the idea, that the forms of natural objects were at all times, when viſible, completely to be underſtood. He was convinced, only by being requeſted to decide the length of a ſtick which he had not previouſly ſeen, and which was then held with the end nearly direct before him; this he was unable to do, and of courſe confirmed the opinion he had oppoſed.

Foreſhortening conſtitutes the difficulty of deſigning or drawing. The forms of bodies, wherein lines are preſented direct before the view, as in ſquare-ſided ones ſeen immediately in front, are very eaſily imitated: but when thoſe compoſed of intricate lines are thrown into oblique poſitions, where every line varies in appearance from its real ſhape, yet the whole together gives the juſt idea of the body; then is the ſkill of the great artiſt required to repreſent it faithfully; and none but the moſt cultivated talent is equal to the taſk.

In the foreſhortening of ſtraight-ſided objects, the rules of perſpective, when aided by light and ſhade, will fully produce the effect; and indeed the recollection of them is at all times uſeful when foreſhortened views are ſelected for imitation: but the variations of rounded objects, and eſpecially if compoſed of many parts, are too numerous and complicated to be ſubmitted to the regulations of that ſcience; reaſon, and the eye alone, muſt then be the guides; as in the face and limbs of the human figure, which are conſtantly preſenting themſelves under foreſhortened views.

That would be of neceſſity a very ſtiff action of the figure indeed, in which ſome part or other was not affected by this peculiarity; a leg, or an arm, the neck, or ſome feature of the face. The mere receding of the trunk and limbs in their rounding is in fact a foreſhortening, in the moſt direct front view; and it requires great delicacy of the eye and hand to adjuſt the due proportions of the parts as they retire from the view: and to give the appearance of their real quantity where a much ſmaller one is actually ſeen; that is, occupies upon the retina of the eye a much ſmaller ſpace (owing to the obliquity of the view) than they would do if ſeen directly in front.

The variations that take place in the forms of bodies, as they are more or leſs foreſhortened, are perfectly aſtoniſhing to thoſe who are not accuſtomed to obſerve them. A lengthened object becomes ſquare, or almoſt a point; a round one, oval; and irregular ones take every form in turn; ſo that the ſkilful artiſt has by its means, when judiciouſly employed, the power of introducing figures according to his neceſſities, to fill his canvas, and complete the forms of his groups in whatever ſhape he pleaſes, without diſtortion of the limbs.

But when grace or beauty is required in drawings or paintings of the human figure, theſe foreſhortenings ſhould be ſparingly employed; for even when perfectly effected, they are ſtill apt to convey the impreſſion of bad proportion, and often produce unpleaſant forms.

The actual effect which takes place in foreſhortened views of objects that have projecting parts, is, that thoſe which are moſt in advance, by their projection, hide others that are behind them, and in immediate connection with them; and it is this loſs of parts which ſhortens the view: *e. g.* a horſe ſeen directly in front, is foreſhortened to the eye. The head projecting hides the neck, and the belly the hinder parts in ſome meaſure; yet, though thoſe parts are loſt to the view, by a previous knowledge of the form of the animal, and the turns of the lines that are ſeen indicating ſome intermediate form between thoſe preſented to the eye, the mind is at no loſs for the conception of its entire ſhape.

From this it is evident that the rules of proportion are but partially uſeful in foreſhortening, and therefore in drawing objects, thus preſented to the view, their viſible proportions muſt be copied, rather than thoſe proper and natural to them. For the eye and the underſtanding, being directed by the art of perſpective, ought to be the guide and meaſure in theſe kinds of effects.

Though this peculiar part of the art of drawing be conſtantly required by the painter more or leſs in all his works, it has been moſt principally exerciſed by thoſe who have been employed in painting cielings or domes; where the intention has frequently been, to make the whole of the objects of the picture foreſhortened, or appear, as the Italians term it, *ſotto in ſu* (as ſeen from below). Such is the caſe in great meaſure in the cieling of the banquetting room, now the chapel at Whitehall, painted by Rubens.

But the great exemplar of it is the dome of the great church at Parma, painted by that divine maſter Correggio; whoſe extraordinary talents appear to have revelled with delight in ſelecting the boldeſt and moſt extraordinary foreſhortenings of the human figure; in which he has ſucceeded moſt ſurpriſingly.

Tintoretto and Paulo Veroneſe, ſkilfully employed in adorning the cielings of the halls and chapels, &c. in Venice, choſe the *ſotto in ſu*, generally, as the mode of conſtruction for their pictures, and produced numberleſs aſtoniſhing works of this kind; and after them followed in the ſame way moſt of the maſters of the Venetian ſchool. It ſuited the ſtyle of that ſchool particularly; where freedom of execution, and brilliancy of colouring, produced by ſtrong contraſts of hues, and ſtrong oppoſitions of light and ſhadows, were by means of foreſhortenings readily brought into the ſurface of the picture. Sometimes it adds greatly to the grandeur of a figure to have it appear as ſeen a little from below, lowering the horizon by that means behind the figure; but it may be doubted whether that be owing to the lines produced by the foreſhortening, or to the comparatively increaſed maſs of figure againſt the ſky.

FORE-SHROUDS. See SHROUDS.

FORESKIN. See PREPUCE.

FOREST, SYLVA, in *Geography*, a great wood; or a large extent of ground covered with trees.

The word is formed of the Latin, *foreſta*, which firſt occurs in the Capitulars of Charlemagne, and which itſelf is derived from the German, *forſt*, ſignifying the ſame thing. Spelman derives it from the Latin *foris reſtat*, by reaſon foreſts are out of towns. Others derive *foreſta a feris*, q. d. *foreſta, quod ſit tuta ſtatio ferarum*, as being a ſafe ſtation, or abode, for wild beaſts.

The Caledonian and Hercynian foreſts are famous in hiſtory. The firſt was a celebrated retreat of the ancient Picts and

and Scots: the latter anciently poſſeſſed the greateſt part of Europe; particularly Germany, Poland, Hungary, &c. In Cæſar's time it extended from the borders of Alſatia and Switzerland to Tranſylvania, and was computed ſixty days journey long, and nine broad: ſome parts or cantons thereof are ſtill remaining. The foreſt of Dean, in Glouceſterſhire, is famous for its iron works. The ancients adored foreſts, and imagined a great part of their gods to reſide in them: temples were frequently built in the thickeſt foreſts, the gloom and ſilence of which naturally inſpired ſentiments of devotion, and turned men's thoughts within themſelves.

For the like reaſon, the ancient Druids made foreſts the place of their reſidence, and performed their ſacrifices, inſtructed their youth, and gave laws in them. See DRUIDS.

FOREST, in a *Law-ſenſe*, is defined a certain territory of woody grounds and fruitful paſtures, privileged for wild beaſts, and fowls of foreſt, chace, and warren, to reſt and abide in, under the protection of the king, for his recreation and delight; bounded with unremoveable marks and meres, either known by matter of record or preſcription; repleniſhed with wild beaſts of venery, or chace, and with great coverts of vert for ſuccour of the ſaid beaſts; for preſervation and continuance whereof, with the vert and veniſon, there are certain peculiar laws, privileges, and officers.

The properties and characters of a foreſt are, firſt, that it cannot be in the hands of any but the king; becauſe none elſe had power to conſtitute ſuch commiſſions as are neceſſary to the being of a foreſt, beſide the king; as, particularly, that of juſtice in eyre of the foreſt.

And yet the abbot of Witby had a foreſt by grant of king Henry II. and king John, with all officers incident thereto.

As the king reſerved to himſelf the foreſts for his own excluſive diverſion, ſo he granted out from time to time other tracts of land to his ſubjects, under the names of *chaces* or *parks* (which ſee), or gave them licences to make ſuch in their own grounds; which, indeed, are ſmaller foreſts, in the hands of a ſubject, but not governed by the foreſt-laws: and by the common law, no perſon is at liberty to take or kill any beaſts of chace, but ſuch as hath an ancient chace or park; unleſs they be alſo beaſts of prey. (See GAME.) If, however, the king grant a foreſt to a ſubject, and granteth further, that upon requeſt made in chancery, the grantee and his heirs ſhall have juſtices of the foreſt, then the ſubject hath a foreſt in law. 4 Inſt. 314. Cro. Jac. 155.

The ſecond character of a foreſt is the courts belonging to it, which are the *juſtice-ſeat*, and the *regard*, held every third year; the *ſwanimote* or *ſwainemote*, held thrice every year; and the *attachment*, once every forty days. See each reſpectively.

But the moſt eſſential mark of a foreſt is the ſwanimote, which is no leſs incident thereto than the court of pye-powder to a fair. If that fail, it ceaſes to be a foreſt, and commences a chace.

The third characteriſtic is the officers belonging to a foreſt, for preſervation of the vert and veniſon; as the juſtices of the foreſt, the warden, warder, or keeper, ranger, verderers, foreſters, agiſtors, regarders, bailiffs, beadles, &c. See each under its proper article, JUSTICE *of the Foreſt*, KEEPER, &c.

The beaſts of the foreſt are the following five, *viz.* the hart, hind, hare, boar, and wolf; the ſeaſons for hunting of which are as follow, *viz.* that of the hart and buck begins at the feaſt of St. John Baptiſt, and ends at Holy-rood day; of the hind and doe begins at Holy-rood, and continues till Candlemas; of the boar, from Chriſtmas to Candlemas; of the fox begins at Chriſtmas, and continues till Lady-day; of the hare, at Michaelmas, and laſts till Candlemas. Dyer, 169. 4 Inſt. 316.

The way of making a foreſt is thus: certain commiſſioners, appointed under the great ſeal, view the ground intended, and fence it round; this being reported in chancery, the king cauſes it to be proclaimed throughout the county where the land lies, that it is a foreſt, and is thenceforth to be governed by the laws of the foreſt; and prohibits all perſons from hunting there without his leave.

He then appoints officers for the preſervation of the vert and veniſon, and it then becomes a foreſt on record. Manwood. c. 2. Although the king may erect a foreſt on his own ground and waſtes; yet he may not do it on the lands of a ſubject, without his conſent; and agreement with him for that purpoſe ought to be confirmed by parliament. 4 Inſt. 300. Proof of a foreſt appears by matter of record, as by the eyres of the juſtices of the foreſts, and other courts, and officers of the foreſts, &c.; and not by the name in grants. 12 Rep. 22. As parks are incloſed with wall, paling, or other appropriate fence; ſo foreſts are incloſed by meres and bounds, ſuch as rivers, high-ways, hills; which are an incloſure in law, and without which it cannot be a foreſt: and in the eye of the law, "the boundaries of a foreſt go round about it, as it were a brick wall, directly in a right line from the one to the other, and they are known either by matter of record, or preſcription." 4 Inſt. 317. Bounds of a foreſt may be aſcertained by commiſſion from the lord chancellor; and commiſſioners, ſheriffs, officers of foreſts, &c. are empowered to make inqueſts thereof. Stat. 16 & 17 Car. I. c. 16. The boundaries of a foreſt are parcel of a foreſt; ſo that if any perſon kill or hunt any of the king's deer in any high-way, river, or other incluſive limit of a foreſt, the offence is the ſame as if committed within the foreſt. 4 Inſt. 318. There are two kinds of boundary: the one incluſive as to juriſdiction, ſuch as highways, &c.; the other excluſive in that reſpect, as churches, church-yards, mills, houſes, trees, &c. which bound the foreſt, but are not within the juriſdiction. Ibid. But a manor, land, wood, &c. within the meres of a foreſt, may, by the king's charter, be exempted out of the regard of the foreſt. (Manw. 133.) Yet it ſhall not be exempted by preſcription; for meres are eſtabliſhed by the ſtat. 6 Edw. I., and there can be no preſcription ſince. Jon. 271. By the grant of a foreſt, the game of the foreſt do paſs.

Foreſts are of ſo great antiquity in England, (except the New foreſt in Hampſhire, erected by William, called the Conqueror, and Hampton-court, erected by king Henry VIII. ſee ſtat. 31 Hen. VIII. c. 5.) that, it is ſaid, there are no records in hiſtory that mention their origin; though they are noticed by ſeveral writers, and in divers laws and ſtatutes. 4 Inſt. 319. The four principal foreſts are New, Sherwood, Dean, and Windſor foreſts. New Foreſt, ſo called from its being newly added to the ſeveral foreſts previouſly poſſeſſed by the crown, was afforeſted by William I. (the Conqueror); concerning which hiſtory informs us, that it was made by laying waſte a country of above 30 miles in extent, driving out all the inhabitants, deſtroying all their dwellings, not ſparing even their churches, 22, or as ſome ſay, 36 of which he demoliſhed, much as he affected a reſpect for religion. This was one of the moſt horrible acts of wanton cruelty recorded in hiſtory, if it was done for his pleaſure only; and there is no warrant in any ancient

ancient author for the conjecture of ſome modern writers, that he did it to facilitate the landing of forces, which he might have occaſion to bring over from Normandy, by thus diſabling the Engliſh from collecting together, or maintaining any on that coaſt. If this were his motive, and not the contiguity of the New foreſt to his palace at Wincheſter, it was the policy of a barbarous tyrant, not of a wiſe or good king. M. Voltaire, in his "Abridgment of Univerſal Hiſtory," has queſtioned this fact. But lord Lyttelton has alleged various proofs from Florence of Worceſter, William of Malmſbury, and other writers of the beſt authority in the times when they lived, which atteſt and eſtabliſh it. (Hiſt. Hen. II. vol. i. p. 380.) The chief officer of this foreſt is the lord warden: and under him are two diſtinct appointments of officers; the one to preſerve the *veniſon* of the foreſt, and the other to preſerve its *vert*: the former term, in the language of foreſt-law, comprehending every ſpecies of game; and the latter ſignifying every thing that bears a green leaf within a foreſt that may cover a deer, but eſpecially great and thick coverts. The office of ſuperintending the game is now delegated to 15 keepers, who preſide over the ſame number of walks, into which the foreſt is divided. The woods are under the ſuperintendence of the woodward, under whom are 12 regarders. Beſides theſe officers, who are appointed by the lord warden, there are four others called verderers, who are commonly gentlemen of property and intereſt in the neighbourhood, and are elected, like knights of the ſhire, by the freeholders of the county. Theſe officers are the only judges of the foreſt courts. There is another officer of late conſtitution, called the purveyor, and appointed by the commiſſioner of the dock-yard at Portſmouth, whoſe buſineſs it is to aſſign timber for the uſe of the navy.

The foreſt of Sherwood, ſo renowned in ſtory as the ſcene of the exploits aſcribed to Robin Hood, is a royal demeſne, and ſince the reign of Edward I. it has been always granted by the ſovereign to ſome of the nobility and gentry, as a mark of ſpecial favour. It is governed by a warden, his lieutenant, and a ſteward, a bow-bearer, and a ranger, four verderers, twelve regarders, four agiſtors, and twelve keepers in the main foreſt, under the chief foreſter, who holds it in fee, with liberty to deſtroy and kill at pleaſure, reſerving 100 deer in the whole walk. There are alſo, as members of the foreſt, ſeveral woodwards for every townſhip within the foreſt, and one for every principal wood.

Dean foreſt is now thinned by frequency of felling, and narrowed by increaſe of cultivation, though a few ſolitary deer ſtill continue to run wild in its receſſes.

Windſor foreſt is plentifully ſtocked with deer and game of every deſcription: it was appropriated to hunting, and the preſervation of royal game, by William the Conqueror; and the laws and regulations eſtabliſhed by him for that purpoſe are, in moſt reſpects, ſtill obſerved.

In England there are 69 foreſts, 13 chaces, and upwards of 750 parks.

The whole iſland was repleniſhed with all ſorts of game in the times of the Britons; they lived in a wild and paſtoral manner, without incloſing or improving their grounds, and derived much of their ſubſiſtence from the chace, which they all enjoyed in common. But when huſbandry took place under the Saxon government, and lands began to be cultivated, improved, and incloſed, the beaſts naturally fled into the woody and deſart tracts, which were called the foreſts; and, having never been diſpoſed of in the firſt diſtribution of lands, were therefore held to belong to the crown. Theſe were filled with great plenty of game, which our royal ſportſmen reſerved for their own diverſion, on pain of a pecuniary forfeiture for ſuch as interfered with their ſovereign. But every freeholder had the full liberty of ſporting upon his own territories, provided that he abſtained from the king's foreſts; as is fully expreſſed in the laws of Canute (c. 77.) and of Edward the Confeſſor (c. 36.); and this, indeed, was the ancient law of the Scandinavian continent, from whence Canute probably derived it; but, upon the Norman conqueſt, a new doctrine took place. Accordingly our ancient Norman kings, upon the principles of the feudal law, that the king is the ultimate proprietor of all the lands in the kingdom, and that therefore he has the right of the univerſal ſoil, were the firſt who incloſed foreſts, and ſettled the juriſdiction thereof. In the courſe of a few reigns from the Conqueſt, no leſs than ſixty-eight foreſts were incloſed: the ſtricteſt laws were made to ſecure them, and the ſevereſt penalties inflicted on all treſpaſſers upon them.

William the Conqueror decreed the eyes of any perſon to be pulled out, who took either a buck or boar; William Rufus made the ſtealing of a doe a hanging matter; the taking of a hare was fined 20*s.* and a coney at 10*s.* Eadmer adds, that fifty perſons of fortune, being apprehended by that laſt prince for killing his bucks, were forced to purge themſelves by the fire of ordeal, &c.

Henry I. made no diſtinction between him who killed a man, and him who killed a buck; and puniſhed thoſe who deſtroyed the game, though not in the foreſt, either by forfeiture of their goods, or loſs of limbs; though Henry II. remitted it for a temporary impriſonment.

Richard I. revived the old diſcipline of gelding and pulling out the eyes of thoſe convicted of hunting in the foreſt: but he afterwards relaxed a little, and was contented to make ſuch convicts abjure the realm, or be committed, or pay a fine. See FOREST-*Law*, infra.

FOREST, *Aſſize of the.* See ASSIZE.

FOREST, *Purlieu of a.* See PURLIEU.

FOREST, *Poſition of the.* See REPOSITION.

FOREST, *Waſte of the.* See WASTE.

FOREST is alſo uſed adjectively. The foreſt cities of the empire are four cities ſituate in the ancient Black foreſt, or Sylva Nigra, a part of the ancient Hercynian foreſt, *viz.* Rheinfield, Waldſhut, Seckingen, Lauffenbourg. But now, ſince the bounds of the Black foreſt are contracted, theſe cities are out of the limits thereof.

FOREST, *Black.* See BLACK *Foreſt.*

FOREST-*Law.* The foreſt-laws are peculiar laws, different from the common law of England.

Before the making of Charta de Foreſta, in the time of king John and his ſon Henry III., confirmed in parliament by 9 Hen. III. offences committed therein were puniſhed at the pleaſure of the king in the ſevereſt manner. By this charter many foreſts were diſafforeſted and ſtripped of their oppreſſive privileges, and regulations were made for the government of thoſe that remained; particularly, killing the king's deer was made no longer a capital offence, but only puniſhed by fine, impriſonment, or abjuration of the realm; yet even in the charter there were ſome grievous articles, which the clemency of later princes have ſince by ſtatute thought fit to alter *per aſſiſas* foreſtæ.

And to this day, in treſpaſſes relating to the foreſt, *voluntas reputabitur pro facto;* ſo that if a man be taken hunting a deer, he may be arreſted, as if he had taken a deer.

The foreſter may take and arreſt a man, if he be taken either at dog-draw, ſtable-ſtand, back-bear, or bloody-hand, notwithſtanding that three of theſe be only preſumptions. See Dog-*Draw*, Stable-*Stand*, &c. See alſo Black *Act*, Deer-*Stealing*, Game, &c.

Forest, a ſmall iſland in the Britiſh territories, at the mouth of lake Ontario, between which and Grand iſland is a narrow channel. It lies nine miles ſoutherly of fort Frontinac, and ſix N. weſterly of Roebuck iſland, in the ſame lake, and within the line of the United States.

Forests, or *Forêts, Department of*, one of the thirteen departments of the region of France, called the reunited country, and comprehending a part of the duchies of Luxembourg and of Bouillon, bounded on the eaſt by Sarre, and on the ſouth by Moſelle, in N. lat. 49° 55′. The territorial extent of this department is 7,080 kiliometres, or about 340 ſquare leagues, and it contains 225,549 inhabitants, in four diſtricts, *viz.* Neufchateau, Luxembourg, Bittbourg, and Dieckirch; 28 cantons, and 383 communes. Its contributions to general purpoſes amount to 1,340,663 francs, and the charges upon it for adminiſtration, juſtice, and public inſtruction, are 215,623 fr. 66 c. This department is hilly, wooded, indifferently fertile, and abounding in mines.

Forests, *Submerged*, in *Natural Hiſtory*, conſtitute a curious and important phenomenon, which moſt writers on the fens of the eaſtern coaſt of England have noticed: it being common in ſuch diſtricts to find proſtrate foreſts of trees under many feet of ſolid peat and ſilt, and even the tools, in ſome inſtances, which man, in the early periods of the hiſtory of this iſland, has employed in felling and converting them to his uſe; and this, in ſituations at preſent much below the high water level of every tide of the ſea, and ſcarcely elevated above low water level, in many inſtances, where no ſpecies of tree or plant of the kinds now found will grow, owing to the ſalt water, as obſerved under Encroachment *of the Sea*. In the Phil. Tranſ. 1799, part i. p. 145, Dr. Correa de Serra's ſurvey of a ſubmarine foreſt on the eaſt coaſt is given, and ſimilar ſubmerſions are obſervable on the flat ſhores of almoſt every maritime county of the Britiſh iſland: ſuch ſeem ſtrongly to point to one of two concluſions, *viz.* that the iſland has either ſubſided ſome feet into the boſom of the ocean within the laſt eight or ten centuries, or that the ſea has riſen as much within the ſame period, which latter phenomenon muſt have been obſerved on the oppoſite continent, in Denmark, France, and Spain, as well as the Netherlands, if it had occurred.

Forest *Trees*, in *Gardening*, is a common name for all ſuch trees as are grown in large woods and foreſts, either for the purpoſe of timber, or other uſes. Moſt of the deciduous trees are of this kind, and the term may be applied with propriety to many of the evergreen ſorts, as they are frequently introduced into large foreſt plantations. There are many different kinds of theſe trees; but thoſe chiefly raiſed as timber are oak, aſh, elm, beech, cheſnut, maple, birch, lime, alder, poplar, larch, fir, pine, &c.

The methods of raiſing foreſt-trees are different according to the ſeveral kinds, but principally by ſeeds, layers, and cuttings, as ſhewn under their different heads.

In the raiſing of plantations of foreſt-trees, either by ſowing the ſeeds of them, or ſetting the young plants after they have attained ſome growth, care ſhould conſtantly be taken to adapt the ſorts of the trees as much as poſſible to the ſtate and nature of the ſoil, as well as to the ſituation and expoſure of the land. In this way they ſucceed with much greater certainty and ſucceſs.

It is found by experience that the oak, elm, maple, birch, &c. ſucceed beſt on ſuch ſoils as are of the more deep and heavy kinds; while the aſh, beech, cheſnut, larch, fir, pine, &c. thrive the moſt perfectly in ſuch ſoils as are of the more light, dry, and friable deſcriptions; and the alder, poplar, willow, &c. where the moiſture is more conſiderable.

The proper management of foreſt-trees is a matter which requires much care and attention. They demand, in both thinning out and pruning their branches, the greateſt nicety and attention to the different circumſtances of the caſes. Where the climate is ſevere, and the expoſure conſiderable, much leſs thinning and pruning will be requiſite than under the contrary circumſtances. And in the latter operation, the nature and habits of growth of the trees are likewiſe to be taken into the account, and well conſidered, before the work is begun. In the buſineſs of thinning out foreſt-trees, where the ſituations are bleak and expoſed, great regard muſt alſo be had to the preſervation of ſuch ſorts of them, eſpecially near the outſides, as are the moſt ſuited to the nurſing and ſheltering of the others. Scarcely any thinning at all will be required in the more outward circles of foreſt-woods in ſuch ſituations. And in all caſes the work of thinning ſhould be performed in a gradual manner, ſo as not to cauſe too great a cold and expoſure at once to the trees.

Evergreen and reſinous trees in general ſtand in need of much leſs pruning than ſuch as are of the deciduous kind; indeed, till lately they have ſcarcely been attempted to be pruned at all; and how far the pruning ſyſtem which has recently been introduced, with reſpect to them, may be beneficial, is yet to be decided by the reſults of further trials. It has obviouſly one great diſadvantage, which is that of rendering the trees much leſs ornamental. It muſt be a very conſiderable increaſe in the growth of the timber of ſuch trees that can compenſate for ſuch a deficiency in their ornamental appearance.

The great object of pruning foreſt-trees is that of augmenting the growth of the wood or timber, by preventing their ſap-juice from being too greatly expended on the boughs or branches. But as it is neceſſary to the healthy growth and increaſe of ſuch trees that they ſhould poſſeſs a ſufficient number of ſuch branches, it is eaſy to perceive that the work of pruning may be carried too far, except this point be properly regarded in the execution of it. Proper pruning only requires that ſuch branches ſhould be removed as are ſuperfluous and unneceſſary to the perfect timber growth of the trees. Where length of bole is wanted, the lower boughs ſhould chiefly be trimmed off, thinning out at the ſame time a few in different parts of the head, which are placed in the moſt irregular or improper manner. But in caſes where the trees have been drawn up to a ſufficient length in the boles, the more irregular boughs of their heads need only be gradually thinned out, ſo as to promote their full growth and increaſe in wood. The branches ſhould in all caſes be cut off as cloſely and evenly as poſſible to the trees, and, to prevent the larger ones from ſplitting and doing injury in that way, they ſhould be cut on the under as well as upper ſide at the time they are removed or taken off from the trees.

By due attention in the pruning of trees, eſpecially when taken while they are young, their regular and ſtraight growths may be greatly directed and promoted. See Pruning *Timber Trees*.

All ſorts of foreſt-trees ſhould be well ſecured from being cropped while young by cattle, as, whenever a branch or ſhoot is taken off by them, the tree is in great danger of being wholly deſtroyed. It is the beſt method to remove ſuch injured ſhoots as ſoon as poſſible, by cutting them away cloſe to the bodies of the trees.

Beech, and ſome of the ſoft wooded trees, bear pruning

worſe than other ſorts, which ſhould be kept in mind by the workman employed in the execution of the buſineſs.

The moſt proper ſeaſon for pruning young trees of the foreſt kind is from February to the end of the following month, but they are often improperly pruned at other periods. And it ſhould be performed every ſecond or third year, according to the extent of growth, and the ſort of tree.

The growth of foreſt trees is extremely different according to the kind, ſoil, climate, expoſure, and various other circumſtances; but, in general, it may be from one inch to two inches in thickneſs in the boles, in the courſe of the year. And it is found that the large and ſmall trees increaſe in this reſpect pretty much in the ſame proportion where they are in equally thriving conditions. Mortimer long ſince, however, found that the ſtate and quality of the ſoil had much influence in this buſineſs; and after ſtating the common increaſe in the oak to be about one inch and a quarter in the body in the year, aſſerts that a large oak, which grew in one of his own ploughed fields, where the earth was tilled and manured every year, and that had often cattle lying under it, that dunged about its roots, grew annually no leſs than four inches in thickneſs. This is conſidered as a great proof of the advantage of digging about the roots of foreſt-trees and dunging them; and is ſuggeſted as a practical method of increaſing their growth in many caſes. The deſtruction of the weeds which riſe about foreſt-trees is likewiſe another method which is propoſed for increaſing their growth. The ſhrubby underwood in foreſts and coppices is, however, conſidered as highly beneficial in promoting the growth of the trees which they contain. It is probable, however, that the warmth cauſed by the cloſeneſs of ſuch woods may, in ſome meaſure, contribute to the effect. See PLANTATION, and PLANTING.

When foreſt-trees are tranſplanted, it ſhould be done while they are very young, as only of a few years growth, the ground having been previouſly well prepared for the purpoſe of receiving them. The oak, and other tap-rooted trees ſhould perhaps ſeldom, if ever, be tranſplanted where they are intended to ſtand for timber, as by ſuch means theſe roots are deſtroyed, and conſequently the natural habit of growth in them changed. See TRANSPLANTING *Timber-trees*.

FORE-STAFF, an inſtrument uſed at ſea, for taking the altitudes of heavenly bodies.

The fore-ſtaff, called alſo croſs-ſtaff, takes its denomination hence, that the obſerver, in uſing it, turns his face towards the object, in contradiſtinction to the back-ſtaff, where he turns his back to the object.

The fore, or croſs-ſtaff, repreſented in *Plate* I. *Navig. fig.* 7. conſiſts of a ſtraight ſquare ſtaff, A B, graduated like a line of tangents, and four croſſes or vanes, F F, E E, D D, C C, which ſlide thereon. The firſt and ſhorteſt of theſe vanes, F F, is called the ten-croſs, or vane, and belongs to that ſide of the inſtrument whereon the diviſions begin at three degrees and end at ten. The next longer vane, E E, is called the thirty-croſs, belonging to that ſide of the ſtaff wherein the diviſions begin at ten degrees, and end at thirty, called the thirty-ſcale. The next vane, D D, is called the ſixty-croſs, and belongs to the ſide where the diviſions begin at twenty degrees, and end at ſixty. The laſt and longeſt, C C, called the ninety-croſs, belongs to the ſide whereon the diviſions begin at thirty degrees and end at ninety.

FORE-STAFF, *uſe of the.* The great uſe of this inſtrument is to take the height of the ſun and ſtars, or the diſtance of two ſtars; and the ten, thirty, ſixty, or ninety croſſes, are to be uſed according as the altitude is greater or leſſer; that is, if the altitude be leſs than ten degrees, the ten-croſs is to be uſed; if above ten, but leſs than thirty, the thirty-croſs is to be uſed, &c.

Note, For altitudes greater than thirty degrees, this inſtrument is not ſo convenient as a quadrant or ſemi-circle.

FORE-STAFF, *to obſerve an altitude by the.* Apply the flat end of the ſtaff to your eye, and look at the upper end of the croſs for the centre of the ſun or ſtar, and at the lower end for the horizon. If you ſee the ſky, inſtead of the horizon, ſlide the croſs a little nearer the eye; and if you ſee the ſea, inſtead of the horizon, ſlide the croſs farther from the eye: and thus continue moving, till you ſee exactly the ſun or ſtar's centre by the top of the croſs, and the horizon by the bottom thereof.

Then the degrees and minutes, cut by the inner edge of the croſs upon the ſlide of the ſtaff, peculiar to the croſs you uſe, give the altitude of the ſun or ſtar.

If it be the meridian altitude you want, continue your obſervation as long as you find the altitude increaſe, ſtill moving the croſs nearer to the eye.

By ſubtracting the meridian altitude thus found, from ninety degrees, you will have the zenith diſtance.

To work accurately, an allowance muſt be made for the height of the eye above the ſurface of the ſea, *viz.* for one Engliſh foot, 1 minute; for five feet, $2\frac{1}{2}$; for ten feet, $3\frac{1}{2}$; for twenty feet, 5; for forty feet, 7, &c.

Theſe minutes, ſubtracted from the altitude obſerved, and added to the zenith diſtance obſerved, give the true altitude, and zenith diſtances.

FORE-STAFF. *To obſerve the diſtance of two ſtars, or the moon's diſtance from a ſtar, by the fore-ſtaff.* Apply the inſtrument to the eye, and looking to both ends of the croſs, move it nearer or farther from the eye, till you ſee the two ſtars; the one on the one end, and the other on the other end of the croſs; then the degrees and minutes cut by the croſs on the ſide proper to the vane in uſe, give the ſtar's diſtance.

FORESTAGE, FORESTAGIUM, in our *Ancient Cuſtoms*, an obſolete duty or ſervice, paid by the foreſter to the king. In Brittany, Lobineau obſerves, the office of foreſters was held by gentlemen of the firſt rank, who for their foreſtage were obliged to furniſh the lord, when he kept open houſe, with cups and ſpoons.

FORESTAGE alſo ſeems to have been uſed for a duty payable to the king's foreſters. "Ei ſint quieti de thelonio, et paſſagio, et de foreſtagio, &c." Chart. Edw. I.

It may likewiſe be taken for a right to uſe the foreſt, or a taking of reaſonable eſtovers.

FORESTAL, or FORSTAL, in Domeſday wrote *Foriſtel*, is an intercepting in the highway; or ſtopping, or even inſulting a paſſenger therein.

The word is formed of the Saxon *fore*, before, and *ſtal*, ſtation. In the laws of Henry I. the ſenſe of the word is thus explained: "foreſtal eſt, ſi quis ex tranſverſo incurrat, vel in viam expectet, et aſſaliet inimicum ſuum."

FORESTALLER, a perſon who buys up or foreſtalls the market of any articles of prime neceſſity; and who procures them on their way, or in the road to it.

FORESTALLING, the practice of buying up or bargaining largely for ſuch articles as are of the firſt neceſſity, as grain, fat cattle, ſheep, &c. in the way or paſſage before they reach the markets or fairs where they are to be ſold, with the view of enhancing their prices, in order to re-ſell them in the ſame places to a higher profit. Alſo the intercepting or procuring them as they come from beyond the ſeas or otherwiſe, towards any city, port, haven, or creek

of the kingdom. It has been ſtated by Fleta that it ſignifies "obſtructionem viæ vel impedimentum tranſitus, et fugæ averiorum."

It is a miſchievous practice which has long too much prevailed, and which ſeems at preſent far from being on the decline near large towns where the conſumption is great. It ſhould be guarded againſt as much as poſſible by a more full and complete enforcement of the laws againſt it.

By the 5th and 6th of Edw. VI. cap. 14. it is enacted that any buying or contracting for merchandize, victuals, or other things whatſoever, in the way, coming by land or water, to any fair or market, or to any port, &c. to be ſold, or cauſing the ſame to be bought; or diſſuading people by word, letter, or meſſage, or otherwiſe, from bringing ſuch things to market; or perſuading them to enhance the price after they are brought thither, is foreſtalling: and the party guilty of any offence of foreſtalling, &c. upon conviction at the quarter ſeſſions by two witneſſes, on bill, information, preſentment, &c. ſhall for the firſt offence loſe the goods ſo bought, or the value of them, and ſuffer two months impriſonment: for the ſecond offence, he ſhall forfeit double the value, and be impriſoned ſix months; and for the third offence, he ſhall loſe all his goods, be ſet up in the pillory, and be impriſoned at the king's pleaſure.

Several other ſtatutes have been made from time to time againſt the offences of foreſtalling, engroſſing, and regrating, all of which, from the 5 & 6 Edw. VI. c. 14. above cited, downwards, and all acts for enforcing the ſame, are repealed by ſtat. 12 Geo. III. c. 71, from the preamble of which we learn that the remedy was found worſe than the diſeaſe. But theſe offences againſt public trade are highly criminal at common law (1 Hawk. P. C. 234); and are puniſhable by diſcretionary fine and impriſonment. (Id. 235.) Indeed, ſo jealous is the common law of practices of this nature, which are a general inconvenience and prejudice to the people, and peculiarly oppreſſive to thoſe of the poorer claſs, that it will not ſuffer corn to be ſold in the ſheaf before it is thraſhed; for by ſuch ſale the market is in effect foreſtalled. 3 Inſt. 197. H. P. C. 152.

FORESTALLING is particularly uſed in Crompton, for ſtopping a deer broken out of the foreſt, and preventing its returning home again; or, a lying between him and the foreſt in the way he is to return.

FORESTEAD, in *Mining*, ſignifies a ſmall and inferior ſort of lead ore, obtained by buddling the old hillocks or refuſe of former ore-dreſſing; it is inferior to *ſmytham*, which ſee.

FORESTER, a ſworn officer of the foreſt, appointed by the king's letters patent to walk the foreſt, and watch the vert and veniſon; as alſo to attach and preſent all treſpaſſes againſt both, within his bailiwick or walk, to the foreſt-courts, to be puniſhed according to their offences. He is alſo to take care of the lawing of dogs.

Though the letters patent of a foreſter be ordinarily only granted *quamdiu bene ſe geſſerit*; yet they are granted to ſome and their heirs, who are hereby called foreſters in fee. 4. Inſt. 293. But though this office is a fee ſimple, it cannot be granted or aſſigned over without the king's licence. 4 Inſt. 316.

A "riding foreſter" is to lead the king in his hunting (1 Jones 277). Although every lord of parliament, ſent for by the king, may, both in coming and returning, kill a deer or two in the king's foreſt or chace through which he paſſes; yet it muſt not be done privily, without the view of the foreſter, if preſent; or, if abſent, by cauſing one to blow a horn; becauſe otherwiſe he may be a treſpaſſer, and ſeem to ſteal the deer. Chart. Foreſt. c. 11. 4 Inſt. 308. If any foreſter find any perſon hunting without warrant he is to arreſt his body, and carry him to priſon, from whence he ſhall not be delivered without ſpecial warrant from the king, or his juſtices of the foreſt, &c. But by ſtat. 1 Ed. III. c. 8. perſons are bailable, if not taken in *the manour*, as with a bow ready to ſhoot, carrying away deer killed, or ſmeared with blood: though if one be not thus taken, he may be attached by his goods. 4 Inſt. 289. A foreſter ſhall not be queſtioned for killing a treſpaſſer, who (after the peace cried to him) will not yield himſelf; ſo as it be not done out of ſome former malice. Stat. 21 Ed. I. ſt. 1. But if treſpaſſers in a foreſt, &c. kill a man who oppoſes them, although they bore no malice to the perſon killed, it is murder; becauſe they were upon an unlawful act, and therefore malice is implied. Rol. Abr. 548. And if murder be committed by ſuch treſpaſſers, all are principals. Kel. 87.

Sir William Temple relates, that the Franks having ſubdued all Gaul, their princes reduced Flanders into a kind of government, and gave the quality of foreſter, with part of the province, to the braveſt of their captains.

This quality of lord foreſter held till the time of Charlemagne, or, according to others, of Charles the Bald, in whoſe time Flanders being erected into a county, the title of foreſter was changed into that of count.

FORESTUS, PETRUS, or PETER VAN FOREEST, in *Biography*, was born at Alcmaer in 1522. He was ſent by his father to Louvain, in order to ſtudy with a view to the profeſſion of the law; which, however, he ſoon changed, on account of his ſtrong inclination to the profeſſion of medicine. This ſcience he cultivated in the univerſities of Bologna, Padua, and Rome; at the former of which he graduated, and afterwards proceeded to complete his ſtudies at Paris. He ſettled, at the requeſt of his friends, in his native town; but at the end of twelve years removed to Delft, in conſequence of a petition from the inhabitants of that place, which was at that time ravaged by a fatal contagious epidemic. Foreeſt obeyed the call of humanity, notwithſtanding the dangers to which he was neceſſarily expoſed. But he not only preſerved his own health, but was extremely ſucceſsful in his adminiſtration of remedies to others; inſomuch that the town of Delft regarded him as their preſerver, and retained him in the capacity of phyſician, with a conſiderable penſion, for nearly thirty years; after which he was invited to Leyden, to give the firſt lectures on medicine, at the opening of the univerſity in 1575. He afterwards returned to Delft, and reſided there about ten years more, when his attachment to his native city impelled him to viſit Alcmaer, where he terminated his life in 1597, in the ſeventy-fifth year of his age.

Foreſtus, (for by his Latin name he is beſt known,) was one of the moſt expert phyſicians of his time: he was extremely induſtrious, and his principal views were directed to the obſervation of diſeaſes, in which he manifeſted, in numerous inſtances, a conſiderable degree of penetration and judgment. Haller, indeed, has thrown out ſome ſuſpicions againſt the hiſtories of diſeaſe which he has detailed; and apprehends that he was occaſionally more anxious to prove the juſtneſs of his prognoſtics, and the felicity of his cures, than to relate a true account of the ſymptoms: but Boerhaave has praiſed him highly for the care and attention which he has evinced in the collection of ſo large a number of hiſtories of diſeaſe. The following are the titles of his works. 1. "Obſervationum et Curationum Medicinalium ſive Medicinæ Theoricæ et Practicæ, libri 28." Francofurti, 1602, two vols. in folio.

2. A third volume of the ſame work in 1604; and 3. A fourth volume, conſiſting of the 30th, 31ſt, and 32d books in 1607. 4. In 1610 a fifth volume was printed, under the title of "Obſervationum et Curationum Chirurgicarum, libri quinque. Acceſſerunt de incerto ac fallaci Urinarum judicio adverſus Uromentas et Uroſcopos, libri tres;" in which the fallacy and abſurdity of the pretenſions of the uroſcopiſts are clearly pointed out. 5. A ſixth and laſt volume of theſe treatiſes was publiſhed at Frankfort, in 1611, with the title of "Obſervationum et Curationum Chirurgicarum, libri quatuor poſterius," folio. All theſe books of obſervations were printed ſeparately at Leyden, between the years 1589 and 1610, in 8vo. The three books relative to the urine, in 1583. Complete collections of the works of Foreſtus have been ſubſequently publiſhed at various times and places.

FORE-THIGH, a term denoting the arm in the horſe and ſome other animals. It is a point not much attended to in neat cattle-ſtock.

FORE-TOP *of a Ship*. See TOP.

FORE-TOP-*Maſt* is half the length of the fore-maſt, and the fore-top-gallant-maſt half the length of the fore-top-maſt. See TOP-*maſt*, MAST, and SHIP.

FORE-TOOTH. Striking out the fore tooth is a mayhem.

FORE-YARD. See YARD.

FOREZ, in *Geography*, a country of France, ſo called before the revolution: it was a large and fertile valley interſected with ſmall rivers, which run into the Loire. The principal towns were Montbriſon and Roanne. The ſoil is fertile, but the air is not deemed wholeſome; it produces corn, hemp, excellent wine, cheſnuts, and other fruits. In ſeveral places are mines of coal and iron, and medicinal ſprings.

FORFANG. See FOREFANG.

FORFAR, in *Geography*, a royal burgh of conſiderable antiquity, and the county town of Angus, or Forfarſhire, is ſituated 13 miles N. of Dundee. At what time it was erected into a royal burgh is uncertain; a writ of *novodamus*, however, confirming its privileges as ſuch, with parliamentary ratification, dated 1669, is ſtill in poſſeſſion of the corporation. By virtue of this it is governed by a provoſt, two bailiffs, and nineteen counſellors, elected annually; and conjointly with Perth, Dundee, St. Andrew's, and Cupar-fife, ſends one member to the Britiſh ſenate. The ſtreets are irregular, though they contain many well-built and handſome houſes. The church, an elegant and commodious ſtructure, ſtands nearly in the centre of the town. The ſeſſions-houſe, lately re-built, has a neat front towards the market-place: the lower part is appropriated for priſoners, and the upper conſiſts of a ſpacious ſet of apartments for the tranſaction of municipal buſineſs, public meetings, and amuſements; and here the ſheriff holds his courts. The population of the town is about four thouſand; but it appears by the returns made to government in 1801, the number of houſes in the pariſh amounted to 726, and inhabitants to 5165; the greater part of whom are employed in manufacturing of ſail-cloth, canvas, Oſnaburghs for ſheeting, and other kinds of coarſe linen-cloth, which find a market by the neighbouring ſea-port of Dundee, on the river Tay. In the vicinity of Forfar are ſeveral lakes, or lochs, as they are here termed, *viz.* Reſtenet, Fithie, and Forfar. On the banks of the firſt are the remains of a priory, dependent formerly on the monaſtery of Jedburgh. The ſecond is about a mile in circumference, and the preſent proprietor has lately erected on its margin an elegant boudoir, or ſummer-houe. In the loch of Forfar was formerly an iſland, on which ſtood a caſtle, the reſidence of Malcolm Canmore; at which time it formed alſo a place of religious retirement for queen Margaret; but by the draining occaſioned by digging for peat, this is now united to the land. From this lake iſſues the rivulet, called Dean, which falls into the river Iſla, in its progreſs through Strathmore to the Tay.

FORFARSHIRE. See ANGUS-SHIRE.

FORFEITURE originally ſignifies a tranſgreſſion or offence againſt ſome penal law.

Forfeiture is defined by judge Blackſtone to be a puniſhment annexed by law to ſome illegal act, or negligence in the owner of lands, tenements, or hereditaments, whereby he loſes all his intereſt therein, and they go to the party injured, as a recompence for the wrong which either he alone, or the public together with himſelf, hath ſuſtained.

The word is formed of the baſe Latin *forisfactura*; whence *forfaitura*, and *forfaictura*, and the French *forfait*. *Forisfactura* comes of *forisfacere*, which, according to Iſidore, ſignifies *to hurt*, or *offend*, *facere contra rationem*; and which is not improperly derived of *foris*, *out*, and *facere*, *to do*; q. d. an action out of rule, or contrary to the rules.

But with us, it is now more frequently uſed for the effect of ſuch trangreſſion, or the loſing ſome right, privilege, eſtate, honour, office, or effects, in conſequence thereof, than for the tranſgreſſion itſelf: as forfeiture of eſcheats, forfeiture of goods, &c. A fee becomes vacant by the forfeiture or rebellion of the vaſſal.

Goods forfeited, and goods confiſcated, differ: thoſe which have a known owner, who has committed ſome offence, whereby he loſes his goods, are ſaid to be forfeited: thoſe which an offender diſavows, as not his own, and which are not claimed by any other, are ſaid to be confiſcated; ſtat. 25 Edw. III. Add, that forfeiture, or forfeit, is more general; and confiſcation more particular, being principally uſed for ſuch as forfeit only to the king's exchequer.

FORFEITURE, *full*, *plena forisfactura*, called alſo *plena vita*, is a forfeiture of life and member, and all elſe that a man has.

This obtains in criminal caſes, as where a perſon is attainted of treaſon, felony, &c. There is alſo a forfeiture of lands, &c. in civil caſes. There are various degrees and various means, whereby lands, tenements, and hereditaments, may be forfeited. 1. By crimes and miſdemeanors: of theſe, the principal offences that induce a forfeiture of lands and tenements to the crown, are treaſon, felony, miſpriſion of treaſon, præmunire, drawing a weapon on a judge, or ſtriking any one in the preſence of the king's principal courts of juſtice, and popiſh recuſancy, or non-obſervance of certain laws enacted in reſtraint of papiſts.

Forfeiture in criminal caſes is two-fold: *viz.* of real and perſonal eſtates. 1. As to real eſtates; by attainder in high treaſon a man forfeits to the king all his lands and tenements of inheritance, whether fee-ſimple, or fee-tail, and all his rights of entry to lands and tenements, which he had at the time of the offence committed, or at any time afterwards to be for ever veſted in the crown; and alſo all the profits of all lands and tenements which he had in his own right for life or years, ſo long as ſuch intereſt ſhall ſubſiſt. (Co. Litt. 392. 3 Inſt. 19. 1 Hal. P. C. 240. 2 Hawk. P. C. 448. Stat. 26 Hen. VIII. c. 13). This forfeiture relates backwards to the time of the treaſon committed;

committed; ſo as to avoid all intermediate ſales and incumbrances (3 Inſt. 211.); but not thoſe before the fact: and, therefore, a wife's jointure is not forfeitable for the treaſon of her huſband, becauſe it was ſettled upon her previous to the treaſon committed. But her dower is forfeited by the expreſs proviſion of ſtatute 5 and 6 Edw. VI. c. 11. And yet the huſband ſhall be tenant by the curteſy of the wife's lands, if the wife be attainted of treſon (1 Hal. P. C. 359.): for that is not prohibited by the ſtatute. But, though after attainder, the forfeiture relates back to the time of the treaſon committed, yet it does not take effect unleſs an attainder be had, of which it is one of the fruits; and, therefore, if a traitor dies before judgment pronounced, or is killed in open rebellion, or is hanged by martial law; it works no forfeiture of his lands, for he never was attainted of treaſon (Co. Litt. 13.) But if the chief juſtice of the king's bench (the ſupreme coroner of all England) in perſon upon the view of the body of one killed in open rebellion, records it, and returns the record into his own court, both lands and goods ſhall be forfeited. (4 Rep. 57.)

Forfeiture of lands and tenements to the crown for treaſon is by no means derived from the feodal policy, but was antecedent to the eſtabliſhment of that ſyſtem in this iſland; being tranſmitted from our Saxon anceſtors, (Ll. Aelfr. c. 4. Canut. c. 54.); and forming a part of the ancient Scandinavian conſtitution, (Stiernh. de jure Goth. l. ii. c. 6. l. iii. c. 3.) But in certain treaſons relating to the coin, it is provided by ſome of the modern ſtatutes (5 Eliz. c. 11. 18 Eliz. c. 1.) which conſtitute the offence, that it ſhall work no forfeiture of lands, ſave only for the life of the offender; and by all, that it ſhall not deprive the wife of her dower, (ſtat. 8 and 9 W. III. c. 26. 15 and 16 Geo. II. c. 28.) And in order to aboliſh ſuch hereditary puniſhment entirely, it was enacted by ſtatute 7 Ann. c. 21. that, after the deceaſe of the late pretender, no attainder for treaſon ſhould extend to the diſinheriting of any heir, or to the prejudice of any perſon, other than the traitor himſelf. By this act, the law of forfeiture for high treaſon would by this time have been at an end, if a ſubſequent ſtatute had not intervened to give them a longer duration. In order to explain this part of hiſtory, it ſhould be conſidered, that at the time of the union, the crime of treaſon in Scotland was, by the Scotch laws, in many reſpects different from that of treaſon in England; and particularly in its conſequence of forfeiture of entailed eſtates, which was more peculiarly Engliſh; yet it ſeemed neceſſary, that a crime, ſo nearly affecting government, ſhould, both in its eſſence and conſequences, be put upon the ſame footing in both parts of the united kingdoms. In new-modelling theſe laws, the Scotch nation and the Engliſh houſe of commons ſtruggled hard, partly to maintain, and partly to acquire, a total immunity from forfeiture and corruption of blood; which the houſe of lords as firmly reſiſted. At length a compromiſe was agreed to, which is eſtabliſhed by this ſtatute, *viz.* that the ſame crimes, and no other, ſhould be treaſon in Scotland, that are ſo in England; and that the Engliſh forfeitures and corruption of blood ſhould take place in Scotland, till the death of the then pretender; and then ceaſe through the whole of Great Britain; (Burnet's Hiſt. A. D. 1709): the lords artfully propoſing this temporary clauſe, in hopes, as it is ſaid, that the prudence of ſucceeding parliaments would make it perpetual. (Foſt. 250.) This has partly been done by the ſtatute 17 Geo. II. c. 39, (made in the year preceding the late rebellion,) the operation of theſe indemnifying clauſes being thereby ſtill farther ſuſpended, till the death of the ſons of the pretender.

In petit treaſon, miſpriſion of treaſon, and felony, the offender alſo forfeits his chattel intereſts abſolutely, and the profits of all eſtates of freehold during life; and, after his death, all his lands and tenements in fee-ſimple, (but not thoſe in tail,) to the crown, for a very ſhort period of time; for the king ſhall have them for a year and a day, and may commit therein what waſte he pleaſes; which is called the king's "year, day, and waſte." (2 Inſt. 37.) Formerly the king had only a liberty of committing waſte on the lands of felons, by pulling down their houſes, extirpating their gardens, ploughing their meadows, and cutting down their woods. And a puniſhment of a ſimilar ſpirit appears to have obtained in the oriental countries, from the decrees of Nebuchadnezzar and Cyrus, in the books of Daniel (ch. iii. v. 29.) and Ezra (ch. vi. v. 11.); which, beſides the pain of death inflicted on the delinquents there ſpecified, ordain, "that their houſes ſhall be made a dung-hill." But as this tended greatly to the prejudice of the public, it was agreed, in the reign of Henry I. in this kingdom, that the king ſhould have the profits of the land for one year and a day, in lieu of the deſtruction he was otherwiſe at liberty to commit; (Mirr. c. 4. § 16. Flet. l. i. c. 28.); and therefore Magna Carta provides, (9 Hen. III. c. 22.), that the king ſhall only hold ſuch lands for a year and a day, and then reſtore them to the lord of the fee; without any mention made of waſte. But the ſtatute 17 Edw. II. "de prærogativâ regis," ſeems to ſuppoſe, that the king ſhall have his year, day, and waſte; and not the year and day *inſtead* of waſte; which ſir Edward Coke, (and the author of the "Mirror" before him,) very juſtly look upon as an encroachment, though a very ancient one, of the royal prerogative, (Mirr. c. 5. § 2. 2 Inſt. 37.) This year, day, and waſte, are now uſually compounded for; but otherwiſe they regularly belong to the crown; and, after their expiration, the land would naturally have deſcended to the heir, (as in gavel-kind tenure it ſtill does,) if its feodal quality did not intercept ſuch deſcent, and give it by way of eſcheat to the lord. Theſe forfeitures for felony do alſo ariſe only upon attainder; and therefore a "felo de ſe" forfeits no lands of inheritance or freehold, for he never is attainted as a felon, (3 Inſt. 55.) They likewiſe relate back to the time of the offence committed, as well as forfeitures for treaſon; ſo as to avoid all intermediate charges and conveyances. As a part of the forfeiture of real eſtates, we might here mention the forfeiture of the profits of lands during life; which extends to two other inſtances beſides thoſe already ſpoken of, the ſtriking in Weſtminſter hall, or drawing a weapon upon a judge then ſitting in the king's courts of juſtice, (3 Inſt. 141.) And it ſeems that the ſame forfeiture is incurred by reſcuing a priſoner in or before any of the courts there, committed by the judges. (Cro. Jac. 567.)

2. The forfeiture of "goods and chattels" accrues in every one of the higher kinds of offence; in high treaſon and miſpriſion thereof, petit treaſon, felonies of all ſorts, whether they be clergyable or not, ſelf-murder or felony *de ſe*, petty larciny, ſtanding mute, and the above-mentioned offences of ſtriking, &c. in Weſtminſter hall. In *flight* alſo, on an accuſation of treaſon, felony, or even petit larciny, whether the party be found guilty or acquitted, if the jury find the flight, the party ſhall forfeit his goods and chattels. But the jury very ſeldom find the flight (Staundf. P. C. 183 *b.*) forfeiture being looked upon, ſince the vaſt increaſe of perſonal property of late years,

as

as too large a penalty for an offence, to which a man is prompted by the natural love of liberty.

Between the forfeiture of lands, and that of goods and chattels, there are ſome remarkable differences. 1. Lands are forfeited upon *attainder*, and not before; goods and chattels are forfeited by *conviction*. 2. In outlawries for treaſon or felony, lands are forfeited only by the judgment; but the goods and chattels are forfeited by a man's being firſt put in the *exigent*, without ſtaying till he is *quinto exactus*, or finally outlawed; for the ſecreting himſelf ſo long from juſtice, is conſtrued a flight in law. (3 Inſt. 232.) 3. The forfeiture of lands has relation to the time of the fact committed, ſo as to avoid all ſubſequent ſales and incumbrances; but the forfeiture of goods and chattels has no relation backwards; ſo that thoſe only which a man has at the time of conviction ſhall be forfeited. Therefore a traitor or felon may *bonâ fide* ſell any of his chattels, real or perſonal, for the ſuſtenance of himſelf and family between the fact and conviction (2 Hawk. P. C. 454.); for perſonal property is of ſo fluctuating a nature, that it paſſes through many hands in a ſhort time; and no longer could be ſafe, if he were liable to return the goods which he had fairly bought, provided any of the prior vendors had committed a treaſon or felony. Yet if they be colluſively, and not *bonâ fide*, parted with, merely to defraud the crown, the law (and particularly the ſtatute 13 Eliz. c. 5.) will reach them; for they are all the while truly and ſubſtantially the goods of the offender; and as he, if acquitted, might recover them himſelf, as not parted with for a good conſideration; ſo in caſe he happens to be convicted, the law will recover them for the king.

Lands which a perſon hath in truſt, or goods and chattels in right of another, or to another's uſe, &c. will not be liable to forfeiture. Though leaſes for years, in a man's own, or his wife's right, eſtates in jointenancy, &c. and all ſtatutes, bonds, and debts due thereby, and upon contracts, &c. ſhall be forfeited. (Co. Litt. 42. 151. Staundf. 188.)

3. There is a forfeiture by *alienation*, (which ſee,) contrary to law, which may be in *mortmain* (ſee MORTMAIN); to an alien, not only on account of his incapacity to hold the lands ſo alienated; which occaſions him to be paſſed by in deſcents of land, but likewiſe on account of his preſumption in attempting, by an act of his own, to acquire any real property, (ſee ALIEN); and by particular tenants, when the alienations are greater than the law entitles them to make, and diveſt the remainder or reverſion; in which caſe they become forfeitures to him whoſe right is hereby injured; there is alſo an alienation by *diſclaimer*, which ſee. 4. By non-preſentation to a benefice, when the forfeiture is denominated a *lapſe*, which ſee. 5. By *ſimony*, which ſee. 6. By breach or non-performance of *conditions*, annexed to eſtates, either expreſſed or legally implied. (See CONDITION.) 7. By *waſte*, which ſee. 8. By breach of copyhold cuſtoms. (See COPYHOLD.) 9. By *bankruptcy*, which ſee. There are alſo various other forfeitures, beſides thoſe already recited, that are inflicted, by ſpecial ſtatutes, for particular crimes and miſdemeanors; ſome of which are *mala in ſe*, or offences againſt the divine law, either natural or revealed; but by far the greateſt part are *mala prohibita*, or ſuch as derive their guilt merely from their prohibition by the laws of the land; ſuch as the forfeiture of 20*s.* per month by the ſtat. 5 Eliz. cap. 4. for exerciſing a trade without having ſerved ſeven years apprenticeſhip to it; and the forfeiture of 1*l.* by 9 Ann. cap. 23. for printing an almanack without a ſtamp. Thus alſo artificers, going out of the kingdom and teaching their trade to foreigners, are liable to forfeit their lands, &c. by ſtat. 5 Geo. I. c. 27. (See MANUFACTURES.) In all caſes where a penalty or forfeiture is given by ſtatute, without ſaying to whom it ſhall be, or a limitation for a recompence for the wrong to the party, it belongs to the king. (Stra. 50. 828. 2 Vent. 267.) And ſuch forfeitures ſhall be conſtrued favourably. (Cowp. 585. 8.) Blackſt. Com. vol. ii. p. 267, &c. 420, &c. vol. iv. p. 370, &c. 416. &c.

Goods or lands of one arreſted for felony ſhall not be ſeized before he is convict or attaint of the felony, on pain of forfeiting double value. (Stat. 1 R. III. c. 3.) Goods of a felon, &c. cannot be ſeized before they are forfeited; though they may be inventoried, and a charge made thereof before indictment. (Wood's Inſt. 659.) When goods of a felon are pawned before he is attainted, the king ſhall not have the forfeiture of the goods till the money is paid to him to whom they were pawned. 3 Inſt. 17. 2 Nelſ. Abr. 874. 5.

The true reaſon of any forfeiture, for crimes, ſays judge Blackſtone, is this: that all property is derived from ſociety, being one of thoſe civil rights which are conferred upon individuals, in exchange for that degree of natural freedom, which every man muſt ſacrifice when he enters into ſocial communities; if, therefore, a member of any national community violates the fundamental contract of his aſſociation, by tranſgreſſing the municipal law, he forfeits his right to ſuch privileges as he claims by that contract; and the ſtate may very juſtly reſume that portion of property, or any part of it, which the laws have before aſſigned him. Hence, in every offence of an atrocious kind, the laws of England have exacted a total confiſcation of the moveable or perſonal eſtate; and in many caſes a perpetual, in others only a temporary loſs of the offender's immoveables or landed property; and have veſted them both in the king, who is the perſon ſuppoſed to be offended, being the one viſible magiſtrate in whom the majeſty of the public reſides. Blackſt. Com. vol. i. p. 299.

FORFEITURE *of marriage*, *foriſfactura maritagii*, a writ which formerly lay againſt him, who, holding by knight's ſervice, and being under age, and unmarried, refuſed her whom the lord offered him, without his diſparagement, and married another. F. N. B. 141. Reg. Orig. 163.

FORFEX, in *Surgery*, a pair of ſciſſars wherewith things may be cut.

The word is ſometimes alſo uſed for pincers, nippers, or pliers; and is often confounded with forceps. Blanchard, and after him Quincy, deſcribes a forfex as an inſtrument for drawing teeth.

FORFICULA, in *Entomology*, a genus of the coleoptera order, in the Linnæan ſyſtem, diſtinguiſhed by the following eſſential characters: antennæ ſetaceous; feelers unequal and filiform; wing-caſes about half the length of the abdomen; wings folded up under the wing-caſes; tail armed with forceps. This is the earwig of Engliſh writers.

The forficulæ can ſcarcely be conſidered with propriety as appertaining to the coleopterous tribes of inſects; and later writers ſeem ſo well aſſured of this, that few continue in this reſpect to follow the example of Linnæus. Fabricius, with more conſiſtency, has placed them in his claſs *ulonata*, together with the blattæ, the mantes, phaſmæ, and other analogous families; and hence we may conceive, had Fabricius been himſelf diſpoſed to adopt the ſyſtem propoſed by Linnæus, he would have placed the forficulæ in the hemiptera inſtead of coleoptera order. There are ſtill objections to this, and we cannot avoid approving, in preference to either, the ſuggeſtion of Latreille, that they conſtitute

conſtitute an intermediate order between the coleoptera and hemiptera. La Marck had previouſly conſtituted a new order for the reception of the forficulæ, blattæ, and other inſects of the ſame natural tribe, to which he gave the name orthoptera; yet he does not place it between the two orders before mentioned: it ſtands in his arrangement between the coleoptera and neuroptera.

The two ſexes of the forficulæ differ a little in general form, and alſo in the ſhape and bulk of the abdomen, as well as the forceps at the extremity of the abdomen. The female is diſtinguiſhed by the ſuperior ſize of the abdomen. The eggs are large, white, and gloſſy; and the larvæ, when hatched, conſiderable in proportion to the magnitude of the egg from whence they are excluded. Few of the inſect tribe evince more attention to their young than the females of the forficulæ. In the firſt inſtance, they are particularly careful to depoſit their eggs in places of ſecurity, and are often ſeen ſitting on them for hours together; and they are alſo known to regard the infant brood with tenderneſs, the young remaining in ſociety with the parent ſome time after being produced from the egg. The forficulæ live in moiſt places, among plants, or under rotten wood and ſtones; and are injurious in particular to the kitchen and flower gardens, as the ravages of the more frequent ſpecies, the common earwig, ſufficiently atteſt.

Species.

Herculeana. Forceps elongated, in the middle beſet with a ſingle tooth, black; legs rufous. Fabr. Suppl.

The largeſt of this genus. The head is black; antennæ ferruginous; thorax flat, ſmooth, and black; wing caſes ſhort, deep black, and without ſpots; body deep black; forceps nearly the length of the body. This ſpecies inhabits the iſland of St. Helena.

Ruficollis. Black; thorax and wing-caſes in the diſc, with the legs ferruginous. Fabr.

A ſpecies of large ſize, found in Africa. The head is black; antennæ teſtaceous, and conſiſting of eleven joints; abdomen black; forceps curved, black, and armed with a ſingle tooth at the baſe.

Gigantea. Pale, variegated above with black; tail bidentated; forceps advanced and armed with a ſingle tooth. Fabr. *Forficula bilineata*, Herbſt. *Gigantic earwig*, Donov. Brit. Inſ.

Inhabits the ſouth of Europe, and is rare in Britain; its magnitude double that of the common kind.

Auricularia. Wing-caſes white at the tip; forceps curved, and denticulated at the baſe; antennæ of fourteen joints. Linn. Fn. Suec., &c. *Forficula major*, Degeer. *Scarabæus ſubrufus, cauda furcata*, Liſter. *Vermis auricularius*, Friſch. *Earwig*, Donov. Brit. Inſ.

Very common in wet places throughout Europe; infeſts fruit-trees and flowers, and is ſaid to creep into the ears of ſuch as ſleep in the open air; whence the name of earwig, or ear-piercer.

Annulata. Black; extreme joint but one of the antennæ, with the legs white. Fabr.

A ſmall ſpecies. The antennæ contain thirteen joints, and are black, except the firſt joint, and the laſt joint but one; legs pale; thighs with a brown annulation. It inhabits South American iſlands.

Bipunctata. Black; hind part of the head, with the legs rufous; wing-caſes with a white ſpot. Fabr.

Native of Italy. The antennæ contain only eleven joints.

Biguttata. Black; wing-caſes with a yellow ſpot; forceps incurved, denticulated in the middle. Fabr.

A ſpecies of moderate ſize, found in Hungary.

Fulvipes. Black; mouth, ſides of the abdomen, and legs white. Fabr.

Large; the antennæ pale, and containing eleven joints; the forceps large, and denticulated within. This ſpecies inhabits Cayenne.

Albipes. Black; thorax behind; baſe of the wing-caſes, wings, and legs white. Fabr.

About the middle ſize, and inhabits the South American iſlands.

Minor. Wing-caſes teſtaceous, and immaculate; antennæ of ten joints. Linn.

A native of Europe, and is eſteemed a rare ſpecies. The antennæ are whitiſh at the tip.

Pygmæa. Black; thorax ſquare, with pale margin; antennæ and legs teſtaceous. Fabr.

Infeſts plants in Guinea. A ſmall ſpecies.

Flexuosa. Forceps flexuous; wing-caſes with yellow dots. Fabr.

Native of Cayenne. The body is brown, and the forceps ferruginous at the baſe.

Dentata. Antennæ of ten joints; body brown; edges of the thorax and legs pale; forceps toothed at the baſe. Fabr.

Inhabits Madeira. The abdomen is brown, extremity of the abdomen armed with four teeth; forceps large, curved, and black.

Erythrocephala. Black; head and tail ferruginous; ſpots on the abdomen, and legs yellowiſh. Fabr.

A ſpecies of moderate ſize, and inhabits South American iſlands.

Elongata. Duſky; margin of the thorax, wing-caſes, and legs pale; forceps with a ſingle tooth at the baſe. Fabr.

Inhabits ſame iſlands as the laſt, and reſembles it in ſize.

Morio. Deep black; antennæ with a white band. Fabr.

A large ſpecies, found in Otaheite. The antennæ conſiſt of eighteen joints of a black colour, except the firſt, fourth, and fifteenth articulations, which are white; the wings are hyaline, with the tip black; and the legs ferruginous at the end.

Parallella. Black; edges of the thorax, wing-caſes, and legs pale; forceps ſtraight and unarmed. Fabr.

Native of Madeira.

Flavipennis. Black; wing-caſes yellowiſh, with a black future. Fabr.

About the middle ſize, and inhabits Senegal. The head is obſcure rufous, with a black frontal ſpot; thorax margined and blackiſh; body black; legs yellow.

Pallipes. Forceps long, with a ſingle tooth; body black; legs white. Fabr.

A large ſpecies. The antennæ pale; wings white, with a brown line at the tip; forceps nearly as long as the abdomen, ferruginous, and tipped with black.

Livida. Livid; very minute; forceps very minutely denticulated. Linn.

Native of Europe.

Forficula *Marina*, the *ſea earwig*, a name given by authors to an inſect frequently found about the ſea-ſhores, and having ſome ſort of external reſemblance to the common earwig. It is of the ſize of the common earwig, and is of a mixed colour, of a deep black and a ſilvery white. The ſhoulders are ſomewhat gibboſe, the eyes ſtanding cloſe to one another on the ſummit of the head; the antennæ are long and very ſlender. It has eight pair of legs on the anterior part of the body, and eight pair more at the hin-

der part, and there are three or four briſtles at the tail. It moves about very ſwiftly, and lives on rocks and among ſtones.

FORGAVEL, Forgabulum, in *Antiquity*, a ſmall reſerved rent in money, or quit-rents.

FORGE, properly ſpeaking, is any kind of furnace, the heat of which is afforded by the action of bellows. The term, however, is now more particularly applied to the common ſmith's forge, and to the forge uſed for the manufacture of bar iron. For a deſcription of the latter, ſee Iron.

A peculiar ſpecies of forge is alſo uſed for the manufacture of ſhear ſteel; for an account of which, ſee Steel. The common ſmith's forge requires bellows of different kinds and ſizes, agreeable to the nature of the work.

The double bellows are chiefly uſed for the working of iron, and ſingle ones for ſteel. The double bellows are apt to blow ſome time after the workman takes out one of his irons; and as in working ſteel, the heat is leſs than that employed for iron, the rod of ſteel, if left in the fire, would be often liable to be burned, as the workmen term it. The ſingle bellows are, therefore, better adapted for this work, becauſe the blaſt does not continue after the workman leaves the bellows.

The fire-place is generally a flat hearth, nearly on a level with the blaſt, on which the fuel is placed, which moſtly conſiſts of the coaks of pit-coal. In ſmithery, however, and more particularly for the working of ſteel, the coal ſhould be carefully ſelected, as free from pyrites as poſſible, as the ſulphur of that ſubſtance is found to be very injurious to the metal. In all caſes where welding is required, the ſulphur totally prevents the adheſion. If pyrites ſhould by accident get into the fire, the beſt means to get rid of it is to throw a quantity of iron-filings into the fire, which immediately takes up the ſulphur.

After the coaks have been uſed for ſome time, the pieces become exceedingly ſmall, and are ſo light as to be blown away by the bellows, ſeparating the fuel from the iron. This inconvenience is removed by taking away theſe ſmall particles from time to time. It, however, may be much eaſier removed by a contrivance which is not in general uſe. This is effected by making the bed of the hearth a grate, about four inches below the level of the blaſt. The ſmall duſt, paſſing through the grate upon an inclined plane, is carried away, leaving nothing on the hearth but the proper fuel.

In moſt of theſe forges, particularly where great heat is required, the nozel of the bellows is not preſented to the fire. A thick iron tube is placed between the bellows and the fire, called the tuiron. It is funnel-ſhaped at the end next the bellows, for the reception of the nozel of the bellows; and has a cylindric hole, from about the middle to the oppoſite end, a little leſs than the aperture at the nozel of the bellows.

Before means were contrived of preventing the tuiron from being raiſed above a certain temperature, it was very ſpeedily worn out by the heat and the oxydation of the iron. This evil has been removed by the invention of what is now called the water-tuiron. It conſiſts of ſomething like the common tuiron, having a crooked tube paſſing through the body of it. One end of the tube, at ſome diſtance from the tuiron, is inſerted into the bottom of a tub, filled with water; the other end coming from the tuiron paſſes over the top of the tub: ſo that the cold water has conſtant acceſs to the body of the tuiron, which the heat of the fire raiſes into vapour. This vapour paſſes up the other tube, which condenſing, is diſcharged into the tub. By this means, it is evident that the tuiron can never much exceed the heat of boiling water. This contrivance prevents a much greater evil than the deſtruction of the tuiron. The oxyd of iron, which is conſtantly formed from the heated iron, combining with the earthy matter of the coal, forms a very fuſible ſcoria, which, if the tuiron were not kept cool, would be apt to adhere to it, and ſtop up its aperture. This ſcoria may be eaſily diſcharged through the grate of the hearth, which would at any rate be an interruption to the blaſt.

The large quantity of oxygen conſtantly blown into the fire, upon the iron, at ſo high a temperature, cauſes a very rapid oxydation of the metal. This oxyd has ſome tendency to vitrification, and conſequently to prevent the iron, in ſome meaſure, from the future attacks of oxygen. Since, however, ſilex forms a very fuſible vitreous compound with the oxyd of iron, the ſmith is in the habit of uſing the powder of any ſtone of a ſandy nature. When the iron becomes nearly of a welding heat, he takes it out to immerſe it in the powdered ſand. A thin fluid ſubſtance is immediately ſeen to flow over the heated ſurface, which defends the metal from the oxygen. In the welding of one piece of iron to another, the uſe of ſand is highly important, and more particularly in welding ſteel to iron. When the two ſurfaces are brought together, the oxyd of iron, with the flint, is removed by reaſon of its great fluidity. If, however, the oxyd were not rendered thus fluid, it would remain and prevent the adheſion of the ſurfaces.

Lead is found to be very injurious to the ſmith's fire; it combines with ſomething on the ſurface of the iron, which makes it unfit for welding. Its preſence is eaſily known, as the iron affected with it makes a brown mark upon the anvil. The ſtrongeſt heat of a forge is at about two inches from, and a little above the aperture of the tuiron.

A forge is alſo uſed by braziers, copper-ſmiths, and in the plated manufactories. This conſiſts of a hearth like the ſmith's forge, and a pair of bellows. The fuel is moſtly coak, but ſometimes for particular purpoſes charcoal. It is uſed for annealing their metal previous to working it, and alſo for ſoldering.

The forge fire is not well calculated for the fuſion of metals, ſince the ſide of the crucible next the blaſt is liable to be cooled, which generally cauſes it to break. The portable blaſt furnace is however better adapted than the common forge, as the air is introduced at bottom, like the common air furnace. See Furnace.

Forging conſiſts in changing the form of ſuch malleable metals as may have been heated for that purpoſe in the fire of the forge, by means of the hammer and other inſtruments uſed in ſmithery.

Several of theſe proceſſes are carried on by machinery worked by water or ſteam. In the manufacture of bar iron, very large maſſes of this metal, called blooms, are drawn into bars by an immenſe hammer, worked by a water wheel, or the ſteam-engine. See Iron.

The forging of ſcythes is alſo performed by ſimilar power, which by the workmen is called ſkelping. See Scythe.

Forging, however, more properly belongs to the forming of various utenſils from iron, and other malleable metals.

The anvil, on which the metal is laid, conſiſts of a large maſs of wrought iron, faced with hardened ſteel, and ground ſmooth on the ſurface. The hammers are of the ſame materials, and are of different ſizes, agreeable to the nature of the work. If the work is heavy, beſides the perſon who holds the ſubſtance to be hammered, a ſecond, and ſometimes a third and fourth perſon ſtrike in turns at the heated body. If the body requires to be made round, in-

ſtruments called *ſwages* are employed. They conſiſt of two maſſes of iron faced with ſteel, and hardened, one lying upon the anvil, or faſtened into a groove in the anvil, and the other held in the hand, by means of a piece of hazel ſtick twiſted round it. In the faces of each of theſe ſwages a proper ſized groove is made, which, for ſwaging round bodies, is a ſegment of a cylinder. The body to be ſwaged being laid upon the lower one, the upper ſwage is placed upon it, on which a perſon ſtrikes with a large hammer, while the body to be made cylindrical is turned round. A variety of other inſtruments are uſed according to the nature of the work to be done. Iron admits of being forged with greater facility than ſteel, as it is much ſofter, and can be heated to a much greater heat, which ſtill makes it ſofter. Indeed iron is generally heated to a welding heat, in order that its parts, which are frequently looſe and unconnected, may be made ſound.

Copper may be forged into any ſhape, but will not bear more than a red heat, and of courſe requires to be heated often. The bottoms of large boilers are frequently made by a large forge hammer worked by machinery. The bolts of copper uſed for ſhips, and other purpoſes, are moſtly made by the hammer. Silver, gold, and platina will alſo admit of forging into any form. Of the former metal, ſilver knives are made very neatly by the hammer. The heat at which it is worked ſhould be barely that of ignition.

It is remarkable that alloys of the malleable metals, although very malleable when cold, will not bear the hammer when heated.

Forge is alſo uſed for a large furnace, wherein iron ore, taken out of the mine, is melted down.

But this is not ſo properly called a forge as a *furnace*; which ſee.

Forge is more properly uſed for another kind of furnace wherein the iron ore, melted down and ſeparated in a former furnace, and there caſt into ſows and pigs, is heated; and fuſed over again, and beaten afterwards with large hammers, and thus rendered more ſoft, pure, ductile, and fit for uſe.

Of theſe forges there are two kinds, which the iron ſucceſſively paſſes through, before it comes to the ſmith.

The firſt is called the *finery*, where the pigs are worked into groſs iron, and prepared for the ſecond, which is called the *chafery*, where it is farther wrought into bars fit for uſe.

Forge-*mills*. See Mill.

Forge-*volant*, or *Flying-forge*, means ſuch an arrangement of the ſeveral implements and materials, neceſſary for the eſtabliſhment of a ſmith's forge, within a cart or waggon, as may qualify it to accompany an army during a campaign, with the ſame facility as the ſeveral carriages appertaining to the train of artillery.

It will be immediately underſtood, that much contrivance, and great attention to regularity, are needful to accompliſh and preſerve ſo eſſential a purpoſe; the more ſo, as the whole weight of the forge and its ſupplies of fuel, &c., ſhould not exceed half a ton when conveyed in a cart; nor a whole ton when carried in a waggon. The beſt mode is to place the anvils and their blocks in ſuch a poſition as to balance well, but to be eaſily lifted in and out. For minor purpoſes two or three ſmall anvils may be attached temporarily to the hinder tranſom of the cart-body. There ſhould be a water trough, a furnace, and a pair of bellows, all within a frame of iron plate, properly rivetted and cloſed with hard ſolder, ſo as to be firm, and to prevent latent ſparks from ſetting fire to the machine, or to its contents. The tail-board ſhould let down to a level with the bottom of the cart, and be ſuſpended in that direction by ſtrong ſegments of iron; ſo as to be well fixed, and to reſiſt preſſure either upwards or downwards; the ſides around the furnace and bellows ought to be divided into compartments for the reception of fuel, (generally charcoal,) ſufficient for immediate ſervice, and for the aſſortment of nails, ſcrews, clouts, ſwivels, pins, nuts, horſe ſhoes and nails, bridle chains, buckles, &c., in ſmall quantities, ſo that any thing wanting immediate repair may be fitted without the ſmalleſt delay.

Every forge ſhould carry implements ſufficient to employ forty men; of whom two ſhould be fire-men, ſix ſledge-men, ten light hammer-men, two ſcrew and nut-men, and the reſidue, file-men, or workers on cold metal. If the apparatus be carried in a waggon that can contain two double forges, or furnaces, double the number of men may be employed; ſmall anvils, in either caſe, as alſo vices, being made to ſcrew, or to hook, on to the ends of the ſeveral projecting tranſoms, and even to the naves of the wheels, of which the iron tires become uſeful for light hammer work. The total weight of a forge-waggon, excluſive of its contents, ſhould never exceed 15 cwt. In our arſenals they are made even lighter, their average being 13 cwt. 2 qrs. 14 lbs. Being rated with what are called "Park carriages," it is neceſſary they ſhould conform as nearly as may be practicable with others of their claſs, and be drawn by the number of horſes, &c. uſually employed for light machines.

Forge *for red-hot balls*, is a place where the balls are made red-hot before they are fired off: it is conſtructed about five or ſix feet below the ſurface of the ground, of ſtrong brick-work, and an iron grate, upon which the balls are laid with a large fire under them.

FORGER *of falſe deeds*, ſignifies either him that fraudulently makes and publiſhes falſe writings, to the prejudice of any man's right, or elſe the writ that lies againſt him who commits this offence.

Fitz. Nat. Br. fol. 69. B. ſays, that a writ of deceit lies againſt him who commits this offence; and the penalty of it is declared in the ſtat. 5 Eliz. cap. 14.

FORGERY, in *Law*, may be defined (at common law) the fraudulent making or alteration of a writing to the prejudice of another man's right; and it is an offence which was puniſhed by the civil law with deportation or baniſhment, and ſometimes with death: and by the common law the offender may ſuffer fine, impriſonment, and pillory. Alſo, by a variety of ſtatutes, a more ſevere puniſhment is inflicted on the offender in many particular caſes, which are ſo multiplied of late as almoſt to become general. The principal inſtances are as follow:

By ſtatute 5 Eliz. c. 14. to forge or make, or knowingly to publiſh or give in evidence, any forged deed, court roll, or will, with intent to affect the right of real property, either freehold or copyhold, is puniſhed by a forfeiture to the party grieved of double coſts and damages; by ſtanding in the pillory, and having both his ears cut off, and his noſtrils ſlit, and ſeared; by forfeiture to the crown of his lands, and by perpetual impriſonment. For any forgery relating to a term of years, or annuity, bond, obligation, acquittal, releaſe, or diſcharge of any debt or demand of any perſonal chattels, the ſame forfeiture is given to the party grieved; and on the offender is inflicted the pillory, loſs of one of his ears, and a year's impriſonment; the ſecond offence in both caſes being felony without benefit of clergy.

Beſides this general act, a multitude of others, ſince the revolution (when paper credit was firſt eſtabliſhed) have inflicted

flicted capital punishment on the forging, altering, or uttering as true, when forged, of any bank bills or notes, or other securities (stat. 8 and 9 W. III. c. 20. § 36. 11 Geo. I. c. 9. 12 Geo. I. c. 32. 25 Geo. II. c. 13. 13 Geo. III. c. 79.); of bills of credit issued from the exchequer, according to the several acts for issuing them; of South-sea bonds, &c. (stat 9 Ann. c. 21. 6 Geo. I. c. 4. and 11. 12 Geo. I. c. 32.); of lottery tickets or orders, by the several lottery acts; of army or navy debentures (stat. 5 Geo. I. c. 14. 9 Geo. I. c. 5.); of East India bonds (stat. 12 Geo. I. c. 32.); of writings under seal of the London, or Royal Exchange assurance (stat. 6 Geo. I. c. 18.); of the hand of the receiver of the pre-fines (32 Geo. II. c. 14.); or of the accountant-general and certain other officers of the court of chancery (12 Geo. I. c. 32); of a letter of attorney, or other power to receive or transfer stock or annuities; and on the personating a proprietor thereof, to receive or transfer such annuities, stock, or dividends (8 Geo. I. c. 22. 9 Geo. I. c. 12. 31 Geo. II. c. 22. § 77.); also on the personating, or procuring to be personated, any seaman, or other person, entitled to wages or other naval emoluments, or any of his personal representatives; and the taking, or procuring to be taken, any false oath in order to obtain a probate, or letters of administration, in order to receive such payments; and the forging, or procuring to be forged, and likewise the uttering or publishing, as true, of any counterfeited seaman's will or power (stat. 31 Geo. II. c. 10. 9 Geo. III. c. 30.); to which may be added, though not strictly reducible to this head, the counterfeiting of Mediterranean passes, under the hands of the lords of the admiralty, to protect one from the piratical states of Barbary (4 Geo. II. c. 18.); the forging or imitating of any stamps to defraud the public revenue (according to the several stamp acts); and the forging of any marriage register or licence (26 Geo. II. c. 33.); all which are by distinct acts of parliament made felonies without benefit of clergy. By statutes 13 Geo. III. c. 52. and 59. forging or counterfeiting any stamp or mark to denote the standard of gold and silver plate, and certain other offences of the like tendency, are punished with transportation for fourteen years. By statute 12 Geo. III. c. 48. certain frauds on the stamp duties, therein described, principally by using the stamps more than once, are made single felony, and liable to transportation for seven years; and the same punishment is inflicted by stat. 13 Geo. III. c. 38. on such as counterfeit the common seal of the corporation for manufacturing plate glass (thereby erected), or knowingly demand money of the company by virtue of any writing under such counterfeit seal.

There are also certain other general laws with regard to forgery; of which the first is 2 Geo. II. c. 25. whereby the first offence in forging or procuring to be forged, acting or assisting therein, or uttering or publishing as true, any forged deed, will, bond, writing obligatory, bill of exchange, promissory note, indorsement or assignment thereof, or any acquittance or receipt for money or goods, with intent to defraud any person (or corporation) is made felony without benefit of clergy. And by statutes 7 Geo. II. c. 22. and 18 Geo. III. c. 18. it is equally penal to forge or cause to be forged, or utter as true, a counterfeit acceptance of a bill of exchange, or the number or principal sum of any accountable receipt for any note, bill, or any other security for money; or any warrant or order for the payment of money, or delivery of goods. There is now hardly a case to be conceived, wherein forgery, that tends to defraud, whether in the name of a real or fictitious person, is not made a capital crime. (Foft. 116, &c.) Blackft. Com. B. iv.

FORGES, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton in the district of Neufchatel, famous for its mineral waters of a ferruginous quality; near the source of the Epte, nine leagues N.E. of Rouen, and 25 N.N.W. of Paris. The place contains 1,201, and the canton 11,757 inhabitants, on a territory of 242½ kiliometres, in 31 communes.

FORGESIA, in *Botany*, so named by Commerson the French botanist and traveller, in honour of his friend and patron, M. Desforges, governor of the isle de Bourbon, at the time when he investigated the vegetable productions of that country with so much success. Juss. 164. (Defforgia; Lamarck. Illustr. t. 125.) Class and order, *Pentandria Digynia*. Nat. Ord. *Campanulaceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, in five deep, ovate, acute, equal, spreading, permanent segments. *Cor.* of five equal, oblong, upright petals, twice the length of the calyx, cohering by their broad bases, reflexed at the tip, clothed with short hairs on their inner side, especially upwards. *Stam.* Filaments five, equal, the length of the corolla, cylindrical, firm, erect, roughish; anthers fixed, incumbent, heart-shaped, two-lobed. *Pist.* Germen inferior, turbinate, convex at the top, of two cells; styles two, cohering in a columnar form, erect, the length of the stamens, permanent, roughish; stigmas divaricated, globose, undivided. *Peric.* Capsule encircled with the calyx, opening at the top by two valves, crowned with the styles, of two cells. *Seeds* numerous, small.

Ess. Ch. Petals five, rough on their inside. Capsule inferior, of two cells and two valves, crowned by the styles.

Obs. Commerson observed that the styles are sometimes, though very rarely, three, the cells and valves of the fruit agreeing with them in number. Jussieu suggests that this genus is akin to his order of *Onagræ*, as well as to *Heucheræ* amongst his *Saxifragæ*. We follow him in referring it to the *Campanulaceæ* for the present, though it ill accords with the characters of that order, having two styles. It has indeed somewhat of the habit of *Campanula aureæ*, but little else in common. To *Escallonia*, one of Jussieu's *Onagræ*, it has a very great affinity in every part, except the two styles, which last mark seems of the less moment, as their germens accord in having two cells. Wherever *Escallonia* is to remain, *Forgesia* must certainly, as we find Lamarck has observed, go along with it. In the artificial system, the latter should follow *Heuchera*; in the natural, or rather *conjectural* one (if we may be allowed the term), it is related to *Ribes*, *Heuchera*, *Escallonia*, *Fœtidia*, *Philadelphus*; scarcely, if at all, to *Campanula*.

1. F. *borbonica*. (Defforgia borbonica; Lamarck. Illustr. v. 2. 71.) Native of the isle de Bourbon. A *tree*, smooth in every part, except the flower. *Leaves* numerous, scattered, three or four inches long, obovate, acute, serrated, with one rib and numerous transverse veins; paler beneath; on stalks an inch long. *Panicles* about the ends of the branches, axillary and terminal, spreading, with small, oblong, scattered bracteas. *Flowers* the size of *Campanula aurea*; of their colour we have no information. The whole plant dries of a dull brown. The young shoots are resinous, somewhat astringent, scarcely aromatic.—In this case we tolerate a specific name derived from that of a country, though against sound principle, for the sake of the connection between that country and the person to whom the genus is dedicated. S.

FORGING, in the *Mechanic Arts*, the act of beating or hammering iron on an anvil, after having first made it red-hot in the forge, in order to extend it into various forms, and fashion it into works.

Iron is hammered and forged two ways; either by the force of the hand, in which there are uſually ſeveral perſons employed, one of them turning the iron, and hammering likewiſe, and the reſt only hammering.

Or, it is done by the force of a water-mill, which raiſes and works ſeveral huge hammers, beyond the force of man, under the ſtrokes whereof the workmen preſent large lumps or pieces of iron, which are ſuſtained, at one end, by the anvils, and, at the other, by iron chains faſtened to the cieling of the forge.

This laſt way of forging is only uſed in the largeſt works, as anchors for ſhips, &c. which uſually weigh ſeveral thouſand pounds. For the lighter works, a ſingle man ſuffices to hold, heat, and turn, with one hand, while he ſtrikes with the other. Each purpoſe for which the work is deſigned requires its proper heat. If it be too cold, it will not feel the weight of the hammer, as the ſmiths call it, *i. e.* it will not ſtretch or give way; and if it be too hot, it will red-ſear, *i. e.* it will break or crackle under the hammer.

The ſeveral heats the ſmiths give to their irons, are, 1. A blood-red heat. 2. A white-flame heat. 3. A ſparkling or welding heat. See Forge.

Forging *Over*, in *Sea Language*, denotes the art of forcing a ſhip violently over a ſhoal, by the effort of a great quantity of ſail.

FORHAD, in *Geography*, a town of Perſia, in Choraſan; 40 miles E.S.E. of Niſabour.

FORI, a town of Japan, in the iſland of Niphon; 10 miles E. of Scoda.

FORIANI, a town of the department of Golo, in the iſland of Corſica; four miles S. of Baſtia.

FORK-Tail, among the *Fiſhermen of England*, a name given to the ſalmon, while in the fourth year's growth, and not yet come to what they call a ſalmon.

Forked *Head*, in *Geography*, a cape on the S. coaſt of the iſland of Cape Breton. N. lat. 45° 42′. W. long. 60° 4′.

Forked *Deer river*, a river of America, which runs into the Miſſiſſippi. N. lat. 35° 22′. W. long. 90° 4′. It is about 76 yards wide, 7 miles from its mouth.

Forked *Beard, great*, in *Ichthyology*, a name given on the coaſt of Cornwall to the *blennius phycis* of Linnæus.

Forked *Heads*, among *Hunters*, thoſe horns of deer which bear two croches on the top, or which have their croches doubled.

FORKEN, in *Geography*, a town of Pruſſia, in the province of Samland; 4 miles N.E. of Fiſchauſen.

FORKS, a townſhip of America, in Northampton county, Pennſylvania, having 884 inhabitants.

FORLANA, Ital. in *Muſic*, the air of a dance of the ſame name, very common at Venice, eſpecially among the Gondolieri. Its time is $\frac{6}{8}$ played with ſpirit; and the dance is very gay. It is called *Forlana* from being invented and common in Friuli, where the inhabitants are called *Forlani*.

FORLAZZO, in *Geography*, a town of Naples, in the province of Bari; 11 miles S.E. of Teramo.

FORLET-Land, a term applied to ſuch land, in the biſhopric of Hereford, as was formerly granted or leaſed out, "dum epiſcopus in epiſcopam ſteteris," in order that the ſucceſſor might have it for his preſent income. This cuſtom is now however in diſuſe, and ſuch lands let or granted, as in other caſes, by leaſe, but they ſtill retain the name.

FORLI, in *Geography*, a town of Italy, in the department of the Amona, the ſee of a biſhop, ſuffragan of Ravenna; containing ten churches and many convents. It was anciently called "Forum Julii." Having been for ſeveral ages under the dominion of the Romans, Forli recovered its liberty under the exarchs, and became powerful enough to gain conſiderable advantages in a war with its neighbours. In 1248 it was taken by the Bologneſe, but found means to emancipate itſelf from their yoke in the year 1296. After a civil war Forli was ſo reduced as to be obliged to ſubmit to the popes. The town is ſurrounded with ſtrong walls and ſolid towers; the ditches are large, and defended with low works; 33 miles S.E. of Ravenna. N. lat. 44° 13′. E. long. 12° 1′.

FORLIMPOPOLI, a town of Italy, in the department of the Amona; formerly called "Forum Populi," and one of the "fora" on the Via Emilia, where the Roman magiſtrates kept their courts. In the year 700 it was ruined by the Lombards, but afterwards rebuilt by the people of Forli. Pope Gregory XI. who reſided at Avignon, having been offended by its inhabitants, it was razed by order of cardinal d'Avila, his legate-general in Italy. Such was the furious reſentment of this prelate, that in the year 1370 he cauſed it to be ſown with ſalt, and a harrow to paſs over its ruins; the pope alſo transferred the epiſcopal ſee to Bertinero, about $1\frac{1}{2}$ mile diſtant from it. About twenty years after this deſolation Ordeloffi, prince of Forli, re-eſtabliſhed the town and fortified it with a good citadel. But being afterwards ſubjected to the dominion of the popes, it ſunk into a ſtate of irrecoverable deſolation.

FORLORN Hope, a deſignation applied, in the *Military Profeſſion*, to that party which is to take the lead on any duty ſuppoſed to be ſo pregnant with danger as to leave but little hope of ſurviving the enterpriſe. It, however, generally happens, that the forlorn-hope ſuffer far leſs than circumſtances ſhould warrant us to expect: many inſtances have occurred in which they have ſuſtained but little loſs, and an examination of the ſeveral details of caſualties after a breach has been ſtormed, a wall ſcaled, or a deſperate attack made on ſome entrenchment, will be found to throw the ſevereſt part of the carnage upon thoſe troops which follow immediately after the forlorn-hope.

This may appear curious, and contrary to reaſon, but examination of the events ordinarily attendant on ſuch arduous duties will ſolve the problem. In advancing towards a breach, &c. it is uſual to keep up a heavy fire, eſpecially of grape and caſe-ſhot, upon thoſe parts towards which the detachment is proceeding; whereby there uſually appears but little oppoſition in that direction; the forlorn-hope thus advance with at leaſt as much ſafety as their immediate ſupporters, and when they are on the creſt of the breach often preſent an equal front with the defenders, againſt whom they contend nearly on equal terms. But as this conteſt ſometimes laſts for a long time, thoſe who may be detained at the foot of the breach, muſt remain expoſed to whatever fire the garriſon may be able to direct towards that quarter; for which purpoſe every exertion, though temporary only, is ever made. Hence every gun that can be brought to bear, even though openly expoſed to the fire of the beſiegers' batteries, or even to their muſketry, will open upon the foot of the breach, which is ever the ſcite of dreadful havock.

Few ſtorming-parties are exempt from volunteers: it is, indeed, in ſuch "hair-breadth eſcapes in the deadly breach" that the crown of military glory is to be found; conſequently, the forlorn-hope is ſeldom taken in the ordinary routine of duty, but is completed by the aſſociation of men who aim at celebrity, and conſequently at promotion;

and who ſtake their whole *hope* upon what is generally conſidered a moſt *forlorn* ſpeculation.

The party whoſe claim to the deſignation is genuine, rarely exceeds twenty or thirty firelocks, uſually commanded by a ſubaltern, or at the utmoſt by a captain. The reſidue of the volunteers, of all claſſes, are formed into what is called the "ſtorming-party," to which any neceſſary augmentation is ſupplied from choice corps, and eſpecially by the grenadiers of the army; it being a poſt of honour.

FORM, Forma, in *Phyſics*, denotes the manner of being peculiar to each body; or that which conſtitutes it ſuch a particular body, and diſtinguiſhes it from every other. Mr. Harris uſes the term form likewiſe in another ſenſe, as an efficient animating principle; to which he ſuppoſes Ovid to refer in the firſt lines of his Metamorphoſis.

"In nova fert animus mutatas dicere formas
Corpora——"

Theſe animating forms are of themſelves no objects either of the ear, or of the eye; but their nature or character is underſtood in this, that were they never to exert their proper energies on their proper ſubjects, the marble on which the ſculptor exerciſes his art would remain for ever ſhapeleſs, and the harp from which the harper calls forth ſounds would remain for ever ſilent.

Thus, alſo, the animating form of a natural body is neither its organization, nor its figure, nor any other of thoſe inferior forms, which make up the ſyſtem of its viſible qualities; but it is the power, which is yet able to produce, preſerve, and employ theſe. It is the power, which firſt moves, and then conducts that latent proceſs, by which the acorn becomes an oak, and the embryo becomes a man; by which digeſtion is performed in plants and animals, and, which departing, the body ceaſes to live, and its members putrify; and by which every being produces another like itſelf, and every ſpe ies is continued. In animals, it is that higher faculty, which, by employing the organs of ſenſe peculiar to them as animals, diſtinguiſhes them as ſenſitive beings from vegetables; and it is alſo that more noble faculty, which by its own divine vigour, unaſſiſted perhaps with organs, makes and denominates him a being intellective and rational. So that Mr. Harris reckons two ſorts of forms, thoſe which are paſſive elements, and thoſe which are efficient cauſes. And all of them agree in this, that they give to every being its peculiar and diſtinctive character; and on the whole he concludes, that form appears in part to be an element, and in part an efficient cauſe, *i. e.* a cauſe which aſſociates the conſtituent elements of natural ſubſtance, and which employs them, when aſſociated, according to their various and peculiar characters. Harris's Phil. Arrangements, chap. vi.

The philoſophers generally allow two principles of bodies: matter, as the common baſis, or ſubſtratum of all; and form, as that which ſpecifies and diſtinguiſhes each; and which, added to a quantity of common matter, determines or denominates it this, or that; wood, or fire, or aſhes, &c.

Subſtantial forms ſeem to have been firſt broached by the followers of Ariſtotle, who thought matter, under different modes or modifications, not ſufficient to conſtitute different bodies; but that ſomething ſubſtantial was neceſſary to ſet them at a greater diſtance: and thus introduced ſubſtantial forms, on the footing of ſouls, which ſpecify and diſtinguiſh animals.

The conſiderations which the Peripatetics principally inſiſt on, in confirmation of this doctrine, are, 1. That, without ſubſtantial forms, all natural things would be of the ſame ſpecies, nature, and eſſence; which is ſuppoſed to be an abſurdity.

2. That every thing has its peculiar power, motion, and operation: as the magnet, *e. gr.* has that of attracting iron; but that this power does not flow from the matter of the body, which is only paſſive; nor from the accidents: and therefore that it muſt ariſe from a ſubſtantial form.

3. That without ſubſtantial forms, there would be no generation: for a production of accidents is only an alteration.

4. That without ſuch form, the nature of a man and of a lion would not differ.

What contributed much to their error, was the circumſtances of life and death: for obſerving, that, as ſoon as the ſoul was departed out of a man, all motion, reſpiration, nutrition, &c. immediately ceaſed, they concluded that all thoſe functions depended on the ſoul, and conſequently that the ſoul was the form of the animal body, or that which conſtituted it ſuch: that the ſoul was a ſubſtance, independent of matter, nobody doubted; and hence the forms of other bodies were concluded equally ſubſtantial.

But to this it is anſwered, that though the ſoul be that by which a man is man, and conſequently is the form of the human body, as human; yet it does not follow, that it is properly the form of this body of our's, as it is a body; nor of the ſeveral parts thereof, conſidered as diſtinct from each other. For thoſe ſeveral parts have their proper forms ſo cloſely connected with their matter, that it remains inſeparable therefrom, long after the ſoul has quitted the body: thus fleſh has the form of fleſh; bone of bone, &c. long after the ſoul is removed, as well as before.

The truth is, the body does not become incapable of performing its accuſtomed functions, becauſe the ſoul has deſerted it; but the ſoul takes its leave, becauſe the body is not in a condition to perform its functions.

The ancient and modern corpuſcular philoſophers, therefore, with the Carteſians, exclude the notion of ſubſtantial forms; and ſhew, by many arguments, that the form is only the modus or manner of the body it is inherent in.

And as there are only three primary modes of matter, *viz.* figure, reſt, and motion, with two others ariſing therefrom, *viz.* magnitude and ſituation, the forms of all bodies they hold to conſiſt therein; and ſuppoſe the variations theſe modes are capable of, ſufficient to preſent all the variety obſervable in bodies. See Mode.

Many varieties we actually ſee reſult from changes in theſe modes, which may very well paſs for differences of form: thus, an awl only differs from a needle in magnitude; a globe from a cube in figure; and tranſparent glaſs, being pulverized, will reflect the light, and appear white; and yet all the alteration conſiſts in the order and arrangement of the parts; when wheat is ground into flour, all the change conſiſts in a ſeparation of the contiguous parts; and when the flour is baked into bread, what is it but the ſame particles aſſociated again in another manner? By agitating water, a froth is formed; if the agitations be increaſed, the particles will exhale, and form clouds; which being congregated again, return in dew, ſnow, hail or rain; and the ſame water, by the acceſſion of cold, might have been formed into ice. So many different bodies, endued with different qualities, and which the Peripatetics themſelves allow ſpecifically different, ariſe from one and the ſame body, by mere motion and reſt!

The

The philoſophy of ſubſtantial forms, its riſe, uſe, and extent, are ſet in an excellent light by F. Malebranche. But it is needleſs now to enlarge on this ſubject. Forms are uſually diſtinguiſhed into *eſſential* and *accidental*. Though the five modes above mentioned, generally taken, be adventitious; yet, to this or that body, *e. gr.* to fire, or water, they are eſſential: thus, it is accidental to iron to have this or that magnitude, figure, or ſituation, ſince it might exiſt in different ones; yet, to a knife, or hammer, the figure, magnitude, and poſition of parts, which conſtitute it a hammer, or knife, are eſſential, and they cannot exiſt, or be conceived without them. Hence it is inferred, that, though there be no ſubſtantial, there are eſſential forms, whereby the ſeveral ſpecies of bodies become what they are, and are diſtinguiſhed from all others. *Accidental* forms are thoſe really inherent in bodies, but in ſuch manner as that the body may exiſt in all its perfection without them. Such as whiteneſs in a wall; heat in water; a figure of a man in wax, &c.

Forms, again, are diſtinguiſhed into *ſimple* and *compound*: the former are thoſe of ſimple bodies; *i. e.* of ſuch as have but few properties: and the latter are thoſe of more compound bodies; or of ſuch as have more properties.

Thus, *e. gr.* if the form of a hard body be compared with the form of wood, the former may be accounted *ſimple*, and the latter *complex*: inaſmuch as a hard body, conſidered only as hard, has fewer properties than wood. Abſolutely ſpeaking, however, ſimple forms are thoſe of the elements; and compound, thoſe of the mixt bodies.

Some diſtinguiſh forms into *natural* and *artificial*. *Natural* forms are thoſe inherent in bodies, without any thing contributed thereto on the part of man. Such is the form of marble. Whereas *artificial* forms are thoſe ariſing from human induſtry. Such is that of a ſtatue. But this diſtinction is uſeleſs, and does not imply any intrinſic difference in the forms themſelves.

Others, again, diſtinguiſh forms into *primary* and *ſecondary*. *Primary*, or *univerſal* forms are thoſe which originally belong to phyſical and natural bodies; and theſe, they ſay, are extenſion, figure, and organization; figure having reſpect to its external, organization to its internal, and extenſion being common to both. *Secondary* forms are the ſame ſenſible qualities, and ariſe, for the moſt part, from the primary forms. Harris's Philoſ. Arrangements. p. 88.

FORM is alſo uſed in the ſame ſenſe with claſs.

FORM alſo denotes the external appearance or ſurface of a body; or the diſpoſition of its parts, as to length, breadth, and thickneſs. In which ſenſe it coincides with figure.

FORM is alſo uſed for a manner of being, or doing a thing according to rules; *e. g.* this republic has frequently changed its form of government; that is, its conſtitution. Pardons generally expreſs a remiſſion or abolition of a crime, in what form or manner ſoever it be committed. He was admitted doctor in form. Put your argument in form.

FORM, in *Hunting*, denotes the ſeat of a hare; or the place and time when and where ſhe ſquats.

FORM, in *Joinery*, &c. is applied to the long ſeats or benches in the choir of churches, for the prieſts, canons, prebendaries, religious, &c. to ſit on.

Du-Cange takes the name to be derived from hence, that the backs of the ſeats were anciently enriched with figures of painting and ſculpture, called in Latin *formæ & typi*. In the life of St. William of Roſchild, we meet with forms as ſignifying a ſeat for an eccleſiaſtic, or religious, in a choir; and in that of St. Lupicin, we have *formula* in the ſame ſenſe. In the rule of the monaſtery of St. Cæſaria, the nun who preſides over the choir is called *primiceria, vel formari*.

FORM, in *Law*, is applied to certain eſtabliſhed rules to be obſerved in proceſſes or judiciary proceedings. In which ſenſe the word ſtands oppoſed to the ground or matter in diſpute, or the merits of a cauſe. Under this head we may obſerve, that not only the ſubſtantial part, or judicial deciſions of the law, but alſo the formal part, or method of proceeding, cannot be altered but by parliament; for, if once thoſe outworks were demoliſhed, there would be an inlet to all manner of innovation in the body of the law itſelf. The king, it is true, may erect new courts of juſtice; but then they muſt proceed according to the old eſtabliſhed forms of the common law.

Contra FORMAM *collationis, feoffumenti, et ſtatuti*. See CONTRA.

FORM is alſo uſed, in the *Mechanic Arts*, for a kind of mould whereon a thing is faſhioned or wrought.

Such are the hatter's form, the paper-maker's form, &c.

The hatters' form is a large block or piece of wood, of a cylindrical figure; the top whereof being rounded, and the bottom quite flat. Its uſe is, to mould or faſhion the crown of the hat, after the matter thereof has been beaten and fulled. To form a hat, it is neceſſary the wool, hair, &c. be very hot, juſt reeking out of the copper. The paper-makers' form is the frame or mould wherein the ſheets are faſhioned. See PAPER.

FORM, in *Mineralogy*. Mr. Wm. Martin, one of the lateſt and beſt writers on the extraneous foſſils, organic remains or relics of the former race of animated beings and vegetables, of which we can now only find the veſtiges in the ſtrata of the earth, is of opinion, that it is the form only of ſuch relics which can be taken into account in claſſing them into genera and ſpecies. See RELIQUIA.

FORM, in *Theology*, denotes one of the eſſential parts of the ſacraments, being that which gives them their ſacramental nature and efficacy.

The form conſiſts in certain words, which the prieſt pronounces in adminiſtering them. In ſome of the Romiſh ſacraments, the form is deprecative; in our's it is abſolute, or indicative.

The fathers and ancient divines held, that the ſacraments conſiſted of things and words, *rebus & verbis*. William of Auxerre was the firſt who, about the beginning of the 13th century, introduced the terms *matter* and *form* in lieu thereof.

FORM *of Concord*, in *Eccleſiaſtical Hiſtory*. See CONCORD.

FORM *of a Series*, in *Algebra*. See SERIES.

FORM, *Syllogiſtic*, in *Logic*, is a juſt diſpoſition, both of the terms, in reſpect of predicate and ſubject; and of the propoſitions, in reſpect of quantity and quality.

By juſt diſpoſition, we mean ſuch an one, wherein the concluſion follows duly and legitimately from the two premiſes, there being no form where there is no concluſion. See SYLLOGISM.

The diſpoſition of the ſeveral terms, being, as it were, ſo many ſteps or degrees of a ſyllogiſtic form, is called the *figure* of the ſyllogiſm.

The diſpoſition of the premiſes alone, being, as it were another degree, is called the *mode* of the ſyllogiſm. See FIGURE and MODE.

FORM, in *Printing*, or *Printers' form*, is an aſſemblage of letters, words, and lines, arranged in order, and diſpoſed into pages, by the compoſitor; from which, by means of ink and a preſs, the printed ſheets are drawn.

Every

Every form is incloſed in an iron chaſe, wherein it is firmly locked by a number of pieces of wood, ſome long and narrow, and others in form of wedges.

There are two forms required for every ſheet; one for each ſide; and each form conſiſts of more or fewer pages, according to the volume of the book. See PRESS, and PRINTING.

FORM *of Corporeity*, according to Avicenna, and the Scotiſts, is that which conſtitutes body in the generical eſſe of body. That there is ſuch a thing, they prove thus: the human body is a natural body, which cannot be placed in the eſſe of body, but by the form of corporeity: for it is either ſo placed by this, or by the rational ſoul; not by the ſoul, ſince that is ſpiritual; therefore, by the form of corporeity. And the ſame may be underſtood of other bodies: but the later philoſophers ſet this aſide as a chimera.

FORMA, MODO ET, in *Law*. See MODO.

FORMA *Pauperis*, or *in Forma Pauperis*, is when any perſon has a cauſe or ſuit, but is ſo poor that he cannot diſpend the uſual charges of ſuing at law, or in equity.

In this caſe, upon his making oath that he is not worth 5*l*. his debts being paid, and bringing his certificates from ſome lawyer, that he has juſt cauſe of ſuit, the judge admits him to ſue *in forma pauperis*; that is, without paying fees to the counſellor, attorney, or clerk. This cuſtom has its beginning from ſtat. 11 Hen. VII. cap. 12. See COSTS and DISPAUPER.

FORMAL, ſomething that regards the form; or that gives the manner, or form.

The formal cauſe joining itſelf to the material, produces the body or compound.

The ſchoolmen alſo apply the word to any thing which has a kind of form, either eſſential or accidental, at leaſt, in our conception. Thus we frequently hear the philoſophers talk of the formal object of knowledge; and of the formal reaſon of any thing; formal unity, &c.

FORMAL *Cauſe* is defined, by certain philoſophers, to be ſomething implanted in one parcel of matter, whereby it is diſtinguiſhed from all other matter.

For matter is ſuppoſed common to all bodies: conſequently, that they are diſtinguiſhable from one another, does not ariſe from their matter, but from the form which is peculiar to each: hence, what is produced by ſuch cauſe, is ſaid to be formal.

FORMAL *Circle*. See CIRCLE.

FORMAL *Notion*. See NOTION.

FORMAL is alſo uſed in a moral ſenſe, importing poſitive, expreſs, and preciſe.

Thus we ſay, a formal agreement, a formal text, formal anſwer, &c. Formal evidence, ſee EVIDENCE.

FORMALITER, FORMALLY, is variouſly uſed in the ſchools.

Sometimes it is underſtood of the ſubject, when a predicate is therein on account of ſome form: thus, white, formally taken, diffuſes light; *q. d.* the form inherent in this ſubject, *viz.* whiteneſs, is the cauſe why the ſubject diſperſes the light.

FORMALLY has alſo place in ſuppoſitions; a word being formally ſuppoſed, when it is taken for the thing it was intended to ſignify: as, *man is an animal*.

FORMALLY is alſo uſed in the ſame ſenſe with adequately and totally; thus, a ſyllogiſm formally, *i. e.* adequately taken, requires three propoſitions.

FORMALLY is alſo uſed for really, in oppoſition to objectively; thus, a thing is ſaid to be formally ſuch, when it is ſuch in the proper notion of the thing ſpoken of.

FORMALLY, again, is uſed in ſpeaking of the manner where in a thing is contained in another, in oppoſition to virtually and eminently.

FORMALITY, the quality of a form or formula; or that which conſtitutes and denominates them ſuch.

FORMALITY, as defined in the *Schools*, is any manner, wherein a thing is conceived; or, a manner in any object, importing a relation to the underſtanding, whereby it may be diſtinguiſhed from another object.

Thus, animality and rationality are formalities. The Scotiſts make great uſe of formalities, in oppoſition to the virtualities of the Thomiſts.

The Scotiſts hold, that the metaphyſical degrees in man are ſo many formalities, really diſtinct from each other; as *man*, *living*, *animal*, &c. And the ſame they hold of the attributes of God. The Thomiſts, on the contrary, contend that they are really and intrinſically the ſame.

FORMALITIES, in *Matters of Law*, are frequently uſed for the formulas themſelves, or the rules preſcribed for judiciary proceedings. In contracts of ſtrict law, all the formalities muſt be ſtrictly obſerved; and omiſſion of the leaſt formality may ruin the whole convention.

The term is alſo uſed for a certain order, or decorum to be obſerved.

FORMARTEN, in *Geography*, one of the four diſtricts into which Aberdeenſhire in Scotland was formerly divided; the other three being Mar, Buchan, and Gariock. Formarten extends along the coaſt from the river Don to the Ythan, and on the weſt is bounded by a ridge of low hills near Old Meldrum, which ſeparate it from Gariock. It conſiſts partly of a ſtony ſoil, interſected with bogs, and partly of an excellent clay, capable of a high degree of improvement.

FORMATION, in *Geology*, is a term much in uſe with the diſciples of Werner, and other German geognoſtics, and ſignifies ſtrata or maſſes of ſtone, following each other in an uninterrupted order or ſeries, and ſuch as may have been formed by the ſame agent, and under a ſucceſſion of ſimilar circumſtances. This term ſeems generally uſed ſynonymouſly with ſtrata, or depoſitions of matter, but ſometimes ſignifies the particular ſtructure of mountains or large maſſes of particular kinds of minerals. See GEOGNOSY.

FORMATION, in *Philoſophy*, &c. the act of forming, faſhioning, or producing a thing.

FORMATION *of Stones*. See STONES.

FORMATION *of the Tails of Comets*. See COMETS.

FORMATUM PUNCTUM. See PUNCTUM.

FORME', or FORMY, in *Heraldry*. A croſs formé, or formy, is a croſs narrower in the centre, and broad at the extremes: ſo called by Leigh and Morgan, though moſt other authors call it *patée*.

FORMED, or FIGURED *Stones*, among *Naturaliſts*, are ſuch bodies as, being either pure ſtone, flint, or ſpar, are found in the earth, ſo formed, as that they bear a near reſemblance to the external figure of muſcles, cockles, oyſters, or other ſhells, or to plants, or animals.

Authors have been greatly divided as to their origin: the ſeveral opinions ſee under the articles FOSSIL, SHELL, &c.

FORMED *Bachelor*. See BACHELOR.

FORMED, in *Heraldry*, the ſame as ſeated.

FORMEDON, *Secundum Formam Doni*, in *Law*, a writ which lies for him who has a right to lands or tenements by virtue of an entail ariſing from the ſtatute "de donis" of Weſtm. 2. 13 Edw. I. cap. 1. This is in the nature of a writ of right, which is confined only to ſuch as claim in fee-

ſimple;

ſimple; and it is the higheſt action the tenant in tail can have. Finch. L. 267. Co. Litt. 316.

The time of limitation in a formedon, by ſtat. 21 Jac. I. cap. 16. is twenty years; within which ſpace of time, after his title accrues, the demandant muſt bring his action, or elſe is for ever barred.

There are three kinds, *viz. forma donationis*, or *formedon in the deſcender; formedon in the remainder;* and *formedon in the reverter*.

FORMEDON *in the deſcender* lieth, where a gift in tail is made, and the tenant in tail alienes the lands entailed, or is diſſeiſed of them, and dies; in this caſe, the heir in tail ſhall have this writ, to recover thoſe lands ſo given in tail againſt him who is then the actual tenant of the freehold. F. N. B. 211, 212.

FORMEDON *in the remainder*, lies where a man gives land to another for life or in tail, with the remainder to a third perſon in tail or in fee; and afterwards the former tenant dies without iſſue inheritable, and a ſtranger intrudes upon him in remainder, and keeps him out of poſſeſſion. F. N. B. 217. In this caſe, he in remainder ſhall have this writ, in which the whole form of the gift is ſtated, and the happening of the event upon which the remainder depended. This writ is not given in expreſs words by the ſtatute "de donis;" but is founded upon the equity of the ſtatute, and upon this maxim in law, that if any one hath a right to the land, he ought alſo to have an action for the recovery of it.

FORMEDON *in the reverter* lies where there is a gift in tail, and afterwards by the death of the donee or his heirs without iſſue of his body the reverſion falls in upon the donor, his heirs or aſſigns; in ſuch caſe the reverſioner ſhall have this writ to recover the lands, wherein he ſhall ſuggeſt the gift, his own title to the reverſion minutely derived from the donor, and the failure of iſſue upon which his reverſion takes place. F. N. B. 219. 8 Rep. 88. This lay at common law before the ſtatute "de donis," if the donee aliened before he had performed the condition of the gift, by having iſſue, and afterwards died without any. Finch. L. 268.

FORMELLA, a certain weight of about ſeventy pounds, mentioned in the ſtatute of weights and meaſures, 51 Hen. III.

FORMELLO, in *Geography*, a town of Italy; 10 miles N.W. of Rome.

FORMENTARA. See FROMENTERA.

FORMENTOR, CAPE, the N.E. point of Majorca. N. lat. 39° 57′. E. long. 3° 13′.

FORMER, in *Gunnery*, for cartridges, conſiſts of a piece of wood, either cylindrical or flat, according to the ſize of the cannon, &c. for which it is to be employed, or for the material whereof the cartridge is to be made. For making ſmall cartridges of paper, ſuch as are ſuited to muſkets, carabines, piſtols, &c. a cylindrical former of a proper diameter, and about a foot in length is neceſſary; this ought to be made of lignum vitæ, or heart of crab-tree, or ſome ſuch very ſolid wood, turned perfectly ſmooth, and armed at its ſummit or upper extremity with a ſtout braſs or copper ferril. The other extremity is either flat or concave, according as the cartridges are to be made either *blank* (*i. e.* light) or *heavy* (*i. e.* with a ball in each). When blank cartridges are to be made, the flat-ended former is to be uſed, the paper being wrapped round, under the guidance of a turned ring or groove, to keep it to a proper height; when the end being properly lapped over in regular folds, is placed downward on a board, and the former, ſtanding perpendicularly, is ſtruck ſeveral times forcibly with a mallet; ſo that the laps of the paper may be fixed in their ſituations, and not be liable to open when the cartridge caſe may be taken off the former to be handed over to thoſe whoſe duty it may be to pour into each the allotted quantity of gunpowder.

Heavy, that is, ball-cartridges, are made with a former, of which the lower extremity is nearly ſemi-ſpherically concave, ſo as to allow the ball to fit in while the paper is paſſed round. That being done, a piece of fine, but tough twine is paſſed in a double hitch over the paper, cloſe to the ball, and drawn very tight; thus ſecuring the ball from falling out, and enabling it to retain the gun-powder. When properly managed, the end of the paper will form an inverted cup, of which all but about the third of an inch ſhould be cut away with a pair of ſciſſars; when the former, being as before placed perpendicular on the board, and ſtruck with the mallet, the cup will be flattened, at the ſame time that the ball is ſettled cloſe down to the ligature; the former may then be withdrawn.

The former for a cartridge of any ſize, when made with paper, may be on the ſame principle, the ſize being ſuited to the nature of the piece for which the cartridges may be preparing.

When woollen cartridge-caſes are to be made, a flat former, not unlike a taylor's ſleeve board, is needful; the width of the former being proportioned to the calibre of the cannon, and its length according to the uſe to which it is to be put: thoſe for ſalutes, &c. wherein ſmall charges of powder are required, being leſs capacious than ſuch as are intended for ſervice, but eſpecially for battering in breach. The following lengths of cartridges will ſerve to ſhew the requiſite lengths of the ſeveral formers; obſerving that one end is at right angles with the two ſides, which of courſe are parallel, and, that the other is ſemi-circular: the edges are every where duly rounded off.

TABLE for the lengths of formers for the cartridges uſed in cannon.

Nature of the piece of Ordnance.		Paper. Feet.	Paper. Inches.	Flannel. Feet.	Flannel. Inches.

FORMERY, in *Geography*, a town of France, in the depart nent of the Oiſe, and chief place of a canton in the diſtrict of Beauvais; 9 miles N.W. of Gerberoy. The place

place contains 1,433, and the canton 10,050 inhabitants, on a territory of 220 kiliometres, in 24 communes.

FORMEY, John Henry Samuel, in *Biography*, was born at Berlin in 1711. His family was originally of Champagne, and his father was a refugee on account of his religious principles, at the revocation of the edict of Nantes. He was educated at the royal French college for the church, and was ordained miniſter before he had completed his twentieth year. He was choſen one of the officiating miniſters of the French congregation in Berlin; in 1737 he was appointed profeſſor of eloquence in the French college, and in 1739 ſucceeded to the philoſophical chair of the ſame college. On the reſtoration of the Royal Academy of Sciences and Belles Lettres at Berlin in 1744, M. Formey was made ſecretary to the philoſophical claſs, and four years afterwards, at the inſtance of the preſident Maupertuis, he was created ſole and perpetual ſecretary of the academy, which poſt he held nearly fifty years. He was admirably qualified for the office, and ſo was regarded by foreigners as well as by his own countrymen. He was accordingly aſſociated to a number of foreign learned bodies, as thoſe of London, Peterſburg, Haarlem, Mantua, Bologna, and many others in Germany, and he was perſonally acquainted with ſeveral of the moſt eminent and illuſtrious characters throughout Europe. Beſides his academical employments, he had the management of various other concerns. He was agent or ſecretary to the dowager princeſs of Wirtemberg: he filled ſeveral offices in the French colony at Berlin, and at length became a privy counſellor in its ſuperior directory. He was twice married, and by his ſecond wife had many children, ſeven of whom ſurvived him. He died in the month of March 1797, at the great age of eighty-five years and eight months. The printed works of M. Formey were ſo numerous, that he is ſaid to have been in connection with fifty bookſellers. There is ſcarcely a department in the fields of ſcience and literature which he had not cultivated; and his early occupation as a journaliſt, which he began in 1733 with Beauſobre in the Bibliotheque Germanique, had given him a very extenſive acquaintance with books on all ſubjects. In theology, he wrote "Le Philoſophe Chretien:" he defended the cauſe of revelation againſt Diderot and Rouſſeau. He took an active part in the Encyclopædia of Yverdun, and wrote various popular pieces on morality, and elementary works for young people. As a member of, and contributor to the academy, he read a number of memoirs, as well on popular as on high philoſophical ſubjects, ſuch as the doctrines of liberty and neceſſity: the demonſtration of the exiſtence of a God, &c. In all theſe there are a clearneſs and preciſion, an eaſy and flowing ſtyle, and a freedom from that dogmatiſm which is very diſguſting when aſſumed upon ſubjects of ſo much doubt and difficulty. Gen. Biog.

FORMIÆ, in *Ancient Geography*, a town of Italy, in Latium, N. of Capua, and W. of Minturna. Mola di Gæta was built on its ruins. Some have ſuggeſted that it was founded by the ſavage people called Leſtrigones; however this be, it was very conſiderable in the time of the Romans. Horace calls it "Mamurrarum Urbs," from the name of a diſtinguiſhed family which dwelled in or near it. Near this town was the country-houſe of Cicero, called his "Formianum," and not far from hence he was aſſaſſinated by the emiſſaries of Antony. (See Cicero.) The place in which this atrocious deed was perpetrated was diſcovered by the Abbé Chaupy by means of a monument which he found on a private road that led to the ſea, whence Cicero meditated his eſcape. Horace compares the wine made from the grapes of the Formian hills with the Falernian.

FORMIATE. See Formic *Acid*.

FORMIC Acid, in *Chemiſtry*, ſo denominated from the inſect from which it is obtained. Chemiſts are not unanimous in their opinion reſpecting this acid; ſome of them contend that it is no other than the acetic or malic acid, and others maintain that its properties are diſtinct from thoſe of all other acids, and therefore that it is an acid *ſui generis*. It was noticed nearly a century and half ago in the Philoſophical Tranſactions by Mr. Ray, who gave an account of the experiments of Mr. Fiſher on the acid juice which is given out ſpontaneouſly by ants, and which they yield when diſtilled. Since that period many experiments have been made by Margraff, Richter, Deyeux, Fourcroy, Vauquelin, and others; of whom the laſt two concluded that the formic acid was a mixture of the acetic and malic acids. Suerſen was induced to examine the ſubject with much attention, and from his experiments in 1804, he inferred that formic acid contains no malic acid, and that its properties are very different from the acetic. This chemiſt had recourſe to the method propoſed by Margraff, and corrected by Richter to obtain the formic acid pure. He infuſed a quantity of red ants, *formicæ rufæ*, in thrice their weight of water, and put the mixture in a ſilver ſtill; drew off the water by diſtillation, till a burnt ſmell began to be perceived; he then ſaturated the water in the receiver with pot-aſh, and evaporated to dryneſs. The maſs thus obtained was mixed with as much diluted ſulphuric acid as was ſufficient to ſaturate the potaſh, and diſtilled to dryneſs in a retort. The liquid, which came over, was again rectified by moderate heat to get rid of any remaining portion of ſulphuric acid; and the reſult was ſuppoſed to be pure formic acid. It is colourleſs like water; its ſmell is peculiar to itſelf, and different from that of acetic acid; its taſte is acid; it reddens vegetable blues; and ſo alſo will the juice which is given out ſpontaneouſly by the inſect in paſſing over the corollæ of blue flowers. The ſpecific gravity of formic acid is 1.11, whereas the moſt concentrated acetic acid is only 1.08. It is not ſuſceptible of being brought to a ſtate of cryſtals, and it will not neutralize ſo large a quantity of alkali as the acetic acid. This acid flies off in the form of vapour; ſmelling ſomething like muſk; deſtroys animal life under the gaſeous form; is capable of ſerving economical purpoſes like vinegar; is decompoſed by great heat, and forms ſalts with earth in alkalies and metallic oxyds, which are cryſtallizable and not deliqueſcent. Theſe have been denominated formiates by thoſe who admit the formic as a diſtinct acid, but by thoſe who oppoſe this theory the formiates are ſuppoſed to be compounds of the acetates and malates together, with a portion of animal matter, the nature of which is not perfectly known. The quantity of acid contained in ants exceeds what is found in any other known part of the animal creation. Theſe inſects exhale the acid whether irritated or not, ſo that the ſame changes, produced on flowers by known acids, take place when they are laid in the tract of ants, and it has been conjectured that part of the irritation cauſed by their bite is produced by the inſertion of a portion of their native acid.

FORMICA, in *Entomology*, a genus of the hymenopterous order, poſſeſſing, according to Linnæus, the following eſſential character: a little upright ſcale between the thorax and the abdomen; males and females furniſhed with wings, and the neuters apterous, or wingleſs.

Geoffroy propoſes in addition to the above character, to

diſtinguiſh the inſects of this genus from the ſtructure of the antennæ, theſe, as he obſerves, being in the true formicæ, elbowed or broken into an angle in the middle, and having the firſt joint longer in proportion than the others; the ſtemmata or falſe eyes three in number, and the abdomen joined to the thorax by means of a ſhort pedicle, or ſtalk.

This character is further improved by Schæffer, who deſcribes the formicæ as having the mouth armed with jaws, the wings incumbent, and the tarſi compoſed of five articulations.

Fabricius defines the genus with ſtill more preciſion, from the ſtructure of the organs, or parts which compoſe the mouth; according to this author, the feelers are four in number, unequal, with cylindrical joints placed at the tip of the lip, which is cylindrical, and almoſt membranaceous, and the antennæ filiform.

In the Gmelinian edition of the Syſtema Naturæ, the Fabrician definition is united with that before aſſigned to the genus formica by Linnæus.

La Marck explains the genus ſomewhat differently, and by the adoption of his character, ſeveral of the Linnæan and Fabrician formicæ are excluded. This writer lays down the eſſential character as follows; antennæ filiform and broken, the firſt joint very long; feelers unequal, the anterior pair longer; mandibles ſtrong; tongue ſhort, concave and truncated. To this is added, as a ſecondary character, that the abdomen is attached to the corſelet by a pedicle, bearing a ſmall ſcale, or vertical knob; and that of each ſpecies there are three kinds, males, females, and neuters, which latter are without wings. The larva deſtitute of feet.

It will not be amiſs in this place to remark that the ſpecies of formicæ known to Linnæus, or at leaſt deſcribed by that naturaliſt, do not amount to twenty, a number nearly doubled by Fabricius in his "Species Inſectorum," as he there deſcribes altogether thirty-ſeven; and this number has been again progreſſively augmented in his later publications to about ninety ſpecies. Thus it will be perceived that Fabricius and not Linnæus is the firſt deſcriber of the far greater number of thoſe ſpecies which are inſerted in the laſt edition of the Syſtema Naturæ, and it muſt be at the ſame time obſerved that it is principally to his labours we ſtand indebted for our knowledge of thoſe kinds which are peculiar to extra-European climates.

Since the time of the above writers, the hiſtory of this curious tribe of inſects has engaged the attention of other continental entomologiſts, among the principal of whom we ſhould mention Latreille. This author deſcribes only a few new ſpecies, yet he enters more minutely on the ſubject of claſſification in this family than either of his predeceſſors. From the reſult of his obſervations it appears neceſſary to divide the formicæ of Linnæus and Fabricius into two, if not a greater number of genera, and beſides that to form ſeveral ſubdiviſions of thoſe which ought to be retained under the original deſignation of formica. The moſt obvious diſtinction conſiſts in the diſſimilar ſtructure of the antennæ, theſe in one tribe terminating in a maſs or club, and being in the other nearly ſetaceous; in the latter the firſt joint is very long, the ſecond almoſt conic, and the laſt of the ſame bulk as the foregoing, or rather leſs. The inſects which compoſe this ſection are further diſtinguiſhed by other characters, which ſeem to concur in forming a natural line of ſeparation between the two genera, the moſt material of which appears however to conſiſt in the ſtructure of the antennæ.

Latreille at one time propoſed to comprehend the firſt mentioned tribe as a diſtinct genus under the name of cryptocerus, allowing the others to remain under the original appellation of formica. In an arrangement ſubſequently publiſhed by the ſame author, he retains the whole as one family, which he calls formicariæ, and under this is included no leſs than eight genera. The ſpecies of formicæ, herculanea, rufeſcens, hæmatoda, clavata, hamata, and cephalotes are conſidered generically diſtinct from each other, and are referable to the ſeveral newly inſtituted genera of Latreille in the following order; herculanea, with 4-punctata, and rufa, belong to the genus formica; rufeſcens to polyergus; hæmatoda to odontomachus; clavata to ponera; hamata and guloſa to eciton; and cephalotes with rubra to myrmica; the two remaining genera of this family are cryptocerus and dorylus. Several of theſe genera are ſubdivided into two or more ſections, which altogether render the arrangement rather more diffuſe than will be deemed perhaps in any manner requiſite by other naturaliſts.

The formicæ are called among us piſmires, ants, or emmits. They live, for the moſt part, in large ſocieties; are proverbially an induſtrious race of creatures; and, like the bees, their ſpecies are invariably compoſed of three kinds, the males, females, and neuters. The different ſpecies are diſperſed throughout every part of the known world: many inhabit woods, where they eſtabliſh themſelves in immenſe colonies, in the trunks of decayed trees, or in deep ſubterranean cavities, which they either conſtruct for themſelves, or ſeize from others; for colonies of ants are frequently met with in cavities of the ground, which are known to be the burrows of rats, rabbits, and other quadrupeds, whoſe habitations theſe troubleſome intruders have probably rendered untenable to the original occupiers. Some form their neſts in the earth, beneath the ſhelter of a heap of ſtones, or under a tree, among the ramifications and branches of the root; while others occupy the more open places, in the fields or plains, and ſo contrive their habitations that the ſummit riſes in a cone or hillock, which we call an ant-hill, to the height of one, two, or three feet; and in hot climates, even more above the ſurface of the ground. There are ſpecies which in a ſimilar manner form neſts in the ſands; but theſe are not numerous. The interior of theſe neſts is generally ſpacious, and adapted for the reception of thoſe myriads of creatures which compoſe each diſtinct ſociety. Thoſe which reſide in trees provide themſelves with an habitation, by ſelecting ſuch as are already rotten, and excavating the interior to the dimenſion required. Others, and thoſe in particular which live in the hillocks, conſtruct the walls of their cones with dry vegetable ſubſtances, ſuch as the leaves of fir trees, and other evergreens, dried tendrils, twigs, and ſtalks, or other ſimilar materials, intermixed with earth and clay. The interior exhibits a number of apartments or paſſages, the middle one of which may be conſidered the principal, as being the nurſery for the larvæ or young; other parts are allotted to the males and females; and the more open ſpaces to the neuters.

The conſtruction of theſe neſts, in common with every other laborious occupation, is the buſineſs of the neuters, as among the bee-tribe. While the latter are employed in drudgery, in providing the ſociety with a ſufficient ſtock of proviſion, and in the various toil incidental to the feeding and rearing the young, the females ſit in inactivity, and never quit the neſt, except to indulge in the ſofter paſſions with the males. Linnæus believed their amours were conducted within the neſt, an idea contradicted by the more recent

recent obſervations of other naturaliſts. On this occaſion they leave the neſt, and under favour of the darkneſs which a ſummer evening affords, retire to a ſhort diſtance, whither the males follow; and in ſuch ſituations the ants are frequently ſeen covering the ground in pairs for a pretty conſiderable ſpace. The ſeaſon of coupling varies in different ſpecies from the beginning of ſummer to the end of autumn.

After this union of the ſexes, the males die, or at leaſt never return to the neſt; the females, on the contrary, either return of their own accord, or are carried thither by the working ants, and are attended with the utmoſt care and tenderneſs. The eggs they depoſit are conveyed to their proper receptacle, and, when hatched, become the objects of their deepeſt ſolicitude. The eggs are ſmall, roundiſh, and of a yellowiſh-white colour. The larvæ are white, thick, and ſhort, and their body compoſed of twelve rings. In the nymph or pupa ſtate, thoſe ants, which when produced will be deſtitute of a ſting, are entirely naked; while the others are enveloped in a ſilken cone. The females are much larger than the males.

The working ants wander about all day in ſearch of food, or materials for the neſt; and aſſiſt each other, when the load is too heavy for one or more that have attempted to move it. The eggs and larvæ are daily brought out of the neſt by them, and expoſed to the warmth of the ſun; and the larvæ fed till they aſſume the pupa form. When in ſearch of proviſion, they will not ſcruple to attack any inſect, however conſiderable in ſize, and, by their united ſtrength, have little difficulty to overcome their victim. They alſo attack and devour ſmall quadrupeds, birds, and reptiles, when they find them in a helpleſs ſtate, incapable of defending themſelves; and which, in the end, muſt be conſidered as the fate of many. In ſhort, they prey on food of every kind, whether animal or vegetable. Some ſpecies are, however, moſt injurious to the former, and others to the latter; though, when preſſed with hunger, they devour either indiſcriminately.

In the evening, when their labour is over, the ants are ſaid to make their repaſt of whatever proviſion they have collected in the courſe of the day; for their care and foreſight, in laying up a ſtore of proviſion againſt the winter, are no other than pleaſing fictions, which, however they amuſe the fancy, have no exiſtence in reality. During the winter, they either become torpid or die. The ants are particularly fond of the aphides, or lice which infeſt plants; and are, in their turn, the favourite food of birds and various other animals.

Ants ſwarm in every region of the globe. In northern countries, and more eſpecially thoſe which abound in woods, theſe inſects are exceedingly troubleſome. The ravages of theſe creatures are not, however, to be compared with thoſe of the ant-tribe which inhabit warmer climates. The latter are oftentimes the ſcourge of thoſe countries which they inhabit. In Africa it is well known that proviſion of every deſcription, and even clothes and various articles of furniture, are oftentimes deſtroyed by theſe creatures. The American iſlands ſwarm with them, as well as Africa, and South America. The damage occaſioned by the ants, in the ſugar plantations of Grenada, about the year 1777, affords a memorable proof of the tremendous powers which theſe apparently inſignificant creatures poſſeſs to do miſchief: it was ſo exceſſive, that it was deemed expedient to burn down the whole of the ſtanding crops of canes, and turn up the earth throughout the plantations, in order to deſtroy thoſe ants which had fixed their habitations in the canes, and at their roots. Theſe were to be replaced by new crops: and if that remedy proved ineffectual, it was determined to abandon the culture of the canes altogether. After ſuſtaining conſiderable loſs, and having in vain endeavoured by every means to exterminate the legions of ants with which the country was infeſted, without reſorting to this final remedy, the inhabitants were, however, at length very fortunately relieved by the ſetting in of very heavy rains, which checked the ants in their career of devaſtation, and deſtroyed immenſe numbers of them. The ants in thoſe parts are always numerous; but, on this occaſion, they appeared ſuddenly in ſuch bodies, that nothing could reſiſt them. The country, in many parts, was literally covered for the ſpace of miles with them. They deſcended the hills in torrents; the plantations were every where filled with them, as well as every road and avenue leading to them. Numbers of the domeſticated quadrupeds periſhed. Rats, mice, and reptiles of every kind, became an eaſy prey to them; and even the birds, which they attacked wherever they alighted, till they were ſo haraſſed as to fall at laſt within their power. Streams of water retarded their progreſs only for a ſhort time: the foremoſt columns puſhing boldly into the water to certain death, and there periſhing, formed at length an embankment, which dividing the waters, afforded means for the reſt to paſs over in ſecurity. Even fire itſelf, which will oftentimes deter the moſt ferocious beaſts of prey in their attacks, was in vain employed on this occaſion. Fires were lighted in the routes which, from their courſe along the hills, it was obvious they would purſue; nor did this divert their track: they precipitated themſelves into the fires in ſuch bodies as to extinguiſh them; and though many by this means periſhed, the reſt were enabled to continue their march unhurt.

The appearance of the ants in leſs formidable bodies is indeed eſteemed rather a benefit than diſadvantage, in thoſe countries; becauſe they aſſiſt, and in a very material degree, in the deſtruction of ſnakes, and other venomous reptiles, when they can ſeize on them by ſurpriſe. We are aſſured by Mad. Merian, that the ſpecies cephalotes is called in Surinam the ants of *viſitation*, as they appear only at certain ſeaſons, or about once in two or three years. Its multitudes receive a cheerful welcome from the natives, who throw open the doors of their houſes to admit them: the ants enter, traverſe every part of their dwellings, and, after deſtroying the rats, mice, ſcorpions, kakerlacs, or cockroaches, and other vermin ſecreted therein, again take their departure.

Ants may be eaſily killed by means of arſenic, kneaded with proviſion of any kind, and which being thrown into the neſt, will be greedily conſumed by them. The ſting of the ant is very ſharp and painful, the ſevere ſenſation of which may be abated by the application of a mixture of oil and honey. Such ants as poſſeſs no ſting are, nevertheleſs, capable of exciting a painful puſtule, by means of an acrid juice which they diſcharge upon the ſkin: this juice proceeds from the mouth, contrary to the vulgar ſuppoſition that it is emitted from the vent; and the pain occaſioned by which may be abated by an application of oil and honey, as before mentioned.

A very grateful acid is procured from ants by diſtillation. See FORMIC *Acid*.

The ants are probably more numerous, in reſpect to ſpecies, than we are at preſent aware: the following appear to be the moſt material of thoſe already deſcribed.

Species.

HERCULANEA. Black; abdomen ovate; legs ferru-

 ginous.

ginous. Linn. Fn. Suec. *Formica magna*, ib. *Formica magna hyppomyrmex*, It. Goth. *Formica maxima*, Ray.

Large; lives in the trunks of decayed trees in Europe.

Compressa. Black; thorax compreſſed; tip of the antennæ and thighs rufous; head very large. Fabr.

Native of Tranquebar. The abdomen is ovate; the ſcale entire; thorax immaculate.

Smaragdina. Green; thorax lineated with yellow. Fabr.

Inhabits India, and is of a large ſize; the antennæ reddiſh at the tip; wings large and white, with ferruginous nerves.

Rufipes. Hairy, black; legs rufous. Fabr.

Deſcribed from the Bankſian cabinet. The head is large, ovate, rough with ferruginous hairs; antennæ brown at the tip; ſcale of the petiole ovate-obtuſe.

Bicolor. Black; ſcutel, abdomen, and legs ferruginous. Fabr.

Large; inhabits Barbary.

Erythrocephala. Deep black; head rufous; ſcale of the petiole double. Fabr.

Native of New Holland. The head large and oblong; antennæ rufous; thorax filiform; legs black, at the ends rufous.

Barbara. Deep black; head, antennæ, and ends of the legs ferruginous; petiole with two tubercles. Fabr.

Inhabits Africa; ſize that of herculanea; head large; firſt joint of the antennæ large, and black.

Didyma. Black; abdomen greyiſh; ſcale of the petiole double. Fabr.

An European ſpecies found chiefly in Italy. The ſize is moderate; antennæ pitchy; thorax gibbous; abdomen covered with cinereous down; ſcale double, or widely emarginate; legs black.

Viatica. Ferruginous, abdomen ovate and black. Fabr.

The mandibles are blackiſh at the tip; thorax compreſſed, ferruginous with a ſingle tubercle; hind legs very long with brown ſhanks. This ſpecies inhabits Spain, and is the ſame ſize as the laſt.

Pallipes. Deep black and gloſſy, antennæ and legs whitiſh. Fabr.

Small; head ſmall and roundiſh; thorax gibbous; ſcales of the petiole truncated, and nearly emarginated; wings white. Native of Cayenne.

Ægyptiaca. Black; thorax rufous, two-toothed behind; petiole with two tubercles. Fabr.

Head large, and brown; antennæ ferruginous; thorax compreſſed; legs ferruginous with ſub-clavated thighs; a ſmall ſpecies found in Egypt.

Binodis. Black; head very large and rufous; petiole of the abdomen bituberculated. Fabr.

Native of Egypt; legs rufous; thighs ferruginous.

Rufa. Black; thorax compreſſed, and with the legs ferruginous. Fabr. Thorax compreſſed, entirely ferruginous, head and abdomen black. Linn.

Inhabits Europe.

Pubescens. Black; abdomen pubeſcent. Fabr.

Native of Calabria and Hungary. In ſize reſembles the laſt.

Nigra. Gloſſy-black; tail piceous. Degeer.

An European inſect.

Fusca. Greyiſh-brown and poliſhed; antennæ and legs ferruginous; wings white. Degeer.

Inhabits Europe.

Flavescens. Yellowiſh; abdomen darker, with a black dorſal line. Fabr.

Native of Cayenne. In this ſpecies the ſcale of the petiole is entire.

Melanocephala. Pale; head and back of the thorax black. Fabr.

Like the laſt this inſect inhabits Cayenne; it occurs in immenſe numbers at certain ſeaſons, and commits vaſt depredations, conſuming and deſtroying every kind of proviſion.

Rubra. Teſtaceous; eyes and dot under the abdomen black. Degeer.

An European ſpecies.

Cinerascens. Black; head rufous; abdomen greyiſh. Fabr.

A large ſpecies found in Tranquebar; the head is rufous, mandibles and antennæ black; abdomen ovate, greeniſh-grey, with a black angle behind the middle; wings duſky.

Foetens. Oblong, black; tail rufous; ſcale of the petiole ſomewhat cylindrical and obtuſe. Fabr.

Named fœtens, from its offenſive ſmell; the ſpecies is of a large ſize, preys on other ants, and inhabits Guinea.

Elongata. Oblong, rufous; abdomen and legs paler. Fabr.

A ferocious ſpecies found in Tranquebar; the head is large, mandibles black; thorax elongated and compreſſed; ſcale forming an ovate tubercle in the middle of the petiole.

6-Guttata. Oblong, black; abdomen with three dots each ſide; antennæ and legs rufous. Fabr.

Inhabits Santa Cruz; the mouth is rufous; ſcale ovate, obtuſe and entire; wings whitiſh, with a marginal black ſpot.

Albipennis. Oblong, pale; thorax black behind; abdomen reddiſh. Fabr.

Inhabits ſame country as the former; the ſcutel is white; ſcale of the petiole ovate, gibbous; wings white with a black marginal dot.

Rufibarbis. Oblong, black; mouth and thorax rufous. Fabr.

Native of France.

Obsoleta. Above black; beneath red, teſtaceous; abdomen ſub globular. Fabr.

Leſs than Formica rufa, and inhabits Europe.

4-Punctata. Thorax compreſſed and ferruginous; abdomen black, with four ſnowy dots. Fabr.

Inhabits Alſace. The head is black; antennæ ferruginous; ſcale of the petiole ſhort, obtuſe; legs ferruginous, thighs black.

Virescens. Pale; head and abdomen greeniſh. Fabr.

Deſcribed from the Bankſian cabinet. The petiole is long, with a ſmall raiſed tubercle. This inſect inhabits New Holland.

Saccharivora. Black; antennæ, mandibles, and legs rufous. Brown Jam.

A native of the American iſlands; and is very deſtructive to the ſugar-cane, in which it forms its neſt.

Maculata. Black; poſterior part of the thorax and thighs ferruginous; abdomen with pale ſpots at the ſides. Fabr.

Inhabits Africa; the head is large; mandibles with many teeth; antennæ piceous at the tip; abdomen ovate and hairy.

Antiguensis. Teſtaceous; abdomen black at the tip, the petiole with two tubercles. Fabr.

Native of Antigua.

Guineensis. Ferruginous; abdomen black; legs yellowiſh. Fabr.

A ſmall

A ſmall ſpecies found in Guinea.

Omnivora. Thorax rough, with raiſed dots; petiole with two tubercles; body teſtaceous; abdomen very minute. Degeer.

Native of Surinam.

Flava. Yellow; abdomen ovate and pubeſcent. Degeer.

An European ſpecies.

Caespitum. Black; petiole of the abdomen with two tubercles; ſcutel bidentated. Linn.

In dry meadows under moſs in Europe; the winged ants of this ſpecies fly abroad in ſwarms like the day-fly, when the weather is ſerene.

Tuberum. Rufous; head black; abdomen with a black band, the petiole with two tubercles. Fabr.

Inhabits Sweden; leſs than the former; the antennæ black at the tip, and the thorax bidentated behind.

Vagans. Rufous; head, and back of the abdomen brown; thorax two-ſpined behind; petiole with two tubercles. Fabr.

Twice the ſize of the former; the head globular; antennæ ferruginous. This ſpecies inhabits Saxony.

Acervorum. Rufous; head and abdomen black; thorax two-ſpined behind; petiole with two protuberances. Fabr.

Reſembles the laſt; the antennæ and mandibles rufous; legs ferruginous.

Native of Denmark.

Unispinosa. Black; antennæ and legs rufous; ſcale of the petiole, with a ſingle ſpine; mandibles projecting, and parallel. Fabr.

Inhabits Gaudaloupe. The body is elongated; head large, grooved in the front; abdomen ovate and black; legs red.

Grossa. Blackiſh; thorax bidentated under the ſcutel; abdomen large and globular. Fabr.

Native of Cayenne.

This ſpecies is large; the antennæ are pitchy, with the tip grey; head pitchy, ſub-ſpinous each ſide; wings ferruginous.

Australis. Black; thorax unarmed; ſcale of the petiole with two ſpines. Fabr.

Native of New Holland. The body entirely covered with cinereous down.

Bidens. Thorax with two-toothed tubercle; head ovate; antennæ ferruginous; the firſt joint black. Degeer.

Inhabits Surinam.

Biscutata. Thorax bidentated; ſcale of the petiole double. Fabr.

Head pointed each ſide behind; abdomen globular, with a black dorſal line; wings ſub-ferruginous. Native of Cayenne.

Clavata. Black; thorax two-toothed; petiole one-toothed beneath. Fabr.

A large ſpecies found in India; the thorax is gibbous; the petiole with a large tubercle, and ſpine beneath; abdomen ovate, the firſt ſegment globular.

Arenaria. Thorax impreſſed behind, and bidentated; body black; ends of the legs pitchy. Fabr.

Inhabits the moveable ſands of Barbary. The head is large and ovate; thorax compreſſed; the petiole with two tubercles; abdomen ſomewhat globular and downy.

Attelaboides. Black; thorax two-ſpined; head tapering behind; legs ferruginous. Fabr.

A Braſilian ſpecies in the Bankſian cabinet; the head is rough and black; thorax ſlender, black; abdomen brown and downy.

Megacephala. Thorax two-ſpined behind; ferruginous; abdomen black; head very large. Fabr.

Inhabits the iſle of France. The ſpecies is ſmall; head ovate, and larger than the whole body; antennæ and legs ferruginous; petiole with two tubercles.

Ammon. Thorax armed with two ſpines; petiole of the abdomen with two incurvated ſpines. Fabr.

Native of New Holland. The head is ſmall and ovate; thorax and abdomen black, with gold down on the back; legs black.

Bihamata. Thorax four-ſpined; petiole of the abdomen with two curved ſpines. Drury.

The head is ſmall and round; the antennæ long; abdomen ſub-globular, black at the baſe, ferruginous; legs long and black; thighs ferruginous. Inhabits India.

Militaris. Thorax bi-ſpinous before; ſcale of the petiole armed with four ſpines. Fabr.

An African ſpecies. The head is large; gibbous, black, and carinated each ſide between the antennæ; antennæ globular, black, and downy; wings brown.

4-Dens. Thorax quadridentated; body black; head with a double carinated ridge. Fabr.

Native of Cayenne. The ſpines on the thorax placed two before, and two behind.

Sex-dens. Thorax armed with ſix ſpines; head very large, double, and armed with a ſpine each ſide behind. Linn.

Inhabits America.

Cephalotes. Thorax four-ſpined; head large, double, and armed with a ſpine each ſide behind. Linn.

Native of South America, which it inhabits in prodigious number, and is extremely deſtructive in the plantations.

Atrata. Thorax four-ſpined; body black; head depreſſed, margined and armed behind with two ſpines. Linn.

Inhabits ſame country as the former, and is like that ſpecies exceedingly injurious.

Gulosa. Rufous; abdomen black at the tip, the firſt ſegment contracted; mandibles projecting. Fabr.

An Auſtralaſian ſpecies.

Forficata. Brown; abdomen pubeſcent, and black, the firſt ſegment contracted; mandibles projecting. Fabr.

Head large and flat; mandibles forked and toothed within; thorax compreſſed in the middle; petiole with a globular tubercle; legs dull ferruginous. Inhabits New Holland.

Maxillosa. Thorax ſix-toothed; head yelloviſh, the mandibles as long as the head. Fabr.

Native of India; the head is large, and abdomen brown.

Rostrata. Thorax compreſſed, three-toothed before; mandibles projecting and incurved. Fabr.

A ſmall ſpecies found in Cayenne.

Hamata. Ferruginous; head very large and pale; mandibles projecting and hooked. Fabr.

Head with a ſmall conic ſpine each ſide at the baſe; mandibles longer than the head, black and hooked at the tip, the baſe ferruginous; petiole with two tubercles.

Hæmatoda. Scale of the petiole conic, and very acute; head nearly double, the mandible projecting. Linn.

The mandibles are toothleſs, and of a rufous colour; the head reddiſh; thorax unarmed and black; wings hyaline. This ſpecies inhabits America.

Pharonis. Rufous; abdomen browniſh. Linn.

A very minute ſpecies found in Egypt.

Salomonis. Red; abdomen black and ſomewhat villous. Linn.

Native of Egypt and Arabia.

Foetida. Petiole with tranſverſely compreſſed tubercles; firſt ſegment of the abdomen contracted; mandibles projecting. Linn.

The head is black with three raiſed dots, the abdomen and legs hairy. This inhabits America.

Vaga. Black; abdomen ovate and hairy. Scop.

Native of Europe, and lives in decayed trees under the bark.

Venosa. Head and thorax black; abdomen cylindrical and brown; ſcale of the petiole thick and entire; legs teſtaceous; wings white with teſtaceous veins, and a brown marginal ſpot. Linn.

Country unknown.

Melanopis. Rufous; eyes black; abdomen brown on the back; ſcale of the petiole entire. Linn.

This and the four following ſpecies are natives of Europe.

Glabra. Black; glabrous; ſcale of the petiole bidentated; inciſures of the abdomen whitiſh; legs rufous. Linn.

Testacea. Teſtaceous-brown, and ſomewhat downy; antennæ and legs brown; wings white with a ferruginous baſe. Linn.

Fuscescens. Black; head as wide as the abdomen; ſcale of the petiole very ſhort; mouth, antennæ, and legs reddiſh-brown. Linn.

Ruficornis. Head and thorax black; abdomen brown; jaws, antennæ, and legs teſtaceous; wings hyaline.

Formica-*leo*, the *ant-lion*, the name given by authors to a very remarkable ſpecies of inſect, which is, in its perfect ſtate, a winged creature, approaching to the nature of the *libellulæ*, or dragon-flies; but in its prior ſtate of a creeping animal, has a wonderful art and addreſs in catching its prey. It is in this ſtate that it is known by the name of formica-leo, as it chiefly feeds upon ants. See Myrmeleon.

Formica, literally *an ant*, has been applied by the old medical writers to a ſpecies of wart, of a black colour, and with a broad ſeſſile baſe, which Foreſtus obſerves, when it is removed by exciſion, undergoes much pain, reſembling that ariſing from the ſtinging of ants, whence it has received its name. This ſpecies of ſenſation is alſo denominated *formication*, *formicatio*, and by the Greeks μυρμηκιασις, *myrmeciaſis*, from μυρμηξ, *an ant*. The term *formicatio* is likewiſe applied to a ſenſation occaſionally occurring in the ſkin, as if ants or other ſmall inſects were creeping upon its ſurface. See Foreſti Opera, lib. xxiii. obſ. 9.

Formica, among *Sportſmen*, the name of a diſeaſe incident to ſpaniels. See Spaniel.

FORMICATIO. See Formica.

FORMICATION, a term uſed among *Builders* for arching or vaulting.

FORMICHI, in *Geography*, a cluſter of ſmall iſlands and rocks in the Mediterranean, near the coaſt of Italy, between Monte Chriſtio and Pianoſa. N. lat. 42° 40′. E. long. 10° 25′.

FORMICOLA, a town of Naples, in Lavora; ſix miles E. of Capua.

FORMIGALES, a town of Spain, in the province of Aragon; 10 miles S.E. of Ainſa.

FORMIGI, a town of Italy, in the department of the Panaro; four miles S. of Modena.

FORMIGNANO, a town of the duchy of Urbino; ſeven miles from Foſſombrone.

FORMIGUE, a ſmall rocky iſland, near the French coaſt, in the Mediterranean. N. lat. 43° 8′. E. long. 6° 18′.—Alſo, a ſmall iſland in the Mediterranean, near the S. coaſt of the Morea. N. lat. 36° 46′. E. long. 21° 49′.

FORMING is uſed for the act of giving being or birth to any thing.

The word is alſo ſimply uſed for giving the figure to any thing. The potter forms his veſſels as he pleaſes. Geometry teaches how to form all kinds of figures.

It is alſo uſed for the producing of a thing: thus, the lineaments of the face began to be formed.

Forming *of a Siege*, in *Military Language*, is the making lines of circumvallation, to fortify the camp, and diſpoſing things for the attack of a place in form.

They alſo ſay, to form a ſquadron or battalion; meaning, to range the ſoldiers in form of a ſquadron, &c.

The term is alſo uſed in ſpeaking of a body of forces, which being out of any order of ſquadrons, battalions, &c. do halt, range themſelves in order, and put themſelves in a condition for the attack.

Forming the line, is drawing up infantry, cavalry, and artillery into line of battle. See Line.

Forming *the flank*, *Angle*. See Angle.

Forming, in *Grammar*, is uſed in ſpeaking of certain tenſes of verbs, which are made from others, by a change of certain letters.

The preſent tenſe is formed from the infinitive. Compound and derivative words alſo, and even all that have any etymology, are ſaid to be formed.

FORMOCHE, in *Geography*, a ſmall iſland in the Grecian Archipelago; nine miles N. of Patmos.

FORMOSA, or Tai-ouan, an iſland in the Chineſe ſea, ſeparated from the province of Fo-kien in China by a ſtrait, about 60 miles in its narroweſt part. This iſland, ſituated between 22° 8′, and 25° 20′ N. lat., and 120° to 122° E. long., is about 240 miles in length from north to ſouth, and about 60 miles in its greateſt breadth from eaſt to weſt, but much contracted at each extremity. Formoſa, though lying ſo near to the coaſt of China, was not known to the Chineſe until the year 1430. The Dutch formed an eſtabliſhment in the weſtern part of it in 1634, and built the fort of Zealand, by which they ſecured to themſelves the principal port of the iſland; but they were driven from thence in 1659, or 1661, by a Chineſe pirate, who made himſelf maſter of the whole weſtern part, which afterwards, *viz.* in 1682, ſubmitted to the authority of Kang-hi, emperor of China. This iſland is divided by a long chain of mountains, running from north to ſouth, into two parts, the eaſtern and weſtern. The former part is little known, but the latter is divided into three diſtinct governments, ſubordinate to the governor of Taï-ouan, the capital of the iſland, who is himſelf ſubject to the viceroy of the province of Fo-kien. This part, which is poſſeſſed by the Chineſe, preſents extenſive and fertile plains, watered by a great number of rivulets that fall from the eaſtern mountains. Its air is pure and wholeſome, and the ſoil produces, in abundance, corn, rice, and moſt other grains. Moſt of the Indian fruits are alſo found here; ſuch as oranges, bananas, pine-apples, guavas. papaws, and cocoa-nuts; and ſome of thoſe of Europe, particularly peaches, apricots, figs, raiſins, cheſnuts, pomegranates, water melons, &c. Tobacco, ſugar, pepper, camphor, and cinnamon are alſo common. Horſes, ſheep, and goats are very rare in this iſland; of hogs, which abound in China, here are few; domeſtic poultry, ſuch as fowls, geeſe, and ducks,

are very plentiful: pheaſants alſo are ſometimes ſeen, and monkies and ſtags have multiplied ſo much, that they wander through the country in large flocks. The inhabitants of Formoſa rear a great number of oxen, which they train for riding, from a deficiency of horſes and mules, and which they accuſtom to go as expeditiouſly as the beſt horſes, furniſhing them with a bridle, ſaddle, and crupper. The only important article that ſeems to be wanting in Formoſa is wholeſome water, that which it ſupplies being of a deleterious quality. In this iſland there are few mulberry trees, and conſequently little ſilk is produced: but if the Chineſe were permitted to form eſtabliſhments here, various profitable manufactures might be introduced. Thoſe who come hither muſt be protected by paſſports from the Chineſe mandarins, who grant them at a very dear rate, and accompany them with intolerable exactions and oppreſſions. The Chineſe connive at this conduct on the part of the mandarins, becauſe it ſerves to prevent numerous emigrations to this iſland, which is rendered a place of great importance by its proximity to China. Ever ſince Tartar conquerors have been on the throne, they are afraid leſt any revolt ſhould happen in Formoſa, and diſturb the ſecurity and tranquillity of the empire: and in order to prevent any diſturbance, the Tartars keep a garriſon here of 10,000 men, changing it every three years, or more frequently, if they find ſuch a meaſure to be neceſſary.

The capital of this iſland, called Taï-ouan, is large and populous, and a place of great trade. It furniſhes every neceſſary of life; not only the natural productions of the iſland, ſuch as rice, ſugar, tobacco, ſalt, ſtag's fleſh dried, fruits of all kinds, medicinal herbs, cotton cloth, hemp, and various ſorts of bark, but ſuch foreign commodities as are imported hither, ſuch as Chineſe and Indian cloths, ſilk ſtuffs, varniſh, porcelain, various kinds of European goods, &c. The ſtreets are for the moſt part ſtraight, and covered with awning during ſeven or eight months in the year, for the purpoſe of moderating the exceſſive heat of the ſun. Theſe ſtreets are 30 or 40 feet broad, and ſome of them about a league in length; almoſt all of them are bordered with houſes belonging to the merchants, or with ſhops, in which are diſplayed ſilk ſtuffs, porcelain, lacquer-ware, and other kinds of merchandize, arranged in great order, ſo as to appear like ſo many ornamented galleries. The houſes are generally conſtructed of clay and bamboo-reeds, and are thatched with ſtraw. This capital of the iſland has neither mills nor any kind of works; its harbour is good, and ſhelters veſſels from every wind; but the entrance of it becomes every day more difficult, on account of the accumulation of ſand. Beſides this capital, the Chineſe have two other cities, and ſome villages, in which they reſide by themſelves, as they do not permit the Indians, who are their ſubjects, to live among them; ſlaves and domeſtics excepted. Theſe Indians are united into 45 villages, 36 lying towards the north, and nine towards the ſouth. The northern villages are very populous, and the houſes are built after the Chineſe manner. The habitations of the ſouthern iſlanders are only heaps of huts, or cottages of earth, in which they have no kind of furniture; but the middle part is occupied by a ſort of hearth or chimney, elevated to the height of two feet, and conſtructed of earth, upon which they dreſs their victuals. Their ordinary food is rice, or other ſmall grain, and the game they take by courſing, or kill with their arms. Theſe iſlanders poſſeſs a wonderful degree of agility, and run with ſuch ſwiftneſs, that they can almoſt outſtrip the fleeteſt grey-hound. Their favourite arms are lances, which they dart to the diſtance of 60 or 80 feet, with the greateſt dexterity and preciſion. They uſe bows and arrows, and can kill a pheaſant on wing with as much certainty as an European ſportſman could do with a fuſee. As they have neither plates, diſhes, nor ſpoons, they uſe their fingers in feeding themſelves, and eat their fleſh half raw. Their beds are formed of freſh-gathered leaves. Their bodies are naked, excepting a piece of cloth, which hangs from their girdle to their knees. Thoſe among them who, according to the judgment of their chiefs, have excelled by agility in running, or by dexterity in the chace, obtain the privilege of marking on their ſkin, by a very painful operation, ſeveral fantaſtical figures of flowers, trees, and animals; all have the right of blackening their teeth, and of wearing ornaments of bracelets, and crowns made of ſhells and cryſtal. The iſlanders of the northern parts, where the climate is colder, clothe themſelves with the ſkins of ſtags, which they kill in hunting; on their heads they wear a cap in the form of a cylinder, made of palm-leaves, and ornamented with ſeveral crowns placed one above another, on the top of which they fix plumes compoſed of the feathers of a cock or a pheaſant. The marriage ceremonies of the Formoſans approach very nearly to the ſimple laws of nature; parents are ſcarcely ever conſulted, but young perſons ſettle their matrimonial union according to their own diſcretion.

Although theſe iſlanders are entirely ſubjected to the Chineſe, they ſtill preſerve ſome ſmall remains of their ancient government. Each village chooſes two or three old men of the greateſt reputation for probity; and in conſequence of this choice, they become the rulers or judges of the hamlet, and have the power of finally determining all differences: and if any one ſhould refuſe to abide by their judgment, he would be immediately baniſhed from the village, nor could any of the inhabitants afterwards dare to receive him.

The tribute impoſed by the Chineſe is paid in grain, and the mode of laying and collecting this impoſt is ſettled by a perſon ſpecially appointed for this purpoſe. But theſe perſons are very arbitrary and oppreſſive; inſomuch that they have by their tyranny cauſed the deſertion of three villages in the ſouthern part of the iſland, where were formerly twelve. They expelled the tax-gatherers, refuſed to pay tribute to the Chineſe, and joined themſelves to the independent nation in the eaſtern part of the iſland.

In 1782 a dreadful diſaſter befel Formoſa, occaſioned by a violent hurricane, which cauſed ſuch a ſwell of the ſea, that it overwhelmed a great part of the iſland, and deſtroyed many buildings on the land, with ſtores of various kinds contained in them, ſeveral ſhips and their cargoes in the harbour, a quantity of proviſions and growing crops. This grievous calamity, however, was redreſſed by the paternal attention and care of the Chineſe emperor.

Between Formoſa and the continent are ſeveral ſmall iſlands called "Pong-hou" by the Chineſe, and "Piſcadores" by the Europeans, which form a kind of Archipelago; of theſe iſlands, the principal only is inhabited by a Chineſe garriſon under the command of a mandarin. Duhalde. Groſiere.

Formosa, an iſland of the Atlantic, near the coaſt of Africa, about ſix miles long and one wide. The ſoil is fertile, and well covered with trees, but wants ſprings of good water. N. lat. 11° 29'. W. long. 14° 20'.

Formosa, *Benin*, or *Argon*, a river of Africa, which riſes in the interior part of Benin, and runs into the Atlantic. N. lat. 5° 40'. W. long. 4° 20'. For ſeveral leagues along the river upwards the land is low and marſhy, but the banks are adorned with lofty trees, and divided by branches of the river into a number of iſlands, which afford a pleaſant proſpect: however, the air is inſalubrious, and the muſquitoes innumerable.—Alſo, a river of Africa, which

runs

runs into the Indian ſea, S. lat. 34° 18'.—Alſo, a river of Brazil, which runs into the Atlantic, S. lat. 22° 25'.

Formosa *Bay*, a bay of the Indian ſea, on the coaſt of Africa. S. lat 2° 45'.

Formosa, *Cape*, a cape on the coaſt of Guinea, ſo called from its beautiful appearance; it is low, flat, and woody. N. lat. 5° 45'. E. long. 4° 52'.—Alſo, a cape on the coaſt of Malacca; 30 miles S.E. of Malacca.

FORMOSUS, Pope, in *Biography*, ſucceeded to the high dignity on the death of Stephen VI. He had poſſeſſed, previouſly to his election to the papal chair, high church honours, and had been biſhop of Porto, and ſent legate from the Roman ſee into Bulgaria, to ſolve ſome doubts relating to religious matters which were entertained by the people of that country, who had lately become converts to the Chriſtian faith. Under the pontificate of John VIII. he was accuſed of conſpiring againſt the lives of the emperor and pope, and not appearing to anſwer the heavy charge, he was excommuncicated and anathematized. To make his peace he was obliged to ſwear that he would never return to Rome, nor reſume the epiſcopal dignity, but content himſelf, during the remainder of his life, with lay communion. In 883 he was abſolved from his oaths by pope Marinus, who declared him innocent of the crimes alleged, and reſtored him to his epiſcopal functions: and in 891 he was elected pope in the room of Stephen. Formoſus was the firſt pope who was tranſlated from another ſee to that of Rome; for, till his time the biſhops of Rome had all been raiſed to that office from among the preſbyters and deacons of the church. Formoſus was ſcarcely ſettled in his chair when legates arrived at Rome from Conſtantinople to ſettle the diſpute reſpecting the perſons who had been ordained by the patriarch Photius, who had been anathematized by the preceding popes. Being unable to accompliſh the object of their miſſion, they returned, and the conference which was intended to heal ſubſiſting diviſions, widened ſtill farther the breach between the eaſtern and weſtern churches. Formoſus, in the following year, ſent legates to preſide at the council of Vienna, to redreſs abuſes that prevailed in the kingdom of Arles: he eſpouſed the cauſe of Charles the "Simple" of France againſt Odo, who, upon the death of that prince's father, had ſeized on the kingdom of Aquitaine, and had even been crowned king of France. His letters, however, to Odo were unavailing, and it was not till his death that the family of Charlemagne regained poſſeſſion of the whole of France. In the year 894 Formoſus crowned Lambert emperor in the room of his deceaſed father Wido: but Berengarius laid claim to the kingdom of Italy, which cauſed a bloody war between the contending parties. The pope invited Arnulph, king of Germany, to Rome, promiſing to crown him emperor, provided he reſtored peace to the country by vanquiſhing the preſent emperor and his rival. Arnulph complied, entered Italy with a powerful army, made himſelf maſter of Lombardy, marched to Rome, obtained poſſeſſion of the city, and was crowned emperor by the pope. After this, to ſettle matters more completely, the kingdom of Lombardy was divided between Lambert and Berengarius, and Arnulph returned to Germany. Formoſus died in the year 896, after a reign of about four years and a half. In the "Collectio Conciliorum" there are two letters extant which bear the name of Formoſus, one reſpecting the affairs of the Eaſt, and the other addreſſed to the biſhops of England; the latter is not generally regarded as genuine. The ſucceſſor of Formoſus, Stephen VII., was his bitter enemy, and determined to diſgrace him after his death, whom he durſt not openly oppoſe while alive. He accordingly, as one of his firſt acts, ſummoned a council to meet at Rome, and placed the body of the dead pontiff, taken from his tomb, on the pontifical throne; and having aſſigned him a deacon to plead his cauſe, he uttered a furious philippic againſt him, and pronounced him guilty of the charge of illegally intruding himſelf into the apoſtolic ſee. He was next ſtripped of his ornaments; three of the fingers, with which it was cuſtomary to beſtow the papal benediction, were cut off, and the body, with a large ſtone ſuſpended about its neck, was thrown into the Tyber, and all ordinations which Formoſus had conferred were declared invalid. In the next pontificate, under Theodore II. the body of Formoſus was reſtored with great pomp to its ſepulchre in the Vatican; and by John IX. the acts of Stephen's council were condemned to the flames. See John, Stephen, and Theodore.

FORMULA, a rule, or model, or certain terms preſcribed and decreed by authority, for the form and manner of an act, inſtrument, proceeding, or the like. The Roman law was full of formulas. The formulas of Marculphus, with M. Bignon's Comment, are in great eſteem.

Formula, in *Church Hiſtory* and *Theology*, denotes a formulary or profeſſion of faith.

Formula, in *Mathematics*, a general expreſſion for reſolving certain caſes or problems. E. G. $\sqrt{dx - x^2}$ is the formula that expreſſes the ordinate of a circle, having d for its diameter and x for its, abſciſſa.

Formula, in *Medicine*, denotes a little form or preſcription, ſuch as phyſicians direct in extemporaneous practice, in diſtinction from the greater forms, which are the officinal medicines. See Prescription.

FORMULARY, a writing, containing the form or formula of an oath, declaration, atteſtation, or abjuration, &c. to be made on certain occaſions. There are alſo formularies of devotion, of prayers, &c. Liturgies are formularies of the public ſervice in moſt churches.

FORNA, in *Ichthyology*, a name given by Hildegard, and others, to the trout.

FORNACALIA, or Fornicalia, in *Antiquity*, a feaſt held among the ancient Romans, in honour of the goddeſs Fornax, or Fornix. It was ſolemnized with ſacrifices, performed before the mouth of an oven, wherein they dried their corn, baked their bread, &c. The fornacalia were moveable: the grand curio proclaimed the time of celebration every year on the twelfth of the calends of March. They were firſt inſtituted by Numa; and the quirinalia were inſtituted for the ſake of ſuch as had not kept the fornacalia.

FORNAGE, Fornagium, in our *Old Writers*, ſignifies the fee taken by a lord from his tenants, bound to bake in the lord's oven, or for a permiſſion to uſe their own; this was uſual in the northern parts of England. Plac. Parl. 18 Ed. I. See Assisa *panis et cereviſiæ*. (51 Hen. III.)

The word comes from the French *fournage*, which ſignifies the ſame.

FORNAZZANO, in *Geography*, a town of Italy, in the departmen of the Amona; 15 miles S.S.W of Faenza.

FORNELLA, a port and bay in the iſland of Minorca. The port is ſituated about ſix miles from mount Toro, and deſcribes a circle, the entrance of which is very narrow and facing the north. The bay is capable of containing the largeſt fleet, and perfectly ſheltered. The port is defended at the entrance by a ſmall ſquare fort, conſtructed of hewn ſtone, with baſtions and foſſes. This rampart is covered with magazines and lodgments, which are vaulted; on the oppoſite ſide is a tower, and at the further end of the port, upon a rock or iſle, is a fort, built of wood. The eſtabliſhment is capable of ſupporting a conſtant garriſon

riſon of 300 men. Near this is a ſmall village of the ſame name, inhabited only by fiſhermen.

FORNELLO, a town of Naples, in the Moliſe; 17 miles W. of Moliſe.—Alſo, a river which runs through the city of Naples into the ſea.

FORNICATION, Whoredom, the act or crime of incontinency between ſingle perſons; for, if either of the parties be married, it becomes adultery. The term is derived from the *fornices* in Rome, where lewd women proſtituted themſelves for money.

By the ancient law of England, the firſt offence herein was puniſhed with three months impriſonment: the ſecond was made felony by an act paſſed A.D. 1650, in the time of the uſurpation. The ſpiritual court hath cognizance of this offence; and doing public penance is the chief puniſhment. But by ſtat 27 Geo. III. c. 44 the ſuit muſt be inſtituted within eight months, and not at all after the intermarriage of the offending parties. Formerly courts-leet had power to inquire of and puniſh fornication and adultery: in which courts the king had a fine aſſeſſed on the offenders, as appears by the book of Domeſday. 2 Inſt. 488. See Bastard.

Fornication is ſometimes uſed as a generical term, including all kinds of offences againſt chaſtity.

Its ſpecies are, 1. *Simple fornication*, which is that committed with a proſtitute. 2. *Stuprum*, that committed with perſons of reputation and ſobriety. 3. That committed with relations, called *inceſt*. 4. That committed with married perſons, *adultery*. 5. That committed with perſons conſecrated to God, *ſacrilege*. 6. That committed between perſons of the ſame ſex, *ſodomy*. 7. That committed by perſons on themſelves, *manuſtupration*. And, 8. That committed with beaſts, *beſtiality*.

FORNIX, in *Anatomy*, a medullary body contained in the lateral ventricles of the brain. See Brain.

FORNULUS, in *Geography*, a town of Italy, in Venetia, N. E. of Aquileia.

FOROMAN, a town of the iſland of Sumatra, near the weſt coaſt; 150 miles S. of Acheen.

FORONOVO, a town of Italy, in the duchy of Parma; 8 miles W. S. W. of Parma.

FORPRISE, in *Law*, an exception, or reſervation; in which ſenſe the word is uſed in the ſtatute of Exon. 14 Edw. I.

We ſtill uſe it in conveyances and leaſes, wherein excepted and forpriſed are ſynonymous terms.

Forprise is alſo uſed for an exaction; in which ſenſe it amounts to the ſame with forecapium.

"Totum pratum, &c. ſine quacunque forpriſa in excambium pro placca dedit."

FORQUERAG, Anthony, and John Baptist Anthony, in *Biography*, father and ſon, both French muſicians, who were patronized by Louis XIV. during their infancy. Anthony, the eldeſt, was born at Paris in 1671; his father, a profeſſor on the violin, gave him leſſons in early infancy, of which he profited ſo much, that at five years old he played many times to the king, who uſed to call him his "petit prodige." At 20, the young Forquerag was the beſt performer on the violin of his time; he had alſo a genius for compoſition, and produced pieces equally harmonious and melodious. His talents, and ſtill more the ſweetneſs of his temper, introduced him into the beſt company, which he regaled with his performance whenever deſired. The regent duke of Orleans choſe him for his maſter in muſic, and conſtantly honoured him with his patronage. This muſician died at Mantes in 1745, and left a ſon born in 1700. This was John Baptiſt Anthony, of the king's chamber and chapel band, who equalled his father in talents. He, as well as his father, performed before Louis XIV. at the age of five or ſix, and aſtoniſhed the whole court by the prodigious execution which he had acquired at ſo tender an age. The prince of Conti had a great affection for this muſician, and engaged him in his ſervice. On the death of that prince, Forquerag quitted the profeſſion, and finiſhed his days in tranquillity in the boſom of his family, by whom he was much beloved and reſpected. Madam Forquerag, his wife, excelled on the harpſichord, and till 1780 played with ſo much grace and facility, that ſhe may be regarded at the head of female dilettanti. Laborde.

FORRAGE, or Forage, proviſion for cattle, of hay, oats, and ſtraw; particularly in war.

Skinner derives the word from *foras agere*, by reaſon they go abroad to ſeek forrage; others from *far*, which anciently ſignified any kind of corn or grain. Menage, from *foderagium*, of *foderum*, or *fodrum*, which the Romans uſed in the ſame ſenſe. Cujas and Du-Cange derive it from the German *futter*, horſe meat; Voſſius, from the German *foden*, or *voeden*, to feed; Nicod, from *farrago*, which literally ſignifies what we call forrage, and figuratively, a mixture of divers kinds of things; Hicks derives it from the Saxon *fodra*, or the Engliſh *fodder*, or the baſe Latin *fodrum*. See Fodder.

This term relates to the acquiſition and diſtribution of ſuch ſupplies as are immediately neceſſary for the ſubſiſtance of troops, or for the formation or maintenance of any poſt or ſtation; being for the moſt part an arbitrary demand, ſuch as we underſtand by the affectedly delicate term "requiſition" uſed by the French, but which is in effect only a contributory ſpecies of pillage: it is to be ſuppoſed that foraging takes place chiefly in an enemy's country. Such is, indeed, the caſe; whence it is found expedient to ſtrengthen the covering parties ſent out with foragers, ſo far as may be ſafely done without weakening the main body, or creating too much fatigue.

The cavalry form a very prominent feature on all forages; each trooper being furniſhed with a ſack, ſuch as may lie conveniently over the ſaddle-bows, and another over the loins of his ſteed, on the cloak-pad, or eventually to ſtand upright on it, and to faſten by means of a ſtrap paſſing round his own waiſt. Whatever means may be employed it is highly neceſſary that no faſtenings ſhould be uſed, except ſuch as may be undone in an inſtant: nor ought any horſe to be laden ſo as to prevent his keeping up a moderate trot on emergency. Further attention ſhould be paid to keeping every trooper's arms clean for action.

When troops are detached on this important duty, the whole of the country muſt be well ſearched, leſt the enemy, having intelligence of the intention, ſhould take means, by ambuſcade or otherwiſe, for cutting off the foragers. For this purpoſe ſmall parties of cavalry, each having a trumpeter, ſhould proceed beyond the places to be foraged, and poſt lines of *videttes*, or centries, ſo as to obtain a full command of the whole country; they being ſituate on ſuch eminences, ſteeples, &c. as might beſt favour the precaution. In the mean while the ſeveral foragers collect the ſeveral articles they may find, or ſtand in need of; taking care to pack them into the ſmalleſt compaſs, and ſecuring every bundle with proper bands, &c.

So ſoon as an alarm is given, the troops muſt concentrate, in ſuch manner as may have been previouſly directed, but without loſing ſight of the object of their miſſion. Here ariſes a very delicate and critical caſe; for, on the judgment of the ſuperior officers all will depend. If a large

force ſhould appear, ſuch as could not ſafely be oppoſed, the forage muſt be abandoned; unleſs, indeed, reinforcements may be obtainable within a reaſonable time; ſuch being the caſe, the moſt obſtinate defence muſt be made; eſpecially if the army be in diſtreſs for proviſions, &c.

The enemy, though unable perhaps to make any efficient attack, will endeavour to excite alarm among foragers, ſo as either to cauſe their remaining within narrow limits, or to retire with a ſcanty ſupply. Such ſhould always be diſtinguiſhed, and though vigilantly watched, leſt a larger body ſhould be at hand, ought never to prevent the completion of the duty. When the whole are ready for retreat, the carts, waggons, &c. if any are employed, are firſt ſent on towards the camp, together with the infantry as an eſcort; the laden cavalry then cloſe in, and, in their turn, are protected by the eſcorts of horſe.

Where great reſiſtance is expected, it is ſometimes neceſſary for a few guns, eſpecially horſe-artillery, to proceed with the foragers; but the utmoſt endeavours ſhould be uſed to avoid coming to action. In ſome inſtances the whole army move to the ſcene of plunder, for the purpoſe of carrying off whatever may be procurable, and for which conveyance can be provided; the camp being left under charge of a few ſmall detachments, or piquets; but ſuch can happen only on great emergency, or when the enemy are ſo near as to render it inexpedient to detach any portion.

A ration of forage, for the daily conſumption of one horſe, conſiſts of 10lb. of oats, 20lb. of hay, and 5lb. of ſtraw. When hay may not be obtainable more oats are allowed, or *vice verſâ*. When on foreign ſervice ſubſtitutes are of courſe adopted, and diſtributed *ad valorem*.

FORRAGE-*guard*, in *Military Affairs*, a detachment ſent out to ſecure the foragers. The forrage-guard is poſted at all places, where the enemy's parties may come to diſturb the foragers. This guard is likewiſe called the *covering party*, and marches generally that night before the foraging, that they may be poſted in the morning before the foragers come. The guard conſiſts both of horſe and foot, and muſt ſtay at their poſt till the foragers be all come off the ground. See the preceding article.

FORRENBACH, in *Geography*, a town of Germany, in the territory of Nuremberg; five miles E. S. E. of Herſbach.

FORRES, a town ſituated near the mouth of the river Findhorn, on a riſing ground three miles diſtant from the bay of the ſame name, is a royal burgh, in the county of Moray; and though it is uncertain when it received this privileged diſtinction, yet it is noticed in records as a conſiderable place in the thirteenth century. The corporation conſiſts of a provoſt, two bailiffs, and a dean of guild, elected annually; and the town, conjointly with Fortroſe, Nairn, and Inverneſs, ſends one member to the Britiſh parliament: it is the ſeat of a preſbytery. The houſes, which are in general neatly built, amounted, according to the returns made to government in 1801, to 663, containing 3114 inhabitants; of whom 380 were employed in trade and manufactures. The river is navigable up to the village of Killos, within two miles of the town, where is the port belonging to this place. The Findhorn abounds with ſalmon and other fiſh, and the fiſheries on it are very productive. To the ſouth of the town, on an eminence, ſtands the houſe of Burdsyards, commanding a fine proſpect, and ſurrounded by extenſive plantations; on an eminence at the weſt end of the town ſtood a caſtle, built by ſome of the early kings, and burnt at the reformation. Near Forres, in the pariſh of Rafford, is a very ſingular remain of antiquity; it is an upright pillar, known under the denomination of "Sweno's ſtone." This, which exceeds all other obeliſks to be ſeen in Scotland, is perhaps the fineſt monument of the Gothic kind to be found in Europe. It is thus deſcribed by Mr. Pennant in his Tour in Scotland. "It is three feet ten inches broad, and one foot three inches thick; the height above ground is 23 feet; below, as it is ſaid, 12 or 15. On one ſide are numbers of rude figures of animals and armed men, with colours flying; ſome of them ſeem bound like captives. On the oppoſite ſide was a croſs included in a circle, and raiſed above the ſurface of the ſtone. At the foot of the croſs are two gigantic figures, and on one of the ſides is ſome elegant fret-work." The column appearing likely to fall, a few years ſince was ſet upright, and guarded by the addition of ſeveral free-ſtone ſteps erected round the baſe. Various have been the conjectures reſpecting the age and purport of this monument. That of the late reverend Mr. Cordiner appears the moſt probable. In his remarks, which accompanied a drawing of the pillar ſent to Mr. Pennant, he ſuppoſes it to have been ſet up in commemoration of the peace concluded between Malcolm, king of Scotland, and Canute, the Daniſh king of England, in the year 1002; when the Danes, who had long been in poſſeſſion of Moray, finally relinquiſhed that province by ſtipulation.

In a moor not far from Forres, Shakſpeare places Macbeth's rencounter with the witches. Below the ſtone, at the head of an inlet of the ſea, are ſome remains of Kinloſs abbey, founded in 1150 by David I. for Ciſtercian monks, and amply endowed. The ruins were ſold, in 1651, to build the citadel of Inverneſs. On the oppoſite ſide of that inlet was Conebin eſtate, overwhelmed with ſand about a century ago. The country, for ſeveral miles weſt of Forres, is level, well cultivated, and adorned with fine plantations, ſeats, old caſtles, &c. In a hollow of that tract there was diſcovered, in the laſt century, a ſhip's anchor four feet below ground, whence, and from other circumſtances, it would appear that the whole of the low-lands along the coaſt of the Frith was anciently covered with the ſea. To the ſouth of Forres lies the foreſt and caſtle of Tarnaway, formerly the reſidence of the earls of Moray. This caſtle is noted for its ſpacious hall, named from earl Randolph, one of the ſupporters of Robert Bruce. In the church-yard of Dyke, weſt of Forres, is part of a ſtone-croſs ornamented with rude reliefs. N. lat. 57° 36'. W. long. 3° 42'.

FORRESTER'S ISLAND, a ſmall iſland in the North Pacific ocean, about 14 miles N. W. from the S. W. coaſt of the Prince of Wales's Archipelago, ſo called by Mr. Dixon. N. lat. 54° 50'. E. long. 126° 38'.

FORS, a town of Sweden, in Weſt Gothland; 17 miles S. S. E. of Uddevalla.—Alſo, a town of Sweden, in Jamtland; 44 miles N. of Sundſwall.

FORSE, a river of Scotland, in Caithneſs; which runs into the North ſea; ſix miles W. of Thurſo.

FORSES, CATADUPÆ, a term uſed in Weſtmoreland for water-falls.

FORSKALEA, in *Botany*, named by Linnæus in memory of his pupil Peter Forſkal, a Swede, who being ſent, at the expence of the king of Denmark, to inveſtigate the natural productions of the Eaſt, in company with the celebrated Niebuhr, died at Jerim in Arabia, July 11, 1763, aged 31. His notes and deſcriptions, rich in information reſpecting the natural hiſtory of Egypt and Arabia, but not corrected by references to other authors, as they would have been by himſelf for the preſs, were publiſhed in three quarto volumes, under the direction of his fellow-traveller, at Copenhagen in 1775. Linn. Mant. 11. Schreb. Gen. 268. Willd. Sp. Pl. v. 2. 474. Mart. Mill. Dict.

v. 2. Ait. Hort. Kew. v. 2. 121. Juſſ. 403. Gærtn. t. 68. (Caidbeja; Forſk. Fl. Ægyptiaco-Arab. 82.) Claſs and order, *Octandria Tetragynia*. Nat. Ord. *Scabridæ*, Linn. *Urticæ*, Juſſ.

Gen. Ch. *Cal.* Perianth erect, of four oblong, parallel, permanent leaves. *Cor.* Petals eight, rude, ſpatulate, concave, erect, withering, ſhorter than the calyx, the claw and border of equal length. *Stam.* Filaments eight, thread-ſhaped, one within each petal, elaſtic, the length of the calyx; anthers of two roundiſh lobes. *Piſt.* Germens four, diſtant, oblong, woolly; ſtyles briſtle-ſhaped; ſtigmas ſimple. *Peric.* none. *Seeds* four, oblong, compreſſed, tapering at each end, enveloped in wool.

Eſſ. Ch. Calyx of four leaves, longer than the corolla. Petals eight, ſpatulate. Pericarp none. Seeds four, entangled in wool.

Obſ. Linnæus remarked that "the number in the parts of fructification varies, and that the flower is extremely difficult to diſſect and underſtand;" owing to the wool with which all its organs are entangled. He places this genus in *Decandria Pentagynia*. Murray, Schreber, and Willdenow have conſidered it as belonging to *Octandria Tetragynia*. Juſſieu, not without heſitation, but apparently for good reaſons, differs widely from Linnæus and his followers in his view of this flower, conſidering it as monoecious, and underſtanding the petals of Linnæus as monandrous male florets, each of one ſcale, varying in number from ſeven to ten, and ſurrounding the female florets, which are central, and vary likewiſe in number from three to five, the wool being to them in the place of the ſcales of the others. To this it may be objected, that the number of the female organs always keeps pace in *Forſkalea* with the male ones, as in true ſimple flowers, whereas in monoecious, or compound ones, a luxuriance in the one kind is generally, perhaps invariably, compenſated by a deficiency in the other. The analogy of *Parietaria* moreover, a genus cloſely allied to *Forſkalea*, is not favourable to the theory of Juſſieu. We however readily follow this author and Niebuhr in preference to Linnæus and others, in the orthography of the name, and conſequently *Salvia Forſkalii* is the true ſpelling, not *Forſkælii*. Three ſpecies of this genus are known.

1. F. *tenaciſſima*. Linn. Mant. 72. Suppl. 245. Linn. fil. Ic. t. 1. Jacq. Hort. Vindob. v. 1. t. 48. (Caidbeja adhærens; Forſk. Fl. 82. Chamædryfolia tomentoſa Maſcatenſis; Pluk. Almageſt. 97. Phyt. t. 275. f. 6. Luſſaq of the Arabs.)—"Plant clothed with briſtly hairs. Leaves elliptical, pointleſs. Calyx-leaves oblong-lanceolate, acute." Ait. H. Kew.—Native of vallies between the calcareous hills of the deſert to the eaſt of Cairo. This plant has much of the aſpect of the common Pellitory, *Parietaria officinalis*, except a more hoary whiteneſs on the backs of the leaves and about the calyx. It is annual, flowering in the latter part of ſummer, and requires to be kept with us in the green-houſe, where few perſons, except for curioſity, would deſire to have it. The briſtles of the *ſtem* and *leaves* are finely hooked, by which they ſtick to any thing that comes in their way. The *calyx* is enlarged after flowering, and falls off with the ſeed.

2. F. *candida*. Linn. Suppl. 245. Thunb. Prod. Cap. 77. (F. ſcabra; Retz. Obſ. faſc. 3. 31.)—Plant rough with cartilaginous points. Leaves elliptical, wavy, pointleſs. Calyx-leaves obovate, obtuſe—Native of the Cape of Good Hope, from whence, as we learn by the Hortus Kewenſis, it was ſent by Mr. Maſſon to Kew in 1774, where it is kept in the green-houſe, and flowers in June and July. The *ſtem* is perennial and ſomewhat ſhrubby, much branched, rough, like the upper ſide of the *leaves*, with harſh horny points, often hooked. The blunt *calyx-leaves* moreover diſtinguiſh this ſpecies from the preceding.

3. F. *anguſtifolia*. Retz. Obſ. faſc. 3. 31. Murray in Comm. Gott. for 1784. 24. t. 2.—Plant briſtly. Leaves lanceolate, green on both ſides; their teeth briſtly. Calyx-leaves lanceolate, briſtle-pointed. Found by Maſſon in the iſland of Teneriffe. Hort. Kew.—It is annual, kept in the green-houſe, and flowers in July and Auguſt. This is like the other two, but rather more briſtly and with narrower *leaves*, which are ſcarcely hoary at the back, except when young. Their teeth are tipped with ſtraight ſpinous briſtles; their upper ſurface rough with hooked ones. The leaves of the *calyx* are remarkably narrow, and very briſtly. The *petals* are reddiſh.

Linnæus is ſuppoſed in the name of the firſt ſpecies, *tenaciſſima*, to have complimented rather than ſatirized the character of Forſkal, who was an indefatigable and acute obſerver, and did not eaſily forget what he had once acquired. In that of the ſecond, *candida*, one of the laſt names Linnæus ever applied, he unqueſtionably deſigned to do honour to the temper of his friend, whoſe works had juſt been preſented to him, from the king of Denmark, in a ſplendid form, and are now in the hands of the writer of this paragraph.

FORSOOTH, in *Antiquity*, a title of honour, anciently given to ladies, and ſtill retained, as well as dame, in ſome of the exiſting religious communities of Engliſh women, which were eſtabliſhed on the continent above two centuries ago, as forſooth Mary, forſooth Ann, no leſs than dame Mary, dame Ann, &c.

FORST, in *Geography*, a town of Germany, in the principality of Culmbach; 4 miles N. N. E. of Neuſtadt.

FORSTA, a town of Luſatia, on the river Neiſſe; the inhabitants of which are employed in manufacturing fine woollen and linen cloths and carpets, and brewing beer: 54 miles N. N. E. of Dreſden. N. lat. 51° 43'. E. long. 14° 40'.

FORSTENOVE, a town of Germany, in the biſhopric of Oſnabruck; 15 miles from Oſnabruck.

FORSTER, John, in *Biography*, a learned German divine, was born at Augſburg in the year 1495. He received the early parts of his education in his native city; and then went to Ingoldſtadt in Bavaria, where he enjoyed the opportunity of profiting by the inſtructions of the celebrated Reuchlin, who, though at that time in his ſeventieth year, took great delight in aſſiſting and encouraging the literary purſuits of young perſons. Under this tutor Mr. Forſter made great progreſs in his ſtudies, and excelled particularly in the Hebrew and Greek languages. From Ingoldſtadt he went to Leipſic, where he ſtudied theology, and thoſe other branches of literature which were connected with the clerical profeſſion. Here he firſt commenced teacher of the Hebrew language and divinity: he afterwards removed to the univerſity of Wittemberg, where he was admitted to the honour of doctor of divinity. At this univerſity he diſcharged, with high reputation, the duties of public profeſſor of Hebrew, and at the ſame time rendered eſſential ſervice to the Proteſtant religion by his labours as a preacher. When Luther undertook his tranſlation of the bible, he frequently availed himſelf of the aid of Forſter, and ſubmitted to his judgment reſpecting the ſenſe of difficult paſſages more readily than to that of any other man. He died at Wittemberg in 1556, when he was about ſixty-one years old, highly beloved for his candour and amiable diſpoſition, and reſpected for his great literary attainments. He was author of a valuable Hebrew

dictionary, which was printed at Basil in 1557. There were two other persons by the same name: the one a Lutheran divine, professor at Wittemberg, and minister at Eisleben, where he died in 1613. He was author of commentaries on Exodus, Isaiah, and Jeremiah, in three vols. 4to. a treatise "De interpretatione Scripturarum," 4to. and other critical and theological productions. The other, John Forster, entitled to notice, was a jurist at Padua, and author of a work entitled "Processus judiciarius Cameralis." Moreri. Gen. Biog.

Forster, Nathaniel, a learned divine of the church of England, was born at Stadscombe, Devonshire, in the year 1717. Soon after his birth his father, who was a clergyman, removed to Plymouth, where he educated his son in the elements of learning, and then sent him to the grammar-school of that town, of which he was the head scholar before he was thirteen years of age. In 1731 he was removed to Eton, and at the same time entered at Pembroke college, Oxford, in order to entitle him to the benefit of an exhibition of forty pounds per annum. In 1733 he was admitted scholar of Corpus Christi college, and after taking his degrees, he was elected fellow in the year 1739: in the same year he received deacon's orders, and in 1741-2 was ordained a priest. His time was chiefly spent at college in a close application to his studies, by which he acquired a high reputation, and a vast knowledge of the dead languages. His first preferment in the church was the rectory of Heathe, in Oxfordshire, which was presented to him in 1749 by the lord-chancellor Hardwicke, on the recommendation of Dr. Secker, bishop of Oxford, his earliest friend, who also introduced him to the notice of Dr. Butler, at that time bishop of Bristol, who appointed him his domestic chaplain, when he was translated to the see of Durham in 1750. Mr. Forster now quitted the university, and was admitted to the degree of doctor of divinity. He continued chaplain to the bishop of Durham till the death of that prelate, who, though he had not given him any preferment in the church, must have highly esteemed him, as he appointed him executor to his will, with a legacy of 200*l*. Dr. Forster now returned to college, with a determination to devote his time to literary pursuits; but in 1752 he was made one of archbishop Herring's chaplains, who in a short time promoted him to a prebendal stall in the church of Bristol, and presented him also with the valuable vicarage of Rochdale in Lancashire. He was elected a fellow of the Royal Society in 1755: made one of his majesty's chaplains, and appointed preacher at the Rolls chapel. In 1757 he married a lady of considerable fortune, and settled in Craig's court, Westminster; but before the end of the same year he died. Among his connections and friends he could rank almost all the eminent men of his time, and he left behind him a high character for all the private virtues that adorn life. He was author of many works, of which the principal are "Reflections on the natural antiquity of Government, Arts, and Sciences in Egypt," 1743. "Platonis Dialogi quinque: recensuit, notis illustravit, Nathaniel Forster, A M." &c. 1745. "Appendix Liviana, continens I. selectus Codicum. MSS. et editionum antiquarum lectiones, præcipuas variorum emendationes, et supplementa lacunarum in iis T. Livii que supersunt libris. II. J. Frienshemii supplementorum libros X. in locum decadis secundæ Livianæ deperditæ," 1746. "Biblia Hebraica, sine punctis, accurante Nath. Forster, &c. 1750." Gen. Biog.

Forster, John Reinhold, an eminent naturalist and philologist, was the son of a burgomaster at Dirschaw, in Polish Prussia, where he was born October the 22d, in the year 1729. In early youth he had few advantages for education; but about the age of fifteen years, he was admitted into the gymnasium of Joachimsthal at Berlin. Under the tuition of Menzelius and Heinsius, he made considerable progress in the learned languages: and he also devoted a part of his attention to the study of the Coptic, and to the acquisition of several of the modern languages, and particularly the Polish. In the year 1748, he was entered at the university of Halle, where he studied theology, and continued his application to the learned languages, among which he comprehended the oriental. After three years he removed to Dantzic, and distinguished himself as a preacher, imitating the French rather than the Dutch manner; and in 1753, he obtained a settlement at Nassenhuben. In the following year he married his cousin, Elizabeth Nikolai. During his residence in this place, he employed his leisure hours in the study of philosophy, geography, and the mathematics, without desisting from farther improvement in his acquaintance with the ancient and modern languages. With a small income and increasing family, the difficulties he experienced induced him to accept the proposal of removing to Russia, in order to superintend the new colonies at Saratow. Much, however, as he was approved during an interview with the members of government at Petersburgh, some circumstances occurred which rendered his new appointment of short duration; but on his return to the capital, advantageous offers were made to him both by the academy of sciences, and by that of Moscow, both which he thought proper to decline. Having for some time indulged unavailing expectations from the Russian government, he removed to London in the year 1766, with strong recommendations, but with very little money. After his arrival, he received from the government of Russia a present of 100 guineas; and he also made an addition to his stock by the translation of Kalm's Travels and Osbeck's Voyage. At this time lord Baltimore proposed to him a settlement in America, as superintendant of his extensive property in that country; but he preferred the place of teacher of the French, German, and natural history in the dissenting academy at Warrington. This situation, however, he soon abandoned; and returning to London, he was engaged, in the year 1772, to accompany captain Cook, as a naturalist, in his second voyage round the world. At this time he was 43 years of age, and his son George, who went with him, was 17. Upon his return to England in 1775, the university of Oxford conferred upon him the degree of doctor of laws. At this time he was projecting, with the assistance of his son, a botanical work in Latin, containing the characters of many new genera of plants, which they had discovered in the course of their voyage. An account of the voyage having been published by his son in English and German, the father was supposed to have had a considerable share in it; and as he had entered into an engagement not to publish any thing separately from the authorized narrative, he thus incurred the displeasure of government, and gave offence to his friends. Independently of the violation of his engagement, he was also chargeable with having introduced into his work several reflections on the government which appointed, and also on the navigators who conducted the expedition. The father and son, finding that, in consequence of these circumstances, their situation in London was become unpleasant, determined to quit England. Before the execution of their purpose, their condition became embarrassed and distressing; but happily for Mr. Forster, he was invited, in 1780, to be professor of natural history at Halle; he was also appointed inspector of the botanical garden;

and

and in the following year, he obtained the degree of M.D. His health, however, began to decline; and the death of his ſon George ſo deeply impreſſed his mind as to aggravate his other complaints. Towards the commencement of the year 1798, his caſe became deſperate; and before the cloſe of this year, *viz.* on the 9th of December, his life terminated at the age of 69 years and ſome months. Mr. Forſter's diſpoſition was, unfortunately for his happineſs and reputation, extremely irritable and litigious; and his want of prudence involved him in perpetual difficulties. The following character given of him by the celebrated Kurt Sprengel of Halle, is delineated by the partiality of a friend: "To a knowledge of books in all branches of ſcience, ſeldom to be met with, he joined an uncommon fund of practical obſervations, of which he well knew how to avail himſelf. In natural hiſtory, in geography, both phyſical and moral, and in univerſal hiſtory, he was acquainted with a vaſt number of facts, of which he who draws his information from works only has not even a diſtant idea. This aſſertion is proved in the moſt ſtriking manner by his "Obſervations made in a Voyage round the World." Of this book it may be ſaid, that no traveller ever gathered ſo rich a treaſure on his tour. What perſon of any education can read and ſtudy this work, which is unparalleled in its kind, without diſcovering in it that ſpecies of inſtructive and pleaſing information which moſt intereſts man, as ſuch? The uncommon pains which Forſter took in his literary compoſitions, and his conſcientious accuracy in hiſtorical diſquiſitions, are beſt evinced by his "Hiſtory of Voyages and Diſcoveries in the North," and likewiſe by his excellent archeological diſſertation "On the Byſſus of the Ancients." Reſearches ſuch as theſe were his favourite employment, in which he was greatly aſſiſted by his intimate acquaintance with the claſſics. Forſter had a predilection for the ſublime in natural hiſtory, and aimed at general views rather than detail. His favourite author, therefore, was Buffon, whom he uſed to recommend as a pattern of ſtyle, eſpecially in his Epoques de la Nature, his deſcription of the horſe, camel, &c. He had enjoyed the friendſhip of that diſtinguiſhed naturaliſt; and he likewiſe kept up an uninterrupted epiſtolary intercourſe with Linnæus, till the death of the latter. Without being a ſtickler for the forms and ceremonies of any particular perſuaſion, he adored the eternal Author of all which exiſts in the great temple of nature, and venerated his wiſdom and goodneſs with an ardour and a heart-felt conviction, that, in my opinion, alone conſtitute the criterion of true religion. He held in utter contempt all thoſe, who, to gratify their paſſions or imitate the prevailing faſhion, made a jeſt of the moſt ſacred and reſpectable feelings of mankind. His moral feelings were equally animated: he was attracted with irreſiſtible force by whatever was true, good, or excellent. Great characters inſpired him with an eſteem, which he ſometimes expreſſed with incredible ardour."

His other works, beſides thoſe above mentioned, are chiefly compilations and tranſlations. He alſo communicated ſeveral papers to the Royal Society, the Academy of Sciences at Stockholm, the Imperial Academy of Sciences at Peterſburgh, and other learned ſocieties; which appear in their reſpective Tranſactions and Memoirs. Gen. Biog.

Forster, George, ſon of the preceding, was born at Dantzic in 1754, and accompanied his father to England, when he was about 12 years of age. At Warrington, where he ſtudied for ſome time, he acquired a perfect uſe of the Engliſh tongue; and poſſeſſing a retentive memory and fertile imagination, he diſtinguiſhed himſelf by his various literary and ſcientific attainments. We have already mentioned that he accompanied his father in the circumnavigation of the globe; and on leaving England, after their return, he wiſhed to ſettle at Paris. After a temporary reſidence in that city, he removed, in the year 1779, to Caſſel, and undertook the office of profeſſor of natural hiſtory in the univerſity of that place. He afterwards accepted the offer of a chair in the univerſity of Wilna; but found no permanent ſatisfaction in a country where liberty was expiring under the intrigues of Ruſſia and Pruſſia. Deſirous of a retreat, he entered into a treaty with Catherine II., who projected a voyage of diſcovery round the world; but the propoſed expedition was prevented by a war with the Ottoman Porte; and thus the hopes of Forſter were fruſtrated. His active mind, however, led him to wiſh for uſeful employment; and the reputation which he had acquired induced the elector of Mentz to appoint him preſident of the univerſity of that city. He hailed the dawnings of the French revolution, ſays M. Pougens, little apprehending, we may ſay, the clouds that ſubſequently overſhadowed them; and he was deputed by the people of Mentz, who had formed themſelves into a convention, to repair to Paris, and to requeſt that they might be united to the French republic. But whilſt he was thus employed, the city of Mentz was beſieged and taken by the Pruſſian troops. By this diſaſter he loſt his whole property, and his numerous MSS., which fell into the hands of the prince of Pruſſia. The domeſtic uneaſineſs of a conjugal kind, which he afterwards experienced, led him to form a reſolution of viſiting Hindooſtan and Thibet; for which he acquired the neceſſary preparation, by ſtudying the oriental languages: but the chagrin occaſioned by his misfortunes aggravating a ſcorbutic affection, which he had contracted during his voyage round the world, prevented the accompliſhment of his purpoſe, by terminating his exiſtence; which event took place at Paris, February 13th, 1792, at the age of 39 years. His works are "A Voyage round the World, in his Britannic Majeſty's Sloop Reſolution, commanded by Captain James Cook, during the Years 1772, 3, 4, and 5," London, 1777, 3 vols. 4to. This work was tranſlated by himſelf and his father into German, and publiſhed at Berlin, in 2 vols. 4to. 1778-1780. "Reply to Mr. Wales's Remarks on Mr. Forſter's Account of Captain Cook's laſt Voyage," London, 1778, 4to. "A Letter to the Right Honourable the Earl of Sandwich," 1779, 4to. He was concerned for ſome time with profeſſor Lichtenberg of Gottingen, in the publication of the Gottingen Magazine; he alſo wrote ſome papers in the Tranſactions of the Academy of Sciences at Upſal; he had a large ſhare in the "Characteres generum Plantarum, &c." of his father; and was employed by profeſſor Pallas, and others, in the continuation of Martini's Dictionary of Natural Hiſtory. Account of his Life by Pougens. Gen. Biog.

Forster's *Bay*, in *Geography*, a bay of the South Atlantic ocean, on the coaſt of Sandwich Land, between South Thule and cape Briſtol.

Forster's *Harbour*, a bay in Hudſon's ſtrait, Hudſon's bay. N. lat. 62° 18'. W. long. 73° 30'.

FORSTERA, in *Botany*, ſo named by Linnæus a little before his death, and publiſhed by his ſon in the *Supplementum Plantarum*, in honour of the celebrated naturaliſts, John Reinhold Forſter, and his ſon George Forſter; ſee thoſe articles. Linn Suppl. 59. G. Forſter in Act. Nov. Upſal. v. 3.184. Schreb. 607. Willd. Sp. Pl. v.4. 147. Juſſ. 423. Swartz in Schrad. Journ. for 1799. 31. t. 2. and in Sims and Kon. Ann. of Bot. v. 1. 291. t. 6. (Phyllachne; Forſt. Gen. t.58. Linn. Suppl. 62. Schreb. 672. Juſſ. 422.)

422.) Class and order, *Gynandria Diandria*. Nat. Ord. *Campanaceæ*, Linn.

Gen. Ch. *Cal.* Perianth double; one *inferior*, of two or three erect leaves; the other *superior*, of from two to six erect leaves. *Cor.* of one petal, tubular, somewhat bell-shaped; tube short; limb in five or six deep, equal, oblong, spreading segments. *Stam.* Filaments none; anthers two, sessile on the summit of the style, globose, of one cell and two valves, which separate transversely at their outside. *Pist.* Germen inferior, turbinate; style columnar, cylindrical, erect; stigmas two, roundish, concealed by the concave upper valves of the anthers. *Peric.* Capsule oval, of one cell. *Seeds* numerous, inserted upon a central columnar receptacle.

Ess. Ch. Calyx double; inferior of two or three leaves; superior of three to six leaves. Corolla tubular, bell-shaped, in five or six segments. Capsule of one cell. Seeds numerous.

Obs. The above characters are taken from Swartz, who first well understood this singular genus, as well as *Phyllachne* of Forster and Linnæus, which he unites with it. He has hinted, and Mr. Konig in the Annals of Botany confirms the idea, that *Forstera* and some other kindred genera, constitute a new natural order, next to the *Campanaceæ* of Linnæus, *Campanulaceæ* of Jussieu. These genera are *Lobelia*, *Goodenia*, *Scævola*, *Velleia*, *Stylidium*, and possibly one or two more. The latter is the *Ventenatia* of Dr. Smith in his *Exotic Botany*, t. 66, 67, communicated originally by him, under the name of *Stylidium*, to his friend professor Swartz, who published it in the Transactions of the Natural History Society of Berlin, and this name must remain, there being now another *Ventenatia*.

1. F. *sedifolia*. Linn. Suppl. 407. Forst. Act. Nov. Upsal. v. 3. 184. t. 9. Prod. 61.—Stems ascending. Leaves reflexed, obtuse. Flower-stalk elongated. Outer calyx shortest.—Native of high mountains in New Zeeland, where it was discovered by the botanists whose name it bears. The *roots* are perennial, creeping. *Stems* several, ascending, lax, a span high, sub-divided, leafy. *Leaves* loosely imbricated, tongue-shaped, obtuse, entire, recurved, thickish, shining, with a broad keel. *Flower-stalks* terminal, solitary, a finger's length, simple, naked, smooth, single-flowered. *Flower* erect, white, or flesh coloured, red in the orifice, the size of *Androsace lactea*. This is a very rare plant in herbariums, and unknown in gardens, though highly desirable, and unquestionably hardy.

2. F. *muscifolia*. Willd. Sp. Pl. v. 4. 148. (Phyllachne uliginosa; Linn. Suppl. 412. Forst. Magell. 32.)—Stems densely tufted. Leaves closely imbricated, acute. Flower-stalk very short. Outer calyx longest. Native of Terra del Fuego. In habit this pretty plant resembles a moss, forming very compact level tufts. The *stems* when separated are found covered with imbricated, keeled, acute *leaves*.

The *flowers* are small, solitary, terminal, almost sessile, imbedded as it were in the top leaves, white or flesh-coloured, resembling those of the smallest kinds of *Androsace*, to which genus any alpine botanist would, at first sight, suppose this species to belong.

FORSYTHIA, in honour of the late Mr. William Forsyth, F. A. S. and F. S. A. gardener to his majesty at Kensington, author of a Treatise on the Culture and Management of Fruit-trees. He is celebrated for the discovery of a composition for protecting wounded trees from the injuries of the air, and so enabling them to heal, for which he was rewarded by parliament. This genus was named by Vahl, the original *Forsythia* of Walter, Flo. Carolin. 153, proving no other than the *Decumaria barbara* of Linnæus; see DECUMARIA.

This was unknown to Mr. Walter, who therefore does not merit the censure cast on him by Vahl, of changing an established name to no purpose. Vahl. Enum. v. 1. 39. Class and order, *Diandria Monogynia*. Nat. Ord. *Sepiariæ*, Linn. *Jasmineæ*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, in four deep, lanceolate, equal segments. *Cor.* of one petal, bell-shaped, cut half way down into four ovate, obtuse lobes. *Stam.* Filaments two, very short; anthers oblong, furrowed, the length of the calyx. *Pist.* Germen superior, ovate, smooth; style thread-shaped, the length of the calyx; stigma capitate, two-lobed. *Fruit* unknown, supposed by Thunberg to be a capsule.

Ess. Ch. Calyx in four deep segments. Corolla bell-shaped, four-cleft. Fruit . . . . .

1. F. *suspensa*, the only known species. (Syringa suspensa; Thunb. Jap. 19. t. 3. Linn. Syst. Veg. ed. 14. 57. Mart. Mill. Dict. v. 4. Willd. Sp. Pl. v. 1. 49. Rengjo; Kæmpf. Amoen. 907.)—Native of Miaco and other parts of Japan, where also it is cultivated for the beauty of its flowers, which come forth in April, before the leaves, but soon fall off. It is a *shrub*, with a climbing *stem*, and long, trailing, opposite, pendulous, smooth *branches*. *Leaves* several from each bud, stalked, ovate, acute, serrated, smooth, thin; the earlier ones simple; the rest ternate. *Flowers* from several opposite buds, towards the ends of the branches, about the size of the blossoms of *Halesia tetraptera*; but yellow, streaked internally with red, each hanging from a simple slender stalk, near an inch long. Willdenow justly remarks that this plant is totally unlike the real species of *Syringa*, and might well constitute a distinct genus, which Vahl carried into effect, though the fruit is as yet unknown to botanists.—The *Forsythia* would be a desirable acquisition for our gardens, being doubtless able to bear our climate as well as the Chinese *Hydrangea*, and calculated for decorating bowers, treillis-work, &c. If botanists would take the pains to furnish travellers with drawings of such plants, even if made but imperfectly from any drawings, plates and descriptions that happen to exist, many valuable species might still be obtained from China and Japan. By such a method, at the command of the present queen of Great Britain, the fragrant *Acorus gramineus*, Dryand. in Ait. Hort. Kew. v. 1. 474, frequently drawn on Chinese papers, as cultivated in pots about houses, was obtained, and first made known to botanists; except indeed that it seems to be the *Acorus Calamus* of Loureiro.

FORT, RAIMOND-JEAN, in *Biography*, called also in Latin *Janfortius*, a physician of distinguished talents, by which he was raised to the highest rank in the profession, although of low origin. He was born at Verona of poor parents, who were unable to afford him any education: but a person of that city, who had remarked his quickness and desire for knowledge, procured him instruction in reading and writing, and afterwards sent him to Padua, where he distinguished himself among his fellow-students in the classes of humanity. This kind patron continued to support him also during his application to the study of medicine, which he honourably terminated by taking the degree of Doctor. He had scarcely quitted the schools, however, before the death of his protector left him without resource. He repaired to Venice, where he was relieved from poverty by the commencement of a small, but successful practice of his profession. Pressed as he was by the difficulty of subsistence, he did not resort to the unworthy means

means of obtaining notoriety, which effrontery and intrigue often lead men to adopt in great cities; he conducted himself with a modesty that is usually the concomitant of a sound understanding. By this mode of conduct he gradually acquired the reputation of one of the most able physicians of Venice; a character which was sanctioned by the senate, who appointed him to the first professorship of medicine in the university of Padua. This office he fulfilled to the admiration of all: for he was not less eloquent in his lectures, than accurate in his observations and prognostics, and successful in his cures. In 1676 the emperor Leopold commanded his attendance at Vienna, in order to consult him respecting his own health: and he gave so much satisfaction to that prince, that he returned to Padua loaded with magnificent presents, and decorated with the title of medical counsellor to the imperial court. The senate of Venice granted him the additional honour of the knighthood of the order of St. Mark, with an augmentation of his stipend, and likewise appointed him honorary professor of Padua. He did not however long enjoy these well-merited honours, for he died at Padua on the 26th of February, 1678, in the 75th year of his age.

This physician was the author of several practical works, of which the following are the titles. 1. "Consilia de Febribus et morbis Mulierum facilè cognoscendis et curandis," Patavii, 1668, folio. 2. "Consultationum et Responsionum Medicinalium centuriæ quatuor," tomus primus, Patav. 1669. fol. Geneva, 1677. 3. A second volume of the same book, at Padua, 1678. And 4. "Consultationes et Responsiones Medicinales," in two volumes, folio, Padua, 1721, which comprehends the two preceding works.

FORT, FRANCIS LE, was descended from a noble family of Geneva, where he was born in 1656, and entered at an early age into the military service of France. He afterwards served as a volunteer in Holland, and was wounded at the siege of Grave. For the sake of preferment he joined a German colonel, who was enlisting a body of men for the czar Alexis of Russia. They arrived at Archangel, and were exposed to extreme danger and want. Le Fort, however, contrived to get to Moscow, and was by his address immediately appointed secretary to the Danish resident. He applied himself to, and soon acquired, the languages necessary to his new situation, and attracted the notice of several persons of distinction, and finally of the young czar Peter. In him he found a patron, and Le Fort was precisely the person wanted to assist the prince in his efforts to raise himself and his country from that state of barbarism in which it was involved at this period. He was immediately promoted to a captain's commission, and was admitted to the confidence of the sovereign. He was employed to raise a body of 12,000 men, and was made their general. Though perfectly unacquainted with naval affairs, he was, soon after, created an admiral, and his activity rendered him very useful in forming the commencement of that marine which was the favourite object of the czar's life. Fort was appointed in 1696 to conduct the siege of Asoph, in which he gained so much reputation that the czar immediately invested him with the chief command of all his troops both by land and by sea. He was appointed to the government of Novogorod, and to the principal post in the ministry. When Peter determined upon travelling for his own improvement, he sent Le Fort embassador to the courts which he intended to visit, and went as a private person in his suite. Though he was ever in high esteem with his master, yet he once narrowly escaped with life, the czar having, in a fit of passion, drawn his sword upon him. When Peter was returned to his recollection he expressed the most unfeigned sorrow for what had happened, and Le Fort retained his favour till his death, in 1699. The czar honoured him with a public funeral, and followed in the procession as a military officer. Le Fort was not a man of extensive knowledge when he was introduced into the Russian service, but he had the seeds of great talents in him, which developed themselves in proportion to his advancement: and he had seen enough of the world to be able to suggest plans on which the improvement of the country depended. Moreri.

FORT, a little castle or fortress; or a place of small extent, fortified by art or nature, or both.

A fort is a work encompassed round with a moat, rampart, and parapet, to secure some high ground, or passage of a river; to make good an advantageous post; to fortify the lines and quarters of a siege.

FORT, *Field*, otherwise called *Fortin* or *Fortlet*, and sometimes *Sconce*, is a small fort, built in haste, for the defence of a pass or post; but particularly constructed for the defence of a camp in the time of a siege, where the principal quarters are usually joined, or made to communicate with each other, by lines defended by fortins and redoubts. Their figure and size are various, according to the nature of the situation, and the importance of the service for which they are intended. Some are fortified with bastions, and some with demi-bastions. A fort differs from a *citadel*, (which see,) as this last is erected to command and guard some town; and from a redoubt, as it is closed on all sides: whereas a redoubt is open on one side. Forts are most commonly made square (see *Plate* IV. *Fortification, fig.* 4.) especially when the pass they are to guard is of any consequence, or the place may easily be approached: the sides of this square are a hundred toises, the perpendicular ten, and the faces twenty-five; the ditch about this fort may be from ten to twelve toises; the parapet is to be made of turf, and fraised, and the ditch palisadoed when dry. There may be made a covert-way about this fort, or else a row of palisades might be placed on the outside of the ditch. A square fort may be fortified in the following manner: having inscribed the square in a circle, divide each of its sides, A B, B D, &c. into two equal parts in the points F, M, &c. from the centre E draw an indefinite line E F; from the centre draw also the lines E A, E B, E D, E C, to the angles of the square; divide the side A B into eight equal parts, and set off one of these parts from F to G, and from G draw the lines of defence A G, B G; divide another side of the square into seven equal parts, and set off two of those parts from A to K, and from B to L, which will be the faces of the bastions; take the distance K L in your compasses, and set it off on the lines of defence from K to H, and from L to I, and draw H I, which will be the curtin, and the lines K I, L H, will be the flanks. Or, it may be otherwise fortified thus: let the side A A (*fig.* 5.) be a hundred and thirty fathoms; the demi-gorge A B twenty-five fathoms; and with the compasses opened to the length of the pinched line B C B, which is the diagonal of two sides, from each of which there has been taken twenty-five fathoms, upon the extremity opposed to the angle which they form, describe two arcs above the angle of the figure, alternately making use of the points B for centres; then draw lines from the points of intersection of the arcs D, to the point which served for centres B, upon which points B, raise the flanks B E perpendicular to the opposed lines of defence B D.

FORT *paine, & dure.* See PAINE.

FORT *royal*, is a fort whose line of defence is at least twenty-six fathoms long.

FORTS,

FORT, *Star*, is a ſconce or redoubt, conſtituted by re-entering and ſalliant angles, having commonly from five to eight points, and the ſides flanking each other.

To deſcribe a ſtar-fort.—Deſcribe a hexagon *a* B C *d e f* (*fig.* 6.); divide one of its ſides into four equal parts; and on the centre of this ſide raiſe the perpendicular D A equal to one fourth of the ſide B C. From the point A draw the faces A C and A B, and let the ſame operations be performed with reſpect to the other ſides of the hexagon.

FORTS are ſometimes made triangular, only with half baſtions, as in *fig.* 7. This, as well as the ſquare and pentagonal fort, (*figs.* 8. and 9.) may be deſcribed in the following manner. Parallel to the inner figure, whether it be a triangle, ſquare, or pentagon, whoſe ſide A B may be ſuppoſed about eighteen yards, deſcribe an outward figure at the diſtance of about four or five yards from it, or farther, if neceſſary, whoſe ſides are E D, E F, &c. Divide each ſide, as E D, E F, &c. into three equal parts, one of which is E I, F L, &c. and in theſe ſides prolonged, take D G, E H, &c. each equal to one of thoſe three parts. From the points G, H, &c. thus found, draw the lines of defence to the angles of the outward figure, as H D, &c. and from the points I, L, &c. draw the flanks I K, L M, &c. perpendicular to the ſides E D, E F, meeting the lines of defence in K, M, &c. Or the flanks may be drawn, by continuing the line D I towards E, and taking I P equal to twice I E; from P as a centre, with the radius P I, cut the line of defence in K, and draw the flank I K. Then to each face H K, flank K I, and curtin I G, make a parapet of about ſeven feet thick, or more if neceſſary, expreſſed in the figures, by drawing lines at that diſtance on the inſide of the ſeveral parts. Leave a proper berm of about four or five feet broad, and make a ditch about five or ſix yards wide, whoſe outer line or counterſcarp is to be parallel to the faces and curtins only. A fort thus conſtructed is more capable of defence than one without flanks; for the curtin I G is defended by the flank I K; and the face H K has ſome defence from the part D G. In the conſtruction of triangular forts, (*fig.* 10.) inſtead of making half baſtions at the angles, whole ones are placed in the middle of the ſides. The gorges of theſe baſtions may be from twenty or twenty-four toiſes, when the ſides are from a hundred to a hundred and twenty; the flanks are perpendicular to the ſides, from ten to twelve toiſes long, and the capitals from twenty to twenty-four. If the ſides happen to be greater or leſs, the parts of the baſtions are likewiſe made greater or leſs in proportion: the ditch round this fort may be ten or twelve toiſes wide. The ramparts and parapets of theſe works are commonly made of turf, and the outſide of the parapet fraiſed. Forts are often made of various figures, regular or irregular, and ſometimes in the form of a ſemi-circle, eſpecially when they are ſituated near a river, ſea, or at the entrance of a harbour; by which figure they are able to fire at the ſhips on all ſides. When a fort is to be built on a neck of land formed by the confluence of two rivers, or in the windings of a river, in order to prevent an enemy from tranſporting any thing by water, or to prevent their ſhips paſſing that way, the figure of the fort muſt be adapted to the ſituation, in ſuch a manner, that there may be no place for landing troops out of the reach of the fire of ſome work or other; and the ſide next to the land ſhould always be better fortified than the other parts near the river, as being more liable to an attack. There are two principal errors committed in the conſtruction of forts near the ſea, or navigable rivers, which ſhould be carefully guarded againſt; the one is, that of making the parapet too low, ſo that perſons behind it may be fired upon from the round top of a maſt, by which the gunners are obliged to abandon their guns, and ſave themſelves by flight: to remedy this inconvenience, the parapet ſhould be nine or ten feet high, and the batteries may be covered above by making an arch over every piece, left open behind to let out the ſmoke, or with planks, like ſheds, over which may be ſcattered earth or dung about a foot and half thick, to prevent the wood from taking fire.

The other fault is, leaving forts or batteries open behind, or very little fortified towards the land, ſo that the enemy may land men in the dark and ſurprize them, by which the guns placed in them become not only uſeleſs, but ſerve rather to deſtroy them. A fort, or battery, therefore, ſhould be fortified all round with a good rampart and ditch, at leaſt, or with an addition of outworks, if the place is of any importance: the rampart ſhould be fraiſed, and the ditch have a row of paliſades planted in the middle of it, if it be dry. In the conſtruction of all forts, it ſhould be remembered, that the figure of feweſt ſides and baſtions, that can probably anſwer the propoſed defence, is always to be preferred; as works on ſuch a plan are ſooner executed, and with leſs expence: beſides, fewer troops will ſerve, and they are more readily brought together in caſe of neceſſity. See *Military* CONSTRUCTION.

FORTS, *Vitrified*, ſtructures of a ſingular kind, occurring in the Highlands and northern parts of Scotland, the walls of which ſeem to have been melted into a ſolid maſs, reſembling the lava of a volcano. Mr. Williams, an engineer, ſuggeſts, in a treatiſe upon the ſubject, that theſe walls are the works of art; whilſt others are of opinion, that they ſhould be traced to a volcanic origin. Theſe buildings are commonly ſituated on the ſummits of ſmall hills, commanding extenſive views of the adjacent vallies or of the country below them. The area on the eminence, varying in extent, as ſome have ſuppoſed, in proportion to the number of cattle which the proprietor had to protect, or the dependents he was obliged to accommodate, was ſurrounded with a high and ſtrong wall, the ſtones of which were for the moſt part entirely melted; while others, which are not ſo completely fuſed, are ſo far ſunk in the vitrified matter as to be quite incloſed in it; and the fuſion of ſome has been ſo perfect, that the ruins reſemble maſſes of coarſe glaſs. Among thoſe who allow theſe vitrified ſtructures to be artificial works, ſome maintain that they were vitrified for the purpoſe of cementing the materials together; whilſt others think that the vitrification is accidental. Mr. Tytler, in his diſſertation, ſuggeſts that theſe forts were conſtructed, not only before the Roman invaſion, but before the introduction of the Druidical rites into Britain.

FORT is alſo uſed as a *geographical* appellative in various inſtances; ſome of which we ſhall recite.

FORT *Amſterdam*, a fortreſs of Africa, on the Gold coaſt, near Little Cormantin, whence the Engliſh were expelled by the Dutch in 1665.

FORT *Ann*. See ANN.

FORT *Auguſtus*. See AUGUSTUS.

FORT *des Ajutels*, a fort of France, in the department of the Channel; four miles N.W. of Cherburg.

FORT *Badenſtein*, a fort of Africa, on the Gold coaſt, belonging to the Dutch.

FORT *Barnevelt*, a fort on the ſouth coaſt of the iſland of Bachian, garriſoned by the Dutch. See BACHIAN.

FORT *Barrington*, a town of America, in Georgia, on the coaſt of the Atlantic; 50 miles S.S.W. of Savannah. N. lat. 31° 30′. W. long. 81° 55′.

FORT *La Bay*, a fort on the ſouthern extremity of a bay in lake Michigan, denominated by the French the "bay of

of Puants," but called by the Engliſh, ſince they have had poſſeſſion of it, the "Green bay," from its appearance. It is ſurrounded by a ſtockade, and garriſoned by the Engliſh with an officer and 30 men.

Fort *Bourbon*. See Bourbon.

Fort *de Broto*, a fort on the N. coaſt of Sicily; nine miles W.N.W. of Pati.

Fort *Chamblee*. See Chamblee.

Fort *Charles*, a fort at the S.W. extremity of the iſland of Barbadoes, S. of Bridge-town, and terminating Charles's bay.

Fort *Charlotte*, a fort on the iſland of Shetland or Mainland, firſt built by Oliver Cromwell, to defend the town and harbour of Lerwick; its name was given to it in 1781, when it was repaired and garriſoned: one mile N.W. of Lerwick.

Fort *Chippeway*. See Chippeway.

Fort *Chriſtianſburg*. See Christiansburg.

Fort *Church-hill*. See Church-hill.

Fort *Clarendon*, a fort on the weſtern ſide of the iſland of Barbadoes, between Speight's town and Hole town.

Fort *Conde de la Mobile*, a fort of Weſt Florida, at the N. extremity of Mobile bay. N. lat. 30° 34′. W. long. 88° 2′.

Fort *Crevecœur*, a fort of Africa. See Crevecoeur.—Alſo, a fort of America, in Weſt Florida, in St. Joſeph's bay. N. lat. 29° 51′. W. long. 85° 30′.

Fort *Culonge*, a fort of Lower Canada, on the Utawas; 170 miles W. of Montreal.

Fort *Cumberland*. See Cumberland.

Fort *Dauphin*, a ſea-port of the iſland of Hiſpaniola, in the Weſt Indies, ſituated on the N. ſide of the iſland, with a ſpacious harbour. N. lat. 19° 42′. W. long. 72° 40′. See Dauphin.

Fort *Delagarta*, a fort on the coaſt of Portugal; ſeven miles N.N.W. of Viana.

Fort *Detroit*. See Detroit.

Fort *Edward*, a town of America, in New York, ſo called from its fortifications, now diſmantled; 33 miles N. of Albany.

Fort *Erie*. See Erie.

Fort *de Eſtrica*, a fort of Portugal, in the province of Entre Duero é Minho; 20 miles N. of Braga.

Fort *di Faro*, a fort and light-houſe, on the N.E. coaſt of Sicily. N. lat. 38° 15′. E. long. 16°.

Fort *de Ferrières*, a fortreſs of France, in the department of the Tarn; 10 miles E. of Caſtres.

Fort *Fontanelle*, a fort of Barbadoes, in St. Michael's pariſh, on the W. coaſt N. of Bridge-town.

Fort *Franklin*, a fort of America, in Pennſylvania, erected in 1787, at a place formerly called "Venango," on the Allegany river, 46 miles S. of lake Erie. N. lat. 41° 23′. W. long. 79° 50′.

Fort *Frederick Henry*, a fort of Brabant, at the mouth of the Scheldt; 10 miles N.W. of Antwerp.

Fort *Frontenac*, a fort of N. America, in lake George, taken from the French in 1756, though defended by 60 pieces of cannon, and 100 men, beſides Indians.

Fort *de Fuentes*, a fortreſs of Italy, at the place where the Adda enters the lake of Como; deſtroyed by the French in 1796; 30 miles N. of Como.

Fort *Galet*, a fortreſs on the coaſt of France; half a mile N. of Cherburg.

Fort *George*, a regular fortification of Scotland, in the county of Inverneſs, ſituated on a long and narrow neck of land called "Ardarſier," ſurrounded on three ſides by the ſea, covering ten acres, begun in the year 1747, and completed in twenty years at an expence of 160,000*l*. It is capable of containing 10,000 men, with barracks for 6000. It mounts 100 cannon, moſtly 42-pounders; 11 miles N.E. of Inverneſs.—Alſo, a fort of America, in New York, at the ſouth extremity of lake George; 42 miles N. of Albany.

Fort, *Half-moon*, a fort of Barbadoes, on the W. coaſt, N. of Speight's-town.

Fort, *Hallets*, a fort of Barbadoes, on the W. coaſt in the pariſh of St. Michael, N. of Bridge-town, and near Fontanelle fort.

Fort *Hamilton*, a fort of the weſtern territory of America, on the Meami. N. lat. 39° 18′. W. long. 84° 50′.

Fort *Hardy*, a fort of America, in the ſtate of New York; 25 miles N. of Albany.

Fort, *Haywood's*, a fort of Barbadoes, near Speight's-town.

Fort *de Hue*, a fort of France, in the department of the Channel; three miles E. of Cherburg.

Fort *Hommet*, a fort of France, in the department of the Channel; two miles N.W. of Cherburg.

Fort *James*, a fort of Africa, on the Gold coaſt.

Fort *Jefferſon*, an American fort in Kentucky, on the Miſſiſſippi. N. lat. 36° 36′. W. long. 89° 46′.—Alſo, a fort in the weſtern territory of America, on White river. N. lat. 39° 58′. W. long. 85° 25′.

Fort *Knox*, a fort in the weſtern territory of America; on White river. N. lat. 39° 37′. W. long. 85° 10′.

Fort *Leon*, a fort of Louiſiana, on the Miſſiſſippi; five miles S. of New Orleans.

Fort *Leſſa*, a fort on the W. coaſt of Portugal; five miles N.W. of Oporto.

Fort *Leydſaambeyde*, a Dutch fort on the Gold coaſt.

Fort *Ligonier*, a fort of America, in Pennſylvania, 36 miles E. of Pittſburg. N. lat. 40° 16′. W. long. 79° 15′.

Fort *Longlet*, a fort on the coaſt of France, near Cherburg.

Fort *Louis*, now called *fort Vauban*, a fortreſs of France, in the department of the Lower Rhine, built by Louis XIV. on an iſland formed by the Rhine; 18 miles N.N.E. of Straſburg.—Alſo, a fort of Senegal, built by the French, but taken in 1758 by the Engliſh.—Alſo, a fort on the ſouth coaſt of Hiſpaniola.

Fort *Marlborough*. See Bencoolen.

Fort *Mackintoſh*, a fort of America, in Pennſylvania, on the Ohio; 22 miles N.W. of Pittſburg. N. lat. 40° 42′. W. long. 80° 21′.

Fort, *Maywek's*, a fort of Barbadoes, in St. Lucy's pariſh, N. of Speight's-town.

Fort *Meami*, a fort of N. America, on the Meami. N. lat. 41° 20′. W. long. 84° 56′.

Fort *Medoc*, a fort of France, on the river Garonne, oppoſite to Blaye.

Fort *Mirabouc*, a fort of France, in the department of the Po; 10 miles W. of Pinerolo.

Fort *Mooſe*, a fort at the ſouth end of St. James's bay, in Hudſon's bay, at the mouth of Mooſe river.

Fort *Naſſau*, a fortreſs of Brabant, on the Scheldt, between Tolen and Berg-op-zoom.—Alſo, a fortreſs of Africa, on the coaſt of Guinea, with a good harbour, built by the Dutch in 1612.—Alſo, a fort on the north coaſt of the iſland of Timor.—Alſo, a fort on the iſland of Cadſand.

Fort *Nieulet*, a fortreſs of France, near Calais and the ſea, ſerving to guard the ſluices.

Fort *Omonville*, a fort of France, on the N. coaſt of the department of the Channel; eight miles W.N.W. of Cherburg. N. lat. 49° 43′. W. long. 1° 44′.

Fort *Oſwegatchy*, a fort of Upper Canada, on the S. ſide of the river St. Lawrence; 60 miles N.E. of lake Ontario.

Fort *Panmure*, a fort of America, in the country of the Natches.

Fort *Patience*, a fortreſs of Flanders, on the coaſt oppoſite to Zealand, between Sas de Ghent and Yſendick.

Fort *Penthievre*, a fort of France, in the department of the Morbihan, ſituated on the peninſula of Quiberon; 15 miles S.E. of L'Orient. N. lat. 47° 33′. E. long. 3° 3′.

Fort *Philippe*, a fortreſs of France, in the department of the North; 2 miles from Gravelines.

Fort *Portage*, a port of Upper Canada, on the river Utawas; 120 miles W. of Montreal.

Fort *de Porto de Cam*, a fort on the weſt coaſt of Portugal, near the Atlantic; 6 miles N.N.W. of Viana.

Fort *de Porta*, a fort on the weſt coaſt of Portugal, near the Atlantic; 5 miles N. of Viana.

Fort *de Povoa*, a fort of Portugal, in the province of Entre Duero é Minho; 1 mile N. of Villa de Conde.

Fort *Queen*, a fort of Barbadoes; 1 mile N. of Hole town.

Fort *Querqueville*, a fort of France, in the department of the Channel; 3 miles N.W. of Cherburg.

Fort *de Rego de Foz*, a fort on the weſt coaſt of Portugal, near the Atlantic; 2 miles N.W. of Viana.

Fort *Royal*, a fort of Africa, built by the Danes, and called "Frederickſburg;" but its name was changed when the Engliſh became the poſſeſſors of it.—Alſo, a town of the iſland of Martinico, ſituated on the ſouth coaſt. N. lat. 14° 34′. W. long. 61°.—Alſo, a fort built by the French on the weſt coaſt of the iſland of Martinico.—Alſo, a town, called "St. George," ſituated on a ſpacious bay on the weſt coaſt of the iſland of Grenada, and capital of the iſland. This town poſſeſſes one of the ſafeſt and moſt commodious harbours for ſhipping in the Engliſh Weſt Indies, and has been not long ago fortified at a very great expence. It is built chiefly of brick, and divided by a ridge, running into the ſea, and forming on one ſide the "Carenage," and on the other the bay: ſo that there is the "Bay-town," with a handſome ſquare and market-place; and the "Carenage-town," in which the merchants principally reſide; the ſhips lying land-locked, and in deep water, cloſe to the wharfs. On the ridge ſtands the church, and on the promontory above it is a large old fort, built of ſtone, and large enough to accommodate an entire regiment. N. lat. 12° 4′. W. long. 61° 32′.

Fort *St. Anthony*, a fort of Africa, on the Gold coaſt, in the country of Axim, belonging to the Dutch.

Fort *St. Catalina*, a fort of Portugal, in the province of Beira; 2 miles S. of Villa Nova de Moncarras.

Fort *St. David*, or *Tegapatam*, a fortreſs of Hindooſtan, on the coaſt of Coromandel, ſeated on a branch of the river Panaur, in a ſmall tract of country bought of a Mahratta prince for 30,000*l.*, and firſt built in the year 1686, for the uſe of the Engliſh Eaſt India company, and much ſtrengthened about the year 1750 by Mr. Robins. It is the ſtaple of this country for fine dimities and painted cottons. About four miles from the fort is a famous Indian fig-tree, under the ſhadow of which it is ſuppoſed 10,000 perſons may ſtand without inconvenience; 1 mile N. of Cuddalore.

Fort *St. Donas*, a fortreſs of Flanders, built by the Spaniards, between Dam and Sluys.

Fort *St. George*. See Madras.

Fort *St. Joſeph*. See Gallam.

Fort *St. Julian*, a fort of Portugal, on the north ſide of the mouth of the Tagus; 9 miles below Liſbon.

Fort *St. Julien*, a fort of Egypt, on the left branch of the Nile, between Roſetta and the ſea.

Fort *St. Lucar*, a fort of Braſil, at the mouth of the river Jaguaripe. S. lat. 4° 2′.

Fort *de St. Martino*, a fortreſs of Etruria, built by Coſmo the Great, on a mountain near the river Sieve; 10 miles N. of Florence.

Fort *St. Martin de Ré*, a fortreſs of France, in the iſland of Ré, near the town of St. Martin.

Fort *St. Mary*, a fortreſs on the eaſt coaſt of the iſland of Guadaloupe.—Alſo, a fortreſs of Genoa, on a rock nearly ſurrounded by the ſea.—Alſo, a fort of Weſt Florida, on the eaſt ſide of the river Miſſiſſippi; 6 miles S.E. of New Orleans.

Fort *St. Michel*, a fortreſs of Spain, in Eſtramadura, near the town of Badajoz.—Alſo, a fortreſs of France, on the Meuſe, oppoſite to Venlo.

Fort *St. Nicolas*, a fortreſs of Dalmatia, near the town of Sebenico.

Fort *St. Philip*, a fortreſs of the iſland of Minorca, ſituated on a rock near the coaſt, to defend port Mahon.—Alſo, a fortreſs of the iſland of Tercera, near the town of Angra.

Fort *de St. Tiago*, a fort of Portugal, on the coaſt of the Atlantic, in the province of Entre Duero é Minho; 7 miles N.N.W. of Viana.

Fort *St. Yago*, a town of South America; 10 miles N. of Cumana.

Fort *Saſtingue*, a fort of Flanders, on the Scheldt, between Hulſt and Berg-op-zoom.

Fort *Schloper*, a fort of Upper Canada, near the falls of Niagara.

Fort *Sinclair*, a fort of America, on the right bank of the river Hudſon. N. lat. 43° 15′. W. long. 82° 21′.

Fort *Stanwix*, a ſmall ſquare log fort, in the ſtate of New York, defended with four baſtions, and a ſtockaded covert way, without any other out-works.

Fort *Tete*, a fort and town of Africa, in Mocaranga, on the Zambeſe. S. lat. 16° 5′. E. long. 33° 3′.

Fort *Trinité*, a fort on the weſt coaſt of the iſland of Martinico.

Fort *de Verchères*, a fort of Canada, which took its name from that of a French lady who defended it in 1690, when it was attacked by the Iroquois Indians.

Fort *Urbino*, a fortreſs of Italy, in the department of the Amona; 13 miles E. of Bologna.

Fort *Wallis*, a fortification of the United States of America, on the North river, connected with Weſt point.

Fort *Waſhington*, a fort on the iſland of New York, on the eaſt ſide of Hudſon's river.—Alſo, a fort in the weſtern territory of United America, on the right bank of the Ohio; 10 miles W. of Columbia. N. lat. 38° 57′. W. long. 84° 45′.

Fort *Wedenburg*, a town of Africa, on the Gold coaſt.

Fort *Wentworth*, a fort of New Hampſhire, on the Connecticut. N. lat. 44° 32′. W. long. 71° 30′.

Fort *William*, a ſmall fortreſs of Scotland, in the county of Inverneſs, built in the reign of king William III. on the ſcite of a fort conſtructed by Cromwell, in a plain, on a navigable arm of the ſea, called Loch Eil, near the influx of the Lochy and Nevis. Although this is not a ſtrong place, it was gallantly defended againſt the rebels in 1746. Several years ago, a fourth part of the wall was undermined and ſwept away by the Nevis; nor is there any proſpect of its being repaired. It is occupied by a company of invalids. The village in its neighbourhood is called Maryborough.

A mile thence, at the mouth of the Lochy, is Inverlochy caſtle, at the foot of Beneviſh, a mountain 4,370 feet above the level of the ſea. A poſt-office was eſtabliſhed at Fort William in 1764; 130 miles N. of Edinburgh. N. lat. 56° 48′. W. long. 5° 6′.

Fort *William*. See Calcutta.

Fort *William-Henry*, a fort of America, in Pennſylvania, at the foot of the Blue Mountains; 20 miles N.W. of Reading.

Fort, *Fr.* loud; *temps fort*, the accented part of a bar, in *Muſic*. See Accent, Tact, and Trine.

FORTAMENTE, in the *Italian Muſic*, the ſame with forte.

FORTAVENTURA, or Fuerte-ventura, in *Geography*, one of the Canary iſlands, about 50 miles long, and from 8 to 24 broad. The ſoil is in general fertile in corn, roots, and fruits, and beautifully diverſified with hills and vallies, well watered, and ſupplied with a variety of timber. This iſland produces, beſides the other fruits common to the Canaries, abundance of dates, maſtic, and olives, with archil for dyeing, and a ſpecies of fig-tree, that yields a medicinal balm, as white as milk, but of virtues unknown in Europe. In Fortaventura a great quantity of goat-milk cheeſe is made; the iſland breeding annually more than 50,000 kids, each of which weighs between 40 and 50 pounds. The fleſh is fat, better coloured, and ſweeter than in any other country. The principal towns of this iſland are La Villa in the centre, and Olivia near the northern extremity; on the eaſt coaſt there are alſo three ſea-ports, called Langla, Tarrafata, and Pozzo Negro; and there are ſeveral villages. The number of inhabitants is about 10,000. The climate of this iſland and Lancerotta is exceedingly ſalubrious. N. lat. 28° 4′. W. long. 14° 32′.

FORTE, *Ital.* loud, in *Muſic*. This term is uſed in the ſeveral inſtrumental parts of a muſical compoſition, for enforcing the tones of a paſſage; to ſing loud, put out the voice, produce or draw a great degree of ſound from an inſtrument. It is likewiſe uſed to annul the effect of a preceding piano.

FORTE-PIANO, an Italian compound ſubſtantive, of the ſame import, in muſic, as chiaro-ſcuro in painting. Forte-piano is the art of enforcing or enfeebling ſounds in imitative melody, as is done in ſpeech, which it imitates. We not only ſpeak with different degrees of force, when animated and impaſſioned, but when calm and tranquil. Muſic, in imitating various accents and tones of ſpeech, ſhould imitate the intenſity and remiſſion, and be ſometimes loud, ſometimes ſoft, and ſometimes in a whiſper; and this is what the Italians in general mean by forte-piano. Theſe two words, tranſpoſed, imply the keyed inſtrument, which, from its power over loud and ſoft, at the pleaſure of the performer, is called a *Piano-forte*, which ſee, and Harpsichord.

FORTESCUE, *Sir* John, in *Biography*, an Engliſh judge, third ſon of ſir Henry Forteſcue, lord-chief-juſtice of Ireland, was born in the pariſh of Wear Gifford in Devonſhire, from whence he removed to Lincoln's Inn, and was made ſerjeant at law in 1430, he having already diſtinguiſhed himſelf as a ſound lawyer, and an excellent lecturer on the laws. In 1442 he was elevated to the chief juſticeſhip of the king's-bench, and was probably the principal adviſer of Henry VI., to whom, in all his misfortunes, he faithfully adhered. When the ſucceſs of Edward IV. obliged Henry to take refuge in Scotland, Forteſcue attended him, and it was at this period he was created chancellor of England. For his general attachment to the intereſts of his maſter, he was in 1461 attainted of high treaſon, and another perſon appointed chief juſtice in his ſtead. He was never acknowledged chancellor by Edward's government, nor did he ever exerciſe the office in England. In 1463 he accompanied queen Margaret, prince Edward, and others of the adherents of the houſe of Lancaſter, in their flight to Flanders, and paſſed many years upon the continent as an exile. In this ſituation he compoſed his celebrated work, entitled "De Laudibus legum Angliæ," addreſſed to prince Edward, ſon of Henry VI. with the expreſs purpoſe of giving him juſt notions of the laws and conſtitution of his country. This work was not publiſhed till the reign of Henry VIII. ſince which period it has gone through many impreſſions; the beſt edition is ſaid to be that of 1775, with notes by Mr. Gregor. When the affairs of the houſe of Lancaſter ſeemed to take a turn, he, in company with the queen and prince, came to England, and was taken priſoner after the battle of Tewkeſbury in 1471, which annihilated the hopes of the houſe of Lancaſter. Edward releaſed and pardoned him, but probably not till he had written or promiſed to write a retractation of a paper he had formerly compoſed and circulated againſt the right and title of the houſe of York. After this he lived in retirement, and in his privacy drew up a work in Engliſh, on "The difference between an abſolute and limited Monarchy, as more particularly regards the Engliſh conſtitution." He wrote ſome other treatiſes which have never been made public. He lived to the age of ninety; the time of his death is not exactly aſcertained, but he was interred in the pariſh church of Ebrighton in Glouceſterſhire, of which place he poſſeſſed the manor. His work "De Laudibus legum Angliæ," is written in Latin in the form of a dialogue, and is a valuable record of the grounds and principles of the laws of England as they were underſtood at that time, and of various circumſtances relative to the mode of education in the inns of court. It is, however, rather a panegyric of the common law than a fair compariſon of it with the civil or other foreign ſyſtems. His other work, "On the Difference between an abſolute and limited Monarchy," firſt publiſhed by lord Forteſcue, in 1714, was chiefly a repetition in Engliſh of what is ſaid in the other piece concerning the conſtitution of England, with the addition of ſome obſervations meant for the ſervice of king Edward. Biog. Brit.

Fortescue *Bay*, in *Geography*, a bay of South America, in the ſtraits of Magellan. S. lat. 53° 39′. W. long. 73° 22′.

FORTESSA, an iſland in the gulf of Venice. N. lat. 44° 40′. E. long. 14° 48′.

FORTH, one of the moſt conſiderable rivers in Scotland, riſes out of two lakes at the foot of a mountain called Ben Lomond, in the ſhire of Dumbarton, and running nearly from weſt to eaſt, the whole breadth of this part of the iſland, almoſt divides it into two parts. The length of the Forth, from the ſource to its confluence with the German ocean in a direct line, is upwards of ninety miles; but ſo ſinuous is the courſe, that calculating its various windings, the diſtance cannot be leſs than two hundred and fifty. This characteriſtic the river aſſumes when only an inconſiderable rill, whilſt it winds through the mountains, collecting the tributary ſtreams. Having received a large ſupply of water from the rivers Teuth, Ardoch, and Allan, it enters the extenſive plain termed the Carſe of Stirling, about ſix miles weſtward of that town. Of its ſinuoſity here ſome idea may be formed, when it is known that the diſtance from Stirling to Alloa by land is only ſix miles; but by water twenty-four. It here ſeems as if unwilling to leave the country, prolonging its ſtay by lengthening its courſe; which

Gilpin ſo ſtrikingly deſcribes. "In this ſinuous navigation, were the mariner to truſt entirely to the ſails, he would have to wait for the benefit of every wind round the compaſs ſeveral times over." In theſe meanders it forms numerous peninſulæ, on one of which, oppoſite to the caſtle of Stirling, ſtands a ruined tower, the only remaining veſtige of the abbey of Camburkenneth, formerly the moſt wealthy monaſtery in the kingdom. The turnings and windings of the river through a rich and diverſified country, the numerous manſions on its margin, the white ſails of the veſſels mingling with the trees in every direction, form a coup d'œil of intereſting and pictureſque ſcenery. After paſſing Alloa, it expands into a bay near twenty miles long, and of conſiderable breadth; which being ſhut in by the contraction of the river at Queen's ferry, where it is not more than two miles wide; and ſtill further by the ſmall fortified iſland of Inchgarvie, ſituated in its channel; forms one of the fineſt roadſteds in the iſland. Thence expanding into a frith, with ſeveral ſmall iſlands, and on one of which, May, a light-houſe is erected, it forms ſeveral excellent harbours, both on the northern and ſouthern banks; particularly Leith roads, where it is nine miles over; and waſhing the ſhores of Haddington and Fife, falls into the German ocean. The river abounds with various kinds of white fiſh, and ſeveral valuable ſalmon fiſheries are eſtabliſhed in the upper part of its courſe; particularly at Alloa, Kincardine, Torryburne, and Culroſs: and the frith uſually receives an annual viſit of a ſhoal of herrings, equal to thoſe frequenting other parts of the eaſtern coaſt. The Forth is navigable up to Stirling bridge for veſſels of eighty tons, and for merchant veſſels of any draft of water as far as Grangemouth, where it is joined by the canal, uniting this river with the Clyde. From this communication, the numerous harbours on the coaſts of the frith, and the inexauſtible ſtores of coal, iron ore, and lime-ſtone, as well as the manufactures of the counties of Perth, Fife, Stirling, and the two Lothians, occaſion ſuch a reſort of veſſels, that the tonnage of the Forth nearly rivals the Thames.

FORTH and *Clyde canal*, is a navigable cut, which, connecting the rivers Forth and Clyde, forms a junction between the German ocean and the Iriſh ſea. The utility of conjoining large rivers, for the purpoſe of extending their navigation, muſt be obvious to every reflecting mind, and in no inſtance did the geographical features of the country, and the circumſtances which imperiouſly called for the execution of ſuch a work, appear more ſtriking than in this. The two rivers appeared to look with wiſhful eyes towards each other, and a natural paſſage preſented itſelf through the mountains for conducting the union canal. Previous to this being made, the trade of this poſſeſſed no channel with the other ſide of the iſland, but by immenſe maritime diſtance round the Land's End; or by the leſs circuitous route, but dangerous paſſage of Pentland frith. Such an idea was conceived ſo early as the reign of Charles II., and the ſcheme met with ſome conſideration; but that was not an age for this kind of national improvement. It then lay dormant till the year 1723, when a ſurvey was made of the line of country by Mr. Gordon; ſtill the undertaking was declined by the conſideration of the expence. It was again revived in 1762; and a ſurvey made by a Mr. Mackell, and another by Mr. Smeaton in 1764. From theſe ſurveys the practicability of the plan was aſcertained, but its eligibility was yet queſtioned on the ground of the eſtimated expence, eighty thouſand pounds. In the mean while a ſmaller canal was projected to extend from Glaſgow to the Forth; parliament, however, refuſed to ſanction the ſcheme on account of the ſmallneſs of the ſcale. Mr. Smeaton was then called in again to make a ſurvey and eſtimate for cutting a canal, of ſuch a breadth and depth, as would admit coaſting veſſels to paſs from ſea to ſea. A ſubſcription was accordingly opened, a bill obtained for leave to execute the plan, and the whole being placed under the direction of the able engineer who ſurveyed the ground, the undertaking commenced on July 10, 1768. After expending 150,000*l.* and overcoming difficulties which ſeemed at firſt inſurmountable, it was rendered navigable as far as Stockingfield, where a branch, called Monkland, extends to the collieries to the eaſt of Glaſgow. The ſubſcription and an additional loan having been exhauſted, the work was here ſtopped, and in this ſtate it remained till the year 1784, when the company, having obtained 50,000*l.* by forfeited eſtates, and an act of parliament for varying the line, Mr. Robert Whitworth, being appointed engineer, began to proſecute with great vigour and effect the further execution of the original plan. On the 28th of July, 1790, this immenſe undertaking was completed, and the navigation opened from ſea to ſea. Thus, with the aid of the collateral branch, a communication is formed between the great emporium of the north, Glaſgow, and both ſides of the iſland. The whole length of the canal is thirty-five miles from the mouth of the river Carron, to Dulmoreburn-foot, on the banks of the Clyde; riſing and falling 160 feet, by means of 39 locks. In its courſe it paſſes over rocks, through precipices, deep moſſes, over quick-ſands, and in places is guarded by banks twenty feet high; croſſes two conſiderable rivers, the Kelvin, and Luggie, with numerous rivulets and ſtreams, by 10 large, and 33 ſmaller aqueducts or water bridges. That over the former river is a grand object, conſiſting of ſeveral arches, the centre one of which is 90 feet, forming an arcade 420 in the ſpan in length, and 65 feet high. Various roads alſo traverſe the canal by the aid of 33 draw-bridges. The dimenſions of it, though greatly contracted from the original deſign, are far ſuperior to any work of the kind in South Britain. The Engliſh canals are in general from three to five feet deep; from 20 to 30 feet wide; and the lock gates from ten to twelve feet; ſufficiently capacious however to anſwer the purpoſes of inland carriage, from one town to another, for which they were excluſively deſigned. The following particulars will enable the reader to inſtitute a compariſon.

	Feet.
The medium width of the ſurface - -	56
Do. of the bottom - - -	27
Depth on the average from ſea to ſea -	8
The fall of each of the 39 locks -	8
The breadth of each lock - -	20
The length of do. between the gates -	74

The contrivance for ſupplying the canal with water was alone a difficult and arduous undertaking. No leſs than ſix reſervoirs were found expedient; one near Kylſith covers a ſurface of 50 acres of land; another conſiſts of 70; and the whole occupy about 409, containing by meaſurement 12,679 lockfulls of water. The expence of the whole concern amounted to 300,000*l.* The toll for the whole line is 5*s.* 10*d.* per ton; againſt this is to be placed ſafety, time gained in paſſing from coaſt to coaſt; and the difference in inſurance, that uſually in time of war being in coaſting it from 15*l.* to 20*l*; and by the canal, 5*l.* Phillips's General Hiſtory of Inland Navigation, and Sinclair's General Statiſtical Account of Scotland.

FORTIFICATION, called alſo *Military Architecture*, is the art of fortifying or ſtrengthening a place, by making works around the ſame, to render it capable of being defended.

fended by a ſmall force, againſt the attacks of a more numerous enemy.

Some authors go back to the beginning of the world for the author and origin of military architecture. According to them, God himſelf was the firſt engineer; and paradiſe, or the garden of Eden, was the firſt fortreſs. Cain improved on the hint, in building the firſt city, Gen. iv. 17. After him came Nimrod, Gen. x. 10. Then Semiramis, as Poliænus relates, Stratagem. lib. viii. cap. 27. The Canaanites, Numb. xiii. 19. Deut. i. 28. David, 2 Sam. v. Solomon, 2 Chron. viii. 4. Rehoboam his ſon, 2 Chron. xi. 5. and the other kings of Judah and Iſrael; and at length the Greeks and Romans. Vitruvius, lib. x. cap. ult. and lib. i. cap. 5.

Such is the ſeries of thoſe who fortified places; to which might be added Pharaoh, the perſecutor of the Iſraelites, who built the cities of Pithom and Raamſes, Exod. i. 11.

In thoſe remote times, when the property of individuals was leſs valuable, or owing to the little progreſs made by mankind in the arts of deſpoliation, the only fences in uſe were ſuch as ſufficed to prevent the depredations of wild beaſts, and to prevent cattle from ſtraying among the few ſcattered patches of cultivation, or into thoſe immenſe wilderneſſes then unſubdued by the labour of man. At length the pleaſures of ſociety, added to the occaſional neceſſity for bartering with, or ſeeking the aid of neighbours, led mankind into cloſer compact, and ultimately to approximate ſo near as their ſeveral tempers or views might allow; and thus in time little hamlets and villages chequered the more open ſcites; theſe, again, accumulated ſo as to contain much property, and to excite among the more lawleſs a deſire to bereave them of whatever cattle, grain, &c. they might by their induſtry and frugality have amaſſed.

Hence aroſe that imperious neceſſity, which unfortunately for mankind has, notwithſtanding our boaſted civilization, been far from decreaſing. In times of yore, the conteſt was only between rival towns, and the fate of both was ſoon decided. Now we fight for kingdoms, while an inveterate hatred and jealouſy are handed down from one generation to another, like an heir-loom, founded on ſome paltry contention, or on ſome abſurd claim, in which the people at large are neither benefited nor even conſulted.

The means of defence naturally grew as the means of attack became more powerful; which, of courſe, they could not fail to do, in conſequence of the increaſe of faction, and of the intereſt taken by numbers in the cauſe of ſome plauſible pretender, or of ſome ambitious and daring adventurer. But it was not to be expected that the means of reſiſtance would be extended beyond what might be neceſſary to oppoſe the means of attack; therefore thoſe primary engines, the catapulta, the battering-ram, &c. were oppoſed by heavy maſſes of ſtone. The engineer confined himſelf to very ſmall projections, which, if we are correctly informed, in the firſt inſtance impended over certain parts of the wall, at various diſtances, like modern balcony-windows; theſe were gradually augmented both in area and in depth, until they became what are now called *round-baſtions*.

It does not appear that any important change took place for many centuries, nor, indeed, until ſome time after the invention of gun-powder, when battering cannon formed a part of the aſſailants' means, and ſpeedily evinced how little reliance could be placed on thoſe walls, which had formerly defied the powers of the ſeveral engines then in uſe; nor was it until iron ſhots were ſubſtituted for thoſe of ſtone, that the efficiency of artillery was properly underſtood. That being eſtabliſhed, the whole ſyſtem of defence was neceſſarily made to conform to the counteracting of thoſe deſtructive engines which now were introduced as the ordinary means of attack. The ſword and buckler, the lance, dart, javelin, ſling, bow and arrow, &c. loſt their reputation, and, dwindling into inſignificance on the great ſcale, were reſerved for individual conteſt, or for the minor purpoſes of deſultory warfare. It now became indiſpenſable, that the circumvallations ſhould be ſtrengthened, and to conſtruct ſuch ſtupendous bulwarks as might not only oppoſe the newly deviſed miſſiles, but, at the ſame time, ſupport ſimilar means of deſtroying the invading army and its batteries. By the exterior addition of deep ditches, and various outworks, great difficulty and delay were oppoſed to the beſiegers; while flanks, cavaliers, and eſpecially mines, were added for the more effectual accompliſhment of their deſtruction.

The great outline was thus marked out, but it remained for the moderns to bring the ſyſtem to perfection; for we find, that although the fortifications of the fifteenth century diſplay obvious improvements upon the ancient conſtruction, the grand principles were little underſtood, and that the minutiæ of this now important ſcience remained, until within a very few years paſt, moſt wretchedly defective. Men of genius, profiting by that experience which upheld the errors of engineers then conſidered ſkilful, at length remedied in part the defects of the old ſchool, and led the way to that exactneſs of proportion, and to that ſyſtematic arrangement, which characterize the works of our time.

We are not to conclude that this ſcience is confined merely to drawing out ſuch defences as ſhould ſuffice to prevent, or at leaſt ſo to retard the neceſſity for a ſurrender, as to coerce the beſiegers to evacuate their trenches; the immenſe armies now conſtantly brought into the field, and the heavy trains of artillery by which they are ever attended, occaſion not only an adequate preparation for reſiſtance, but the neceſſity for eſtabliſhing lines of communication of depots, &c. all of which muſt be on the beſt conſtruction for defence, containing ſafe lodgment for a ſufficient garriſon, together with ample and ſecure magazines for ſtores and proviſions. Conſequently, the engineers muſt poſſeſs great readineſs of computation, of diſcernment, and of appropriate reſource and application.

Without all theſe qualities the moſt ſcientific officer may fall into diſrepute; for, however valuable a perfect acquaintance with the theory may appear, yet the merely planning in the cloſet, and the laying down on a large plain ſuch lines of defence as may appear, in ſuch a ſituation, totally incapable of defeat, ſo far as may relate to mutual ſupport, and the great work of procraſtination, will be of no avail, if the other eſſentials which depend wholly on judgment and experience be wanting; the whole may be rendered abortive, and become contemptible, merely from a want of appropriateneſs in point of locality.

The period, in which the modern practice of military architecture may be ſuppoſed to have taken its riſe, was that in which the old circular towers were firſt converted into baſtions, about the year 1500. See BASTIONS.

The firſt authors who have written of fortification, conſidered as a particular formed art, are Latreille, Alghiſi, Marchi, Paſino, Ramelli, Cataneo, and Speckle, who, as Mr. Robins ſays, was one of the greateſt geniuſes that has applied to this art. He was architect of the city of Straſburgh, and died in the year 1589. He publiſhed a treatiſe of fortification in German, which was reprinted at Leipſic in 1736. Robins's Math. Tracts, vol. i. preface, p. 9.

After them Errard, engineer to Henry the Great of France;

France; Stevinus, engineer to the prince of Orange; Marolois, the chevalier de Ville, Lorini, Coehorn, the count de Pagan, and the marſhal de Vauban; which laſt two noble authors have contributed greatly to the perfection of the art. To whom we may add Scheiter, Mallet, Belidor, Blondel, Muller, &c.

Under the head of CONSTRUCTION, *Military*, we have entered at length on the ſeveral proportions of fortifications conſidered in its ſeveral claſſifications, and have ſhewn the ſeveral component parts, as formed and ſituated according to the ſyſtems adopted by the moſt celebrated engineers; therefore we abſtain from giving, in this place, any detail of their ſeveral principles; confining ourſelves to whatever may appertain to the ſcience in a general point of view.

FORTIFICATION, *the art of*, may be diſtinguiſhed into two parts, *viz.* the *elementary*, or *theoretical*, and *practical*.

Elementary, or *theoretical*, fortification conſiſts in tracing the plans and profiles of a fortification on paper, with ſcales and compaſſes; and in examining the ſyſtems propoſed by different authors, in order to diſcover their advantages and diſadvantages: whereas *practical* fortification conſiſts in forming a project of a fortification, according to the nature of the ground, and other neceſſary circumſtances, tracing it on the ground, and executing the project, together with all the military buildings, ſuch as magazines, ſtore-houſes, bridges, &c.

Fortification again is either *offenſive* or *defenſive*. *Offenſive* fortification is the ſame with the attack of a place, and is the art of making and conducting all the different works in a ſiege, in order to gain poſſeſſion of the place. See ATTACK and SIEGE.

Fortification, *defenſive*, or *Defence*, is the art of defending a town that is beſieged, with all the advantages which the fortification of it will admit. See DEFENCE.

Fortification is generally divided into two diſtinct branches, *viz.* natural and artificial; and again into regular and irregular. In natural fortification but little is required of the engineer; the defences offered by ſituations nearly inacceſſible rendering the aid of art ſometimes ſuperfluous, or nearly ſo; therefore, in ſuch inſtances but few additions are needful, and thoſe chiefly with the intention of preventing a *coup de main*. For want of ſuch a precaution, many important poſts have been ſuddenly and eaſily taken, which no army, however numerous and well provided, could have forced, unleſs indeed by ſtarvation, into capitulation. It would be impoſſible to afford any inſtruction regarding the works neceſſary in this branch of defence, ſince every thing muſt depend on local circumſtances, in the proper adaptation of which the engineer has the moſt favourable ſcope for a diſplay of talent.

This applies equally to offenſive and to defenſive conſtruction; the former applying chiefly to the various works uſed in attacks and ſieges, and the latter to the more general purpoſes of defending towns, forming depots, commanding, or poſſeſſing particular ſituations, ſcouring thoſe parts which admit of approach, protecting or covering harbours, &c. and, in general, more tending to ſelf-preſervation, and to controul, than aiming to annoy others, or to the acquiſition of dominion. When works are built in a ſolid manner, ſuch as ſhould laſt for many years, they are called permanent: of this claſs are all citadels, fortreſſes, commanding redoubts, and block-houſes, &c. When raiſed only for any particular purpoſe, after the completion of which they are either deſtroyed or abandoned, they are ſaid to be temporary: of this kind are all entrenchments made for covering of the flanks, &c. of armies while in the field; the trenches opened by beſiegers, with all their ſupporting or cautionary lines; batteries made on emergency; together with all, under whatever term they may be denominated, which have only a periodical utility.

With reſpect to whatever relates to regular fortifications, we have already, under CONSTRUCTION, *Military*, diſplayed not only the ſyſtems moſt generally approved, but their good and bad qualities, for the expoſition of which we are indebted to gentlemen whoſe profeſſional ſkill is too pre-eminent to be dependent on our applauſe. There the principles laid down by that great maſter of the ſcience, Errard, together with the ſeveral variations adopted by Vauban, Blondel, count Pagan, Bombelle, the Chevalier de Ville, Sardi, Coehorn, Belidor; the marquis de Montalembert, &c. &c. may all be ſeen both abſtractedly, and contraſted in the moſt perſpicuous manner. In the ſame place we have furniſhed a complete detail of the ſeveral features of regular fortification, and explained their ſeveral intentions. It is here proper to remark, that fortifications can be conſidered regular only when the encloſed area is of ſuch a form, whether a triangle, a ſquare, a circle, an elliplis, as may be inſcribed in a regular manner according to geometrical operations.

It is uſual, indeed indiſpenſable, to divide the great ſurrounding line, or circumference, into as many faces, or portions, as may be beſt adapted to the conſtruction of ſuitable defences according to one or other of the three ſyſtems; namely, great, mean, and little. The number and extent of theſe faces muſt be regulated as well by the extent, as by the form of the area to be incloſed. Small circles may be divided into five or ſix faces; moderately extenſive ovals may have ſix alſo; while both circles and ovals of greater range will demand one or more additional faces; in order to reduce the exterior lines of defence within ſuch bounds as may duly proportion the faces and flanks in every part, and keep the angles within juſt limits.

Whatever may be the arrangement, it muſt ever be attended to, as a fundamental axiom, that every part may be defended by ſome other ſtanding within the ordinary point-blank range of a muſket. Whenever this point is overlooked, the defences will be proportionably weakened, according to the undue prolongation of the faces, the abſence of protecting flanks, and the conſequent deficiency of mutual ſupport.

Taken in the aggregate, a fortification ſhould not be deemed "irregular," merely becauſe the ſeveral faces may be in ſome degree diſſimilar, provided each face be in itſelf regular, and that the junctions of the ſeveral faces of the connecting baſtions be ſeverally effected in a regular manner. But this can reſult only from a great attention to conſtruction, and can never take place where the figures or their proportions are heterogeneous; ſuch as half a ſquare, and half a pentagon: whereas the half of a ſquare may be united with the half of a hexagon, or any figure whoſe multiple is 2. So may half a pentagon be united with half an enneagon, (or figure of nine ſides) though they have no common multiple, becauſe in each there would be half a baſtion, and half a curtain for their reſpective terminations, which could of courſe be eaſily blended.

Let us ſuppoſe that the circumference of an area be elliptic; the two more circular parts, namely, thoſe ſtanding at the extremities of the conjugate diameter, may be fortified according to that ſyſtem their radius may ſuggeſt, ſay according to the mean ſyſtem, while the two long ſides, being each ſegments of larger circles, will probably require to be divided each into two faces, all of which will be moſt appropriate to the great ſyſtem. One end may have a horn-work, the other a crown-work, and the ſeveral faces of the

two

two long ſides may have each a raveline, with, or without lunettes, tenaillons, counter-guards, bonnets, fleches, &c. yet the whole may bear ſufficient types of regularity to allow its coming under that deſignation; the rules neceſſary for the due combination of a regular and perfect ſyſtem of defence, as founded on approved ſyſtems, being, in every inſtance, obſerved.

The figure, and the number of faces into which it is to be portioned off, being determined upon, it then becomes a queſtion whether the works are to be planned *outwards* or *inwards*. In the former caſe, the figure becomes the interior lines, and a great addition is made to the area, but the works will be far more extenſive, and require a more numerous garriſon than when the place is to be fortified *inwards*, whereby all the works are thrown within the figure, to the great diminution of the area, and conſequent reduction of the works, which may then be defended by about one-third the number of men required in the other mode.

The proper *defilement* of the ſeveral works, as relating to the body of the place, muſt ever be attended to. By this term we comprehend the ſpread, or arrangement, of the outworks in that ſubordinate manner progreſſively, whereby thoſe moſt remote are invariably under the command of thoſe nearer, from the main defences included in that line called the principal, which uſually conſiſts of alternate curtains and baſtions. Every outwork muſt defend, or prevent the approach to, ſome particular point; or it muſt occupy ſome ſpot which might alſo give advantage to the enemy. Whatever be its ſituation or intention, it ſhould be ſo conſtructed as never to ſerve as a ſecure lodgment when taken by the enemy, nor ſhould its face or its flanks preſent the means of attacking others of the defences. This precaution can be properly effected only by keeping the ramparts ſo low as to be commanded from every part of the interior, and by cauſing the flanks to be expoſed to ſome powerful flanking fire, whereby the enemy would be too ſeverely galled to admit of his retaining poſſeſſion. Further, the aſpect of every ſuch outwork ſhould be carefully averted from the poſſibility of making even a grazing fire upon other defences; to inſure which, the angle made therewith ought not to be leſs than 120 degrees, for proximate, and 150 degrees for more remote batteries.

In moſt fortifications, the garriſon and the ſtores, but eſpecially the ammunition, are lodged in ſecurely vaulted buildings, which, from their power to reſiſt the fall even of the largeſt ſhells, are deſignated "bomb proofs," that is, proof againſt bombs; many of the more retired parts of the body of the place, ſuch as the curtains, are vaulted in a ſuitable manner for the accommodation of the troops, and magazines for powder are built in various parts, ſo as to be ſufficiently near to the ſeveral works they are to ſupply. For the deſcription of *magazines*, we refer to that article.

The ramparts have rarely ſufficient *talus*, or ſlope, within, to admit of men aſcending directly from the terre plein of the interior; though in ſome looſe ſoil the angle is ſo great as to offer conſiderable facility in that reſpect; but it being neceſſary to provide means for the paſſage of heavy ordnance up and down, as well as to favour the eaſy and ready acceſs of troops to every part of the defences, long ſlopes, called "ramps," are made in various parts, but eſpecially within the ſeveral faliant angles; theſe ſhould be from eight to twelve feet wide, according to their ſituation and importance, and ought to be very firmly ſupported at their ſides, eſpecially if not made to lie along the inſide of the rampart. The aſcent, or elevation of a ramp, ſhould never exceed thirty degrees; but, where practicable, they are better under, than over, twenty degrees.

In every fortified place great attention ſhould be paid to the ready acceſs of troops from every quarter towards each ramp. This can be effected only by a proper diſtribution of the ſeveral ſtreets and avenues, and by keeping full thirty yards or more clear all around the interior. The houſes neareſt to the ſeveral works ſhould be allotted to the garriſon, or to ſuch volunteers, &c. as might be able, in caſe of a ſurprize, to man the works inſtantly; while thoſe parts neareſt to the magazines and principal defences ſhould be occupied by perſons appertaining to the artillery. Should an enemy even ſucceed in a *coup de main*, ſo far as to aſcend to the body of the place, they might, by ſuch an allotment, be driven from the ramparts; or if they ſhould deſcend into the interior, might be oppoſed by a formidable force collected from the houſes, overlooking the body of the works.

To favour the ſorties made by the garriſon for the purpoſe of ſtorming the trenches of the beſiegers, and of demoliſhing their batteries, magazines, &c. ſally-ports are made in various parts, generally concealed from the knowledge of all but a few, and carefully cloſed until ſuch time as a ſortie is about to take place. Counter-mines are made under the ſeveral defences, with the view to prevent the enemy from carrying their galleries under them; and mines, as well as ſmaller *fougaſſes*, are ſunk with the intention of blowing up ſuch outworks as, when poſſeſſed by the enemy, might prove obnoxious to the defendants.

In every fortified place, a ſufficient ſupply of good water is indiſpenſable. If conduits proceed from a river, lake, &c. they muſt be ſecured from the enemy's ſhot, and, where neceſſary, be amply defended by ſuitable works. Large ponds ſhould be made in every fortreſs where ſpace can be allowed, and in every outwork one or more wells of proper diameter, and ſecurely framed, or lined with maſonry ſhould be ſunk. In fact, the utmoſt attention ſhould be paid to the furniſhing every quarter abundantly, and to preſerving ſuch as may be carried off the tops of houſes &c., during falls of rain, by means of pipes leading to ciſterns concealed under ground.

Hiſtory furniſhes various moſt encouraging inſtances of the good effects reſulting from the fortitude of garriſons, weak in numbers, and even indifferently ſupplied. We need look no farther back than to the glorious defence made by the unfortunate city of Saragoſſa; and to the wonderful obſtinacy with which the brave inhabitants, both male and female, of Gerona, contended againſt a very ſuperior and highly diſciplined army. The chances of war are greatly in favour of any garriſon under fair circumſtances; if it be ſtrong and well appointed, it may make ſo many ſorties, as to harraſs the beſiegers greatly; and eventually may be ſo ſucceſsful as to cut off large portions from time to time; ſo that when added to thoſe diſeaſes ever attendant upon fixed camps, the enemy may be unable to continue the ſiege. Few ſituations admit of a blockade, which can rarely be attempted by any army not very far ſurpaſſing the garriſon in numbers; therefore occaſional ſupplies and reinforcements may be generally expected. Conſidering alſo the immenſe loſſes to which the aſſailants are ſubject when their approaches are puſhed near to the body of the place, and the uncertainty attendant upon the attempt to force a paſſage through any breach that may be made, it ſhould appear that much remains in the power of an orderly and brave garriſon, even after ſuch advantages may have been gained by the beſiegers, as ſhould lead to the opinion of their being ſoon in poſſeſſion of the place. What with cutting off diſmantled works, filling the breach with burning faggots, cotton ſteeped in oil, &c. mining, traverſes, ſhowers of grenades, and of grape-ſhot, it is evident that the aſſailants may have to overcome the moſt formidable obſtacles, and

after all be obliged to allow the garriſon, to retreat by ſome oppoſite outlet, leaving them in poſſeſſion of a ruined fortreſs! If the retreat be made to a good citadel, the advantage gained may be purely nominal; and the beſiegers may be happy to relinquiſh thoſe defences, to gain which ſo much time, treaſure, and blood were expended.

Field-fortification is generally of a temporary nature, and abounds with variety; no two ſituations being exactly ſimilar. Here the engineer has a noble opportunity for the diſplay of ſkill. It often happens that a ſmall, or inferior army is compelled to chooſe, and that too without much delay, ſome ground affording natural advantages, whereon to entrench and to make a ſtand. No time is left for deep reſearch, for conſultation, for ſubſtitution, or for the correction of errors. In ſuch caſe the weak points muſt be firſt attended to, and ſecured ſo far as circumſtances may permit; after which the ſtronger poſitions muſt be amply fortified, and rendered both compact in themſelves, and aids to the weaker poſts. By theſe means a very powerful line of defence may be eſtabliſhed, care being taken to place the artillery in thoſe places moſt conducive to their full effect, and in particular guarding the moſt acceſſible parts in ſuch manner as ſhould deter the enemy from approaching. In ſome inſtances it is expedient to allure towards ſome point apparently weak, and, when it is attacked, to open various maſked batteries ſuddenly on the flanks of the aſſailants. This never fails to diſcourage, and at all events creates much doubt, while it eſtabliſhes the reputation of the defenders, and cauſes them to be treated with much diffidence and reſpect.

The following practical maxims, regarding the conſtruction of field works, may prove acceptable.

1. The ſpot on which the works are to be conſtructed ſhould determine their figure; no ſacrifice of ſtrength ſhould be made in order to preſerve any regular form, that diſpoſition being the beſt which occupies the ground to the greateſt advantage.

2. All ſlopes, and approaches of every deſcription, ſhould be ſubjected to the direct fire of the defenders; obſerving that the ſmall arms being in ſuch caſes of material ſervice, the ſeveral flanking parts ſhould never exceed the diſtance of two hundred yards, but that, if poſſible, the whole of the ſurrounding country, for five hundred yards at leaſt, ſhould be diſcoverable, and open to the fire from the works.

3. Works that are intended for the defence of a defile, ſhould always be within muſket ſhot (*i. e.* 200 yards), ſo that if taken by the enemy, they may to him be equally untenable.

4. In flanking-defences, thoſe which ſtand at right angles are preferable, becauſe the fire from one face is always parallel to the other face, and muſt, of courſe, take the aſſailants in flank by a direct fire thereon: a matter known to be of ſingular importance, eſpecially where new levies man the works; it being extremely difficult to enforce a proper attention to taking a cool and deliberate aim.

5. If a ſaliant-angle is leſs than 60 degrees, it will expoſe its faces to be enfiladed by an enemy ſituated nearly in the line of its capital, and it will beſides be weak in many reſpects; beſides preventing the other defences from projecting in a proper manner, leſt they ſhould become ſubject to its operations, if the raveline, redan, &c. it compoſes, ſhould fall into the hands of the enemy.

6. On the other hand, re-entering angles ſhould never be greater than 120 degrees; becauſe that is the utmoſt ſcope that can poſſibly be allowed for the direction of even muſketry, when ſerving as a flanking-fire. Cannon can rarely graze upon the adjacent battery or flank, when the re-entering angle exceeds 105 degrees; the declination of the embraſures not allowing more than from 10 to 12 degrees of lateral inclination.

7. Always make the entrance to a redoubt, or other work of that nature, ſomewhere in its rear, or in whatever part may be leaſt expoſed; taking eſpecial care ſo to cover the entrance by traverſes, either plain, curved, or angular, ſuch as may expoſe the enemy, ſhould he attempt to force an entrance, to a galling fire, as well as to ſhowers of grenades, ſtones, or any other mode of annoyance. Where practicable, every entrance ſhould have a draw-bridge, or at leaſt a *chevaux de frize*; or, for want of them, an *abbatis* made of trees, of which the branches have been lopped to points outwardly arranged, may prove an excellent defence.

8. Where the entrance muſt be made ſomewhere in the front, it ſhould be in ſome re-entering angle, and always in a curved or angular direction, ſo as to prevent cannon-ſhots from ſcouring the path-way. This may alſo be prevented by throwing ſeveral traverſes acroſs; cauſing all who enter to paſs round their ends by means of indentations in the lateral wall, or paliſades: but this latter mode is ill ſuited to the paſſage of guns, and is moſt applicable to *caponnieres* leading from bonnets, fleches, and other ſuch out-works that are chiefly intended as poſts for muſketry only, and which may be manned only on particular occaſions.

9. All troops or batteries acting within narrow limits, which gradually extend in front, are ſubject to the inconvenience of preſenting a leſs front than the enemy can ſhew in oppoſition thereto. It therefore requires much caution and judgment, when taking poſt, with a view to ſelf-defence, not to become expoſed to ſuch diſproportionate powers. It is ſometimes better to retreat altogether into a paſs, fortifying the entrance internally, than to cover it exteriorly. Every thing muſt depend on circumſtances; but there ſhould be no means omitted to prevent the enemy from coming round on the flanks, as they will aſſuredly do, if localities may permit.

10. A poſition commanded, eſpecially by muſketry, from any eminence in front, flank, or rear, muſt, generally ſpeaking, prove untenable. Where the opening for ſuch command is very confined, it may perhaps be cut off by epaulements, raiſed to a ſuitable height, ſo far as to obſtruct any plonging fire; but the *ricochet* fire can only be prevented by ſuch a number of traverſes as may effectually cover the interior. Hence nothing ſhort of peremptory neceſſity ſhould induce to taking up ſuch a poſition. Obſerve, that of all fires, that upon a flank, which is called "enfilading," is the moſt deſtructive.

11. No reliance can be placed on a poſt, of which the rear is ſubject to attack. If, notwithſtanding every precaution, this liability may exiſt, the beſt chance is to keep a good look out; and in caſe the enemy ſhould attempt an attack in that quarter, to abandon the poſt, and either to charge him in front while his force is divided, or to allow his penetrating far enough in the rear to be attacked with effect, either by the whole, or by ſuch a detachment of the garriſon as circumſtances may dictate. It is ſcarcely ever practicable to fortify againſt both front and rear, without dividing the defenders in ſuch manner as muſt weaken, and ſubject the party to deſtruction. A redoubt well conſtructed, or a well choſen ſpot, open on all ſides, will, in ſuch caſe, be preferable to any lines badly covered in their rear.

12. In drawing out lines of defence, &c. make the faces directly towards thoſe parts moſt ſubject to attack; keeping the angles (eſpecially the ſaliant) out of thoſe directions that may ſubject them either to aſſault, or to be enfiladed.

13. Knowing

13. Knowing the ſtrength of your force, take care to proportion your defences accordingly: give from ſix to eight paces, or ſay twenty feet at the moſt, for every piece of ordnance; and for every firelock allow two feet. If there ſhould be no cannon to provide for, one foot only ought to be allowed for each firelock; obſerving that the infantry are always ſuppoſed to be drawn up two deep: thoſe on the *banquette* never to fire until thoſe on the *terre plein* may have loaded, except on emergency.

14. In the above computation, always caſt out a ſixth part of your force, both artillery and muſketry, to be in reſerve: the former to replace any that may be damaged; the latter to aid wherever the garriſon may be hard preſſed, as well as to fill up vacancies.

15. The interior of a work ſhould never be ſo crowded as to debar the garriſon from moving freely, and eſpecially from lying down. It is uſual to compute that each piece of artillery, with its appurtenances, and the men employed to work it, will occupy about 220 ſquare feet. This relates to field pieces; but heavy ordnance will demand full half as much more. For every muſket a ſpace of 18 feet ſhould be allowed; but in this much muſt depend on climate. Where extreme heats are prevalent, double that area will be indiſpenſable; while, in very cold ſituations, much leſs may ſuffice. Interior ſpace is, however, always deſirable, provided the defences be not thereby ſo extended as to render the garriſon unequal to their maintenance.

16. The ſubſtance of parapets for field-works muſt depend both on the weight of metal oppoſed to, and mounted on, them; the ſoil will alſo occaſion much variety; but, if moderately firm, it ſhould be at leaſt 12 feet in thickneſs; but 15 will, in moſt caſes, be better. Thoſe intended to reſiſt muſketry only need ſeldom exceed 8 feet: in many caſes, eſpecially where found clay can be obtained, leſs may ſuffice. The height muſt conform to local circumſtances; obſerving that the *banquette* ſhould always be raiſed to $4\frac{1}{2}$ of the creſt, otherwiſe men of ordinary height could not level over in a proper manner.

17. Works made on the borders of ravines muſt be ſo conſtructed as to have full command down to the bottom of every part, and eſpecially of all deſcents to them from the oppoſite ſide. Such may be very eaſily covered; but where that advantage does not exiſt, the ditch muſt be made as wide and as deep as may ſuffice at leaſt to ſupply ſoil for the ramparts and parapets. No batteries can be better than thoſe excavated from maſſes of rock, or obdurate tough ſoil, inacceſſible towards the front. But ſuch are rarely reſorted to in this branch of fortification. Mounds of earth may either be cut through for embraſures, ſo as to cover the cannon; or they may be ſcarped both within and without in ſuch manner as to prove admirable lines, mounting the cannon *en barbet*. If a wide range towards the flanks is requiſite, this latter mode is highly appropriate.

18. In the conſtruction of *tetes de pont*, always ſelect a re-entering angle, where ſuch can be found properly ſituated. This will prevent the enemy from commanding the flanks and rear; as he inevitably would, if the works were conſtructed upon a ſaliant angle of the ſtream. Beſides, in the former mode, the defenders may line the oppoſite banks, on both ſides of the bridge, with additional defences, that would act on the flanks of thoſe advancing to the attack, as well as when abſolutely croſſing upon the bridge, which might of courſe be deſtroyed by the fire of heavy artillery.

19. Four magazines ſhould be ſo divided along your works, as to afford a ready ſupply to every part; yet ſhould each be ſo far removed as to prevent material injury to the defences, in caſe of exploſion. If duly ſunk, and covered by epaulements, and by an adequate load of ſoil ſupported on faſcines, &c. reſting on good props, they will be in little danger even from the heavieſt ſhots thrown by cannon; but it will not be eaſy to give them ſtrength enough to reſiſt the fall of a heavy ſhell. The apertures of all magazines ſhould face towards that quarter leaſt expoſed to the enemy's fire.

For the minor parts of conſtruction, we refer our readers to the articles FASCINE, GABION, BATTERY, &c. where the ſeveral proportions and uſes of each will be found detailed. To conclude this ſubject, we ſhall briefly obſerve, that the ſame general principles, which govern in the conſtruction of *permanent* fortifications, apply, ſo far as circumſtances may admit, to the projection and to the raiſing of *field-works* in general. The mutual ſupport of contiguous parts muſt ever be the principal conſideration.

FORTIFICATION is alſo uſed for the place fortified: or the ſeveral works raiſed to defend and flank it, and keep off the enemy.

All fortifications conſiſt of lines and angles, which have various names, according to their various offices.

The principal angles are thoſe of the centre, the flanking angle, flanked angle, angle of the epaule, &c.

The principal lines are thoſe of *circumvallation*, of *contravallation*, of the capital, &c. See each in its place.

Fortifications are divided into *regular* and *irregular*, and again into *durable* and *temporary*. *Regular* fortification is that wherein the baſtions are all equal; or that which is built in a regular polygon, the ſides and angles whereof are generally about a muſket-ſhot from each other.

In a regular fortification, the parts being all equal, have the advantage of being equally defenſible; ſo that there are no weak places. *Irregular* fortification is that wherein the baſtions are unequal, and unlike; or the ſides and angles not all equal, and equidiſtant.

In an irregular fortification, the defence and ſtrength being unequal, there is a neceſſity for reducing the irregular figure, as near as may be, to a regular one; *i. e.* inſtead of inſcribing it in a circle, it ſhould be inſcribed in an oval, ſo that one half may be ſimilar and equal to the other half.

And as the irregularity of a figure depends on the quantity of angles and ſides; the irregularity of a fortification ariſes either from the angles being too ſmall, or the ſides being too long, or too ſhort.

Conſequently an irregular figure being propoſed to be fortified; all the angles, with the quantity of the ſides, muſt be found, to be able to judge how it is to be formed. See *Plate* V. *Fortification*, *fig.* 1. which repreſents a fortification inſcribed in an oval.

In this caſe the ſides C D, G H, on the flat parts, are ſtronger than the ſides A B, E F, on the narrow parts, ſuppoſing all the exterior ſides equal, and the place equally fortified. When the angles B C D, C D E, of the polygon are very great, and the beſieger comes within a ſmall diſtance of the works, he cannot approach nearer, without being ſeen in front, except by a direct ſap, with traverſes; and as this way of approaching preſents but a ſmall front, the beſieged, who have a much larger, may oppoſe with peculiar advantage: whereas, if the angles H A B, A B C, of the polygon, are very ſmall, the beſiegers carry their approaches to the counterſcarp itſelf, and have always a larger front than the beſieged; and, as the beſiegers muſt extend their approaches to three fronts, whether they are ſmall or large, the work of the approaches before the front B C D E will be to the work before the front H A B C, as the line B E is to the line H C, nearly, *i. e.* as the greater

axis of the oval is to the leſs; and therefore the front C D, on the flat ſide, is ſtronger than the front A B, on the narrow ſide; conſequently, the longer C D is, ſo that the lines of defence are within the reach of muſket-ſhot, and the angles B C D, C D E, are the ſame, the ſtronger will the front be; ſince the works become more ſpacious, hold more troops to defend them, and the beſiegers are obliged to extend their trenches farther. Moreover, the greater the angles of the polygons B C D, C D E, are, the exterior ſides being the ſame, the ſtronger will be the front C D; becauſe the length of the line B E increaſes, and the extent of the beſiegers approaches in proportion; and, therefore, the ſtrength of a fortification increaſes in proportion to the number and length of its ſides; ſo that a dodecagon is ſtronger than an octagon, when the length of their ſides is the ſame. However, as it is found difficult to inſcribe a polygon in an ellipſe or oval, the following more eaſy method will anſwer the purpoſe. Reduce the ſpot of ground to be fortified to the figure A C E G (*fig.* 2.) and draw B E, A F, parallel to each other; draw C H, D G, perpendicular to theſe lines, and at equal diſtance from the points B and E, and let their interval be equal to that of the lines B E and A F: then draw D C, G H, parallel to A F and B E, and equally diſtant from them; and from their interſections C, D, G, H, with D G, C H, as centres, deſcribe arcs, with a radius equal to C D or G H, ſo as to interſect the lines A F, B E, in A, B, E, F; join the points A, B, E, F, and A B C D E F G H will be an oblong octagon, having one half ſimilar and equal to the other half. If a hexagon be to be deſcribed, inſtead of drawing the two lines C H, D G, one will be ſufficient; in a decagon there muſt be three, and four in a dodecagon. If the ſides cannot eaſily be made equal, then the ſides A B, E F, on the narroweſt part of the polygon, ſhould be the longeſt, becauſe it is the weakeſt. But when the figure cannot in any reſpect be made regular, the ſtrength of each ſide muſt be eſtimated according to the works a beſieger is obliged to make in the attack, and according to the obſtacles he meets with in his approaches. Muller's Elements of Fort. p. 146, &c.

Durable fortification is that built with deſign to remain a ſtanding ſhelter for ages. Such are the uſual fortifications of cities, frontier places, &c.

Temporary fortification is that erected on ſome emergent occaſion, and only for a little time.

Such are field-works, caſt up for the ſeizing and maintaining a poſt, or paſſage; thoſe about camps, &c. as circumvallations, contravallations, redoubts, trenches, batteries, &c. See each article.

FORTIFICATION, *Marine*, is ſometimes uſed by way of diſtinction from *land* fortification. and denotes the art of raiſing works fit for the defence of a harbour againſt the attacks of any kind of ſhipping; but the works proper for this purpoſe depend in a great meaſure on the principles employed in the fortification of towns. However, attention ſhould be given to the ſituation of roads or harbours in contriving works for their defence: *e. gr.* when a town lies open to the ſea, on a curved, or ſtraight bold ſhore, and has before it a ſufficient depth of water and good anchorage, the ſhips, in this ſituation, may be well defended by forts built near the water's edge on each ſide of the anchoring place, ſo contrived as to have two or three batteries, one higher than the other, and furniſhed with a ſufficient number of cannon, carrying ſhot from twenty-four to forty-eight pounds. A town, in this ſituation, may be defended by a rampart, or wall, well flanked, built along the ſhore, beſide the fortifications on the land ſide. The works along the ſhore ſhould be carried ſo near to the water's edge, that troops, attempting to land under the cannon of a fleet, might not find ground on which to intrench themſelves. Farther, when a harbour, being a bay, has a ſhoal or ſmall iſland lying before its entrance, a ſtrong fort ſhould be built upon the iſland, in a place where it can command the entrance on both ſides, if the iſland be not too large; otherwiſe two or more forts ſhould be erected in ſuch places as may command the avenues to the bay; other forts ſhould alſo be raiſed on the moſt convenient points of land, forming the mouth of the bay. Again, when the harbour is in a bay, whoſe points, forming the entrance, ſtretch into the ſea, and approach one another within cannon ſhot; ſuch a harbour may be fortified by building on both ſides of its entrance one or more forts; and, if poſſible, a fort ſhould alſo be built within the harbour's mouth in ſuch a manner, that its cannon can rake the ſhipping fore and aft as they come in.

When a harbour is formed by a cluſter of iſlands, it is eaſily fortified, if the channel between the iſlands is not too wide for the command of cannon from one or both ſhores; but if it be too wide, the ſhipping that rides there muſt be defended from the batteries on the ſhore. When the harbour lies in an inlet, or river, ſome miles above its mouth, a fort built at each point of the entrance, when the paſſage lies ſtraight, and can be commanded from ſide to ſide, and two others between them and the harbour, but not directly oppoſite, unleſs the breadth of the channel requires it, will be a proper ſecurity for the ſhipping in ſuch a harbour; and if the channel or river is winding, the forts ſhould be built where they can command a reach at leaſt, or be ſo placed at the bends, as to command two adjacent reaches. See FORTS, and Robertſon's Treat. of Marine Fort. part ii. § 2. For the fortification of harbours by booms, ſee BOOM.

FORTIFICATION, *Profile of a*, is a repreſentation of a vertical ſection of a work, ſerving to ſhew thoſe dimenſions which cannot be repreſented in plans, and are neceſſary in the building of a fortification. This profile is conſtructed in the following manner: provide a ſcale of equal parts, adapted to the perpendicular height of the work, *e. gr.* let *a b*, *Plate* V. *fig.* 3. be a ſcale of twenty toiſes; and let A B repreſent the level of the ground plane, ſo that thoſe parts of the fortification which are above the ſurface of the ground, or below it, may be above or below this line in the profile. From the point A, in the line A B, take A C = four toiſes three feet, for the interior talus or ſlope of the rampart; at C erect a perpendicular C D of three toiſes eighteen feet for the height of the rampart; through the point D draw an indefinite line D N parallel to A B, in which take D E = 5 toiſes for the breadth of the terre-plein of the rampart; at the point E erect the perpendicular E F = 2 feet from the height of the banquette, and draw F H parallel to D N, making F G and G H each equal to three feet. Draw the line E G, which will repreſent the talus of the banquette, and G H will be the upper part of it; on the point H erect the perpendicular H I = $4\frac{1}{2}$ feet from the height of the parapet above the banquette. From I, draw the indefinite line I K parallel to D N, in which take I L = $1\frac{1}{2}$ foot, and draw H L which will be the interior ſide of the parapet: take L K = 3 toiſes for the thickneſs of the parapet, and from the point K let fall the indefinite line K P, perpendicular to the line A B, and produce it below A B: in this line take K M = $2\frac{1}{2}$ feet, and draw the line L M for the upper part of the parapet, which is a talus, that the ſoldier on the banquette may be able to diſcover the covert-

way

way and the glacis. On the point N, where D N interſects K P, as a centre, with a radius of one foot, deſcribe a ſmall ſemi-circle, which repreſents the cordon; take N P = 6 toiſes, and from the point P draw an indefinite line P n parallel to A B, which will repreſent the bottom of the ditch, the depth of which is ſuppoſed to be equal to the height of the rampart. Take N O = 5 feet for the thickneſs of the revetement of the cordon, and from the point O draw the indefinite line O Q parallel to N P; this will be the interior ſide of the revetement of the point P, where the line P n meets the line N P; take P R = 7 feet, or about the fifth part of its height N P, for the talus of the revetement, and draw the line N R, which repreſents the ſcarp or exterior ſide of the revetement: take R S = 1 foot for the jutting of the foundation, and draw S T perpendicular to P n, making it equal to two or three toiſes from the depth of the foundation; draw T Q parallel to P n, and let it interſect O Q in Q; and let Y & be drawn parallel to N M, and at the diſtance of three feet for the revetement of the parapet. In order to repreſent the profile of the counterfort or buttreſs, when there is any, take O V = 9 feet, and draw V X parallel to O Q; V X, Q O, will repreſent this profile, by means of which the revetement O R is ſtrengthened. That the terre-plein of the rampart may have a proper declivity for carrying away the water which falls upon it, let D W be equal to 1 $\frac{1}{2}$ foot, and draw W E, which will repreſent the upper part of the rampart, and the line A W repreſents the ſlope of its interior ſide. Suppoſe the breadth of the ditch to be twenty toiſes, and lay this down from P to n; and on the point n erect the perpendicular n m, terminated by the line A B at m, which will be the limit of the conterſcarp. At the diſtance of three feet from this line, and parallel to it, draw z y, which will give the thickneſs of the revetement of the conterſcarp; n u = 3 feet will be the talus of this revetement, and the line u m the exterior ſide of it. The foundation may be made to terminate at the diſtance of about ſix inches from the point u. Let m c = 5 toiſes be the breadth of the covert-way, and at the point c erect a perpendicular c d = 2 feet for the height of the banquette. Draw d f parallel to A B, and equal to one toiſe, in which take d e and e f each equal to three feet.

Draw the line c e for the talus of the banquette, and e f will be the upper part of it: from the point f erect a perpendicular f l = 4 $\frac{1}{2}$ feet, for the height of the parapet of the covert-way above the banquette. Produce f l till it cuts A B in r; take r g = 20 toiſes from the breadth of the glacis, and draw l g, which will repreſent the glacis, or the declivity of the rampart of the covert-way: in this line take l h = 1 foot, and draw h f, which will be the interior ſide of the parapet of the covert way; after which let there be a paliſade conſtructed on the banquette, and the profile is finiſhed. Encyclop.

FORTIFIED Place, a *fortreſs*, or *fortification*, *i. e.* a place well flanked and ſheltered with works. See *Plate* V. *Fortification*, *fig.* 4. with the explanation annexed to it, and *fig.* 5. which repreſents a fortified place beſieged.

Places fortified after the modern way conſiſt chiefly of baſtions and curtains, and ſometimes of demi-baſtions, according to the ſituation of the ground: of cavaliers, ramparts, fauſſe-brayes, ditches, counterſcarps, covert-ways, half-moons, ravelines, horn-works, crown-works, out-works, eſplanades, redents, and tenailles. See each under its proper article, Bastion, &c.

There are other moveable and additional parts; as bermes, parapets, banquettes, embraſures, cordons, boyaux, moulinets, chevaux de friſe, chauſſetrapes, galleries, mantelets, batteries, ſaps, mines, blinds, gabions, and paliſades. See each in its place, Berme, Parapet, &c.

Several of theſe works, again, conſiſt of diverſe parts, which have different denominations: thus, a baſtion conſiſts of faces, flanks, caſemates, orillons, gorge, &c. which ſee. See Fort, Fortress, Fortification, and *Military* Construction.

Fortified *Iſland*, in *Geography*, an iſland in the Indian ſea, about a mile in circumference, ſtony by nature, and fortified by art at a very great expence; the only landing-place being at the gate way, which is defended by ſtrong works: about a mile from the coaſt of Malabar, oppoſite to Onore. N. lat. 14° 15′. E. long. 74° 4′.

FORTIGUERRA, Nicholas, in *Biography*, an Italian poet and churchman, was deſcended from an ancient family, and born about the year 1674. Little is known of his early life, but he was advanced to a biſhopric by Clement XI. He ſeems to have ſet his heart upon a cardinal's hat from Clement XII. It was, however, delayed ſo long, that Fortiguerra fell into a lingering illneſs through chagrin and diſappointment, which carried him off, in 1735, at the age of ſixty-one. As an author, he is principally known by a burleſque poem, entitled "Ricciardetto," written in defence of the ſuperiority of Taſſo over Arioſto. The poem is in eaſy verſe: the compoſition was pleaſant, but fanciful. It was firſt publiſhed in 1738 in 4to., and afterwards at Paris, in 3 vols. 12mo. He publiſhed a tranſlation in verſe of the comedies of Terence, printed in 1736, with the Latin text.

FORTIN, or Fortlet, a diminutive of the word *fort*, importing a little fort, or ſconce, called alſo field fort.

Fortin, *Star*, is that whoſe ſides flank each other, &c. See *Star* Fort.

FORTIORI. *A multo Fortiori*. See Multo.

FORTIS Aqua. See Aqua *Fortis*.

FORTISSIMO, Ital., in *Muſic*; the ſuperlative degree of *forte*, implies very loud. The comparative degree of *forte* is *più forte*, more loud.

FORTITUDE, in *Moral Philoſophy*, is one of thoſe virtues which have been long diſtinguiſhed by the appellation of cardinal virtues; the other three being prudence, juſtice, and temperance. To fortitude, indeed, the name of virtue has been particularly appropriated, not only by profane authors, but alſo in the ſacred writings. (See 2 Pet. i. 5.) Nor is this appellation miſapplied, if we conſider that the mind muſt be prepared by this virtue to acquire, and alſo to maintain the reſt. True fortitude ſhould be diſcriminated from that mechanical courage, or natural intrepidity and daringneſs, which is often exhibited by thoſe who have a great deal of fire in their conſtitutions. Accordingly we may define it to be, ſuch a firmneſs and reſolution of ſpirit, inſpired by a ſenſe of what is juſt and honourable, as amidſt all the dangers and evils incident to human life, enables a man ſteadily to purſue the dictates of conſcience and prudence. The *ſeat* of this virtue is the ſoul; whence it follows, that brawny limbs, a firm conſtitution, and fermented blood, are not the qualities which conſtitute a hero. The vigour of nature may be a good foundation for courage; but this is a quality of the mind, and conſiſts particularly in the reſolution of the will, ſupported by reaſon and reflection. The *objects* of courage are the evils of life; and the office of fortitude is to qualify our fears of thoſe evils, that they may never confound and aſtoniſh the

mind; and when any of them arrive, to encounter and ſuſtain them with an equal mind. Fortitude will alſo arm us with reſolution to perform any action which duty demands, however difficult or hazardous; and to perſevere in well-doing, though with the proſpect of various evils; and when any of theſe befal us, courage will ſo ſtrengthen and ſupport us, that we may not ſink under them, or be tempted, through impatience, to forſake our duty. Courage, we may obſerve, does not exclude all fear, and therefore the declaration of Ariſtotle, Ἀφοβος ὁ Ανδρειος, the valiant is fearleſs, muſt be underſtood in a qualified ſenſe. There are ſome things which ought to be feared; for as Ariſtotle obſerves (Ad Nicom. l. iii. c. 6.), "it is for a man's credit to fear infamy, and his diſgrace not to be afraid of it." To which we may add, the diſpleaſure of an almighty God. Not to fear infamy, as the moraliſt now cited obſerves, is a ſign of impudence; and not to fear God is a ſign of impiety. As there are ſome evils which ought to be feared, there are alſo ſome conſtitutions, in which it is impoſſible that fear ſhould be wholly extinguiſhed by fortitude; its office in this caſe is ſo to moderate and rule the paſſion of fear, that it may not deprive him of ſelf-poſſeſſion, and of the full uſe of his reaſon and liberty. In eſtimating the degree of fortitude, and its value in a moral view, allowance ſhould be made for the difference of conſtitutions and of circumſtances. The *rule* or *meaſure* of fortitude is a conſcientious prudence; and conſequently, if we conſider it as a moral virtue, it then does not pertain to the ſoldier, who fights merely for pay or fame; to the man of honour, who gives or accepts the challenge; and much leſs to the ſelf-murtherer. Fortitude, according to the definition given of it by Cicero (De Off. l. ii. c. 13.), is a ſuperiority of mind both to pain and labour; and agreeably to this definition, we may diſtinguiſh fortitude into *active* and *paſſive*: the former denotes a virtuous ardour of mind, which carries a man on towards the glorious end he has in view, notwithſtanding the labours, dangers, and difficulties that lie in the way; and this again may be divided into *civil* and *military*, to the former of which Cicero (De Off. l. i. c. 22.) gives the preference. To this we may apply the fine lines of Horace (l. iii. od. 3.)

"Juſtum, et tenacem propoſiti virum,
Non civium ardor prava jubentium,
Non vultus inſtantis tyranni
Mente quatit ſolida:———"

"The man reſolv'd and ſteady to his truſt,
Inflexible to ill, and obſtinately juſt,
May the rude rabble's inſolence deſpiſe,
Their ſenſeleſs clamours, and tumultuous cries:
The tyrant's fierceneſs he beguiles,
And the ſtern brow, and the harſh voice defies,
And with ſuperior greatneſs ſmiles."—Addiſon.

Paſſive fortitude imports a mind firm and erect under evils.

The extremes of this virtue are, on the one hand, raſhneſs and inſenſibility, and, on the other, timidity and impatience. The virtues reducible to this head of courage, are magnanimity, equanimity, patience, meekneſs, conſtancy, and preſence of mind.

Some writers have diſtinguiſhed between fortitude and courage, repreſenting the former as being always a virtue, and the latter as a virtue or vice, according to circumſtances. Thus, a contempt or neglect of danger, without regard to conſequences, may be called courage, which depends partly on habit, partly on ſtrength of nerves, and partly on want of conſideration; whereas fortitude is the virtue of a rational and reflecting mind, and is founded on a ſenſe of honour and regard to duty. Fortitude, as it reſpects different ſorts of evils, is variouſly denominated; with reſpect to danger in general, it is called intrepidity; in reference to the perils of war, valour; with reſpect to pain of body or diſtreſs of mind, patience; as it reſpects labour, activity; in reference to injury, forbearance; and to the general condition, magnanimity.

FORTORE, in *Geography*, a river of Naples, which runs into the Adriatic, two miles E. of Civita a Mare.

FORTRESS. Although it is common to call every defenſible work a fortreſs, that deſignation cannot in ſtrictneſs apply to any which are not fortified in ſuch manner as may be perfectly independent, and capable of holding out, until, by means of a breach in ſome part of the main defences, an enemy may be authorized to force an entrance. With reſpect to a *coup de main*, every fortreſs is equally ſubject when inſufficiently garriſoned, or deſtitute of proviſions and of ammunition, or if proper precautions are not taken to prevent a ſurprize. According to the rules of defence, every fortreſs ſhould be ſtored for ſix months, or at the leaſt for four; when ſituate near to an enemy's territory, ammunition and proviſion, equal to full eight months conſumption, ought to be laid in; ſo that the garriſon might maintain itſelf until the return of that ſeaſon, when the ſiege muſt, generally ſpeaking, be raiſed. The importance of a poſition, for inſtance, ſuch as Gibraltar, may demand, that ſtores of every deſcription for two years be properly ſecured in bomb-proofs. With reſpect to the general principles of *fortification*, we muſt refer our readers to that head; as alſo to Construction, *Military*, under both which much uſeful information will be found.

FORTROSE, in *Geography*, ſituated on the north-ſide of the Murray frith, is a royal burgh, compriſing two towns, *viz.* Roſemarkie and Chanonry, united under a charter granted by king James II. in the year 1444, and confirmed with greater immunities by James VI. in 1612. Roſemarkie was of high antiquity, having been erected into a royal burgh by Alexander II. Chanonry lies nearly a mile to the weſt, and is ſo denominated from having been at one period the reſidence of the biſhop of Roſs, but is now the ſeat of a preſbytery. By virtue of its charters it was entitled to enjoy the ſame privileges and liberties as the town of Inverneſs; and, conjointly with the latter town, Nairn and Forres, ſends one member to the Britiſh ſenate. It is deſcribed at that time as a place of conſequence, where the arts and ſciences flouriſhed; and the ſeat of law, phyſic, and divinity, for this part of the kingdom. The town, at preſent ſmall, compriſing 278 houſes, and 1289 inhabitants, ſtill owes the little conſequence it poſſeſſes to the recent eſtabliſhment of an academy, under the direction of a rector and two maſters, for the inſtruction of youth in claſſical learning and natural philoſophy. Two parts of the ancient cathedral remain: one uſed as a place of ſepulture for the family of Mackenzie; and the other as a ſeſſions-houſe, the vaults below ſerving for a priſon.

Dr. George Mackenzie, the author of the "Lives of the moſt eminent Writers of the Scots' Nation," was a native of this place.

Eight or nine miles N. W. of Fortroſe, on the road to Dingwall, lies the barony of Ferrintoſh, in the pariſh of Urquhart, which poſſeſſed, from 1690 to 1786, an exemption from the duties of exciſe on ſpirits diſtilled from grain of the growth of that diſtrict. N. lat. 57° 34′. W. long. 4° 5′.

FORTUNA Equestris. See Equestris.

Fortuna, in our ancient *Law-Books*, is the ſame with what we call *treaſure trove*.

"Theſaurum

"Theſaurum ducente fortuna invenire inquirendum eſt per 12 juratores pro rege, &c. quod fideliter preſentabunt, &c. omnes fortunas, abjurationes, appella, &c."

Some pretend it alſo ſignifies *fortuito occiſos*; but this ſeems to be very fanciful.

FORTUNATE ISLANDS, in *Ancient Geography*, an appellation which has given the critics and antiquaries great perplexity; being the name of a place famous for golden apples which grew there; or, as Varro ſays, for ſheep with golden fleeces.

The ancients deſcribe them as ſituate without the ſtraits of Gibraltar, in the Atlantic ocean. The common opinion of the moderns takes them for the Canary iſlands; this is grounded principally on the ſituation and temperature of thoſe iſlands, which render the uſe of cloaths there unneceſſary; and from the abundance of oranges, lemons, grapes, and other delicious fruits growing there.

Ol. Rudbecks has found a very different place for them. That learned author, who makes his native country, Sweden, the ſcene of all that is great and extraordinary in ancient tradition and fable, will have the Fortunate iſlands to be Sweden, and the delicious fruits, talked of by the ancients, his imagination ſuggeſts were nothing but the virtue and good manners which anciently flouriſhed in that cold hyperborean nation.

FORTUNE, Τυχη, is a name unknown in the earlier ages; and does not occur, as a divinity, either in Homer or Heſiod; as not being invented in their time.

In after-days it was introduced as a machine; and made to ſerve diverſe purpoſes in natural philoſophy and theology.

The moſt ancient circumſtance we know concerning this goddeſs is, that Bupalus, a great ſtatuary and architect, was the firſt who made a ſtatue for her in the city of Smyrna; and that this ingenious artiſt thought fit to repreſent her with the polar ſtar upon her head, holding in her left hand the horn of Amalthea, commonly called the Cornucopia. By the firſt of theſe ſymbols he is thought to have deſigned to expreſs the power of this goddeſs over the world, and by the ſecond that ſhe was the diſpenſer of all goods. After him came Pindar, continues Pauſanias, who celebrated this divinity in his verſes, and gave her the name of Pharopolis, or the protectreſs of cities; ſuch is nearly the origin of the worſhip of Fortune in Greece, a modern divinity not known before Pindar. In after-times the Greeks erected to her ſeveral temples. The inhabitants of Antioch, as well as thoſe of Smyrna, held her in high veneration; and it is not improbable that ſeveral other people imitated their example. Among the encomiums given to this goddeſs by Pindar, he made her one of the Parcæ, and to have the greateſt power of them all, whence we may conclude, that ſhe was confounded with thoſe inexorable goddeſſes, or, ſpeaking more accurately, with Deſtiny itſelf, that blind divinity, who diſtributed good and evil at random: and ſuch was the idea which the Greeks entertained concerning her.

The Romans conceived of her in a ſimilar manner; ſince their moſt ancient Fortune being that which was worſhipped at Antium, and which was confounded with the Lots, the uſe of which was ſo famous in that city, it is evident they did not diſtinguiſh her from Deſtiny, or that fate which the Geeks called *Eimarmene*. The Romans, content at firſt with conſulting the Lots and Fortune at Antium, adopted at laſt this divinity, and eſtabliſhed her worſhip in their city, where ſhe had afterwards a great number of temples. The firſt was erected to her by Servius Tullius, and hence we deduce the date of the introduction of her worſhip into Rome. This edifice was conſecrated to her under different names, under which various appellations ſhe had appropriate temples, as we learn from Livy and Plutarch. A ſecond temple was built by Ancus Martius to Fortune, under the title of *Fortuna virilis*; and ſhe had likewiſe another under the name of *Female fortune*; and none but newly married perſons were permitted to worſhip her. It is probable, that the Roman ladies were at the charge of building that edifice; accordingly it was reported, that at the finiſhing of it, the goddeſs had uttered theſe words, "Recté me matronæ vidiſtis, ritéque dedicaſtis." Fulvius Flaccus raiſed the moſt magnificent temple of all to this goddeſs, under the appellation of the "Equeſtrian fortune." That which was erected to her by Q. Catulus was dedicated to the "Fortune of the day," *Fortunæ hujuſce diei*. If that which Nero conſecrated to her was not the moſt magnificent, it was the moſt ſingular and ſplendid, in regard to the materials of which it was formed. It was entirely of one ſort of ſtone found in Cappadocia, called by Pliny *Phingias*, the marble of which, beſides its remarkable hardneſs, was ſo white and glaring, that it is ſaid, when the gates were ſhut one ſaw in it clearly. This temple was afterwards incloſed within that emperor's golden houſe. The ſame goddeſs had another in the new ſtreet under the title of "Fortune with breaſts," who was repreſented much like Diana of Epheſus, and Iſis, whoſe head-dreſs ſhe wears upon ſome figures which are ſtill preſerved. Domitian built another temple to "Fortune of happy arrival," *Fortunæ reduci*, an expreſſion which often occurs on medals, as well as that of *Fortuna redux*.

Plutarch, in an expreſs treatiſe of the Fortune of the Romans, accounts for the practice of the ancient poets, who ſeem to make Jupiter the author of all the evils of life. Mankind, he obſerves, before the name of Fortune had got into the world, perceiving a certain arbitrary cauſe, diſpoſing of things in an irreſiſtible manner, called it *God*: but the ſame cauſe being often obſerved to act at random, and without any rule or order at all, the ſupreme being came to be diveſted of the attribute; and Fortune, or Deſtiny, acknowledged in his ſtead.

It is not eaſy to unravel what the ancients meant by the name Fortune. The Romans underſtood by it a principle of fortuity, whereby things came to paſs, without being neceſſitated thereto; but what and whence that principle is, they do not ſeem to have ever preciſely thought; whence their philoſophers are often intimating, that men only framed the phantom Fortune, to hide their ignorance; and that they call Fortune whatever befals a man without his knowing for what purpoſe. Hence Juvenal, ſat. x. ver. 366, affirms, they were men who made a deity of Fortune:

"Nullum numen abeſt, ſi ſit prudentia; ſed te
Nos facimus, Fortuna, deam cœloque locamus."

The ingenious Mr. Spence gives another reading of this paſſage:

"Nullum numen habes, ſi ſit prudentia; ſed te
Nos facimus, Fortuna, deam cœloque locamus."

This reading, he thinks, agrees beſt with the context: Juvenal ſays, ver. 356, that the two things we ſhould pray for are good health and good ſenſe; that we might be the authors of our own happineſs if we pleaſed, ver. 363. that virtue is the only way to true happineſs, ver. 364. that if we ourſelves are prudent, Fortune has no power over us; and that in truth ſhe is no goddeſs at all, and has only uſurped a ſeat in heaven from the folly of mankind, ver. 366. Fortune was not conſidered as a deity by the old Romans, but was made ſo by the devotion and folly of the vulgar; and Mr.

Mr. Spence ſays, that he has ſeen an ancient gem, in which Cybele, the mother of the gods, is repreſented as turning away her head from Fortune, in an attitude of diſowning and rejecting her. Polymetis, p. 150, 154, &c.

According to the opinion of the heathens, therefore, fortune, in reality, was only the arrival of things in a ſudden and unexpected manner, without any apparent cauſe or reaſon; ſo that the philoſophical ſenſe of the word coincides with what is vulgarly called *chance*.

But in religion it had a farther force; altars and temples in great numbers were conſecrated to this fortune, as a deity. This intimates that the heathens had perſonified, and even deified, their chance; and conceived her as a ſort of goddeſs, who diſpoſed of the fate of men at her pleaſure. Hence that invocation of Horace, "O diva, gratum quæ regis Antium," in the thirty-fifth ode of the firſt book, where he recommends Auguſtus, then preparing for a viſit to Britain, to her protection. From theſe different ſentiments it may be inferred, that the ancients at one time took Fortune for a peremptory cauſe, bent upon doing good to ſome, and perſecuting others; and ſometimes for a blind inconſtant cauſe, without any view or determination at all.

If then the word Fortune has no certain idea in the mouth of thoſe who erected altars to her; much leſs can it be aſcertained what it denotes in the minds of thoſe who now uſe the word in their writings.

They who would ſubſtitute the name Providence in lieu of that of Fortune, cannot give any tolerable ſenſe to half the phraſes wherein the word occurs.

Horace paints the goddeſs, preceded by neceſſity, holding nails and wedges in her hands, with a cramp-iron, and melted lead to faſten it; rarely accompanied with Fidelity, unleſs when ſhe abandons a family; for in that caſe Fidelity never fails to depart with her, as well as friends.

She is diſreſpectfully ſpoken of by moſt of the Roman writers, and repreſented as blind, inconſtant, unjuſt, and delighting in miſchief. Ovid. ad Liv. ver. 52. ver. 374. Hor. lib. i. od. 34. ver. 26. lib. iii. od. 29. ver. 51. Statius, Theb. xii. ver. 505. However, they had a good as well as a bad Fortune, a conſtant and inconſtant Fortune, the latter of which was repreſented with wings, and a wheel by her. Hor. lib. iii. od. 29. ver. 56. We are wholly ignorant of the nature of that worſhip which the Romans paid to bad Fortune; but that they did pay homage to her is certain, ſince, according to Cicero (De Nat. Deor. l. iii.), ſhe had an altar on the Eſquiline mount. As the inhabitants of Antium adored at the ſame time two fortunes, called *Fortunæ geminæ*, the twin fortune, it is probable that theſe were good and bad fortune. Martial, who alſo ſays they were ſiſters, adds, that they iſſued forth oracles upon the ſea ſhore. Suetonius calls the two fortunes "the Lots of Antium," becauſe it was by the Lots they were conſulted.

Juvenal alludes to a ſtatue of Fortune, which exhibited her under a very good character, as the patroneſs of the poor infants that were expoſed by their parents in the ſtreets. Sat. vi. ver. 605.

The painters repreſent her in a woman's habit, with a bandage before her eyes, to ſhew that ſhe acts without diſcernment; and ſtanding on a wheel, to expreſs her inſtability. The Romans, ſays Lactantius, repreſented her with a cornucopia, and the helm of a ſhip, to ſhew that ſhe diſtributes riches, and directs the affairs of the world. In effect, it is with ſuch characters, that we ſee her repreſented on ſo many medals, with the inſcriptions, FORTVNA AVG. FORTVNA REDVX. FORTVNAE AVG. or REDVCIS, &c. Sometimes ſhe is ſeen pointing at a globe before her feet, with a ſceptre in one hand, and holding the cornucopia in the other.

The Romans, as he have already obſerved, had a virile as well as a muliebrian Fortune for the objects of their adoration: the *Fortuna virilis* was honoured by the men, and the *Fortuna muliebris* by the women.

They honoured Fortune alſo under a variety of other appellations. The Fortune worſhipped at Antium was probably of the moſt exalted character of any among the Romans, if we may judge by the account which Horace gives us of the great ſolemn proceſſions that were made to her. Hor. lib. i. od. xxxv. ver. 22. But the moſt celebrated temple of Fortune was at Prænefte. Statius ſpeaks of ſeveral Fortunes there, and calls them the *Prænefſinæ ſorores*. Lib. i. Sylv. iii. ver. 80.

On the reverſe of a medal of Commodus, we have a repreſentation of Fortune, under the quality, or ſurname of *Manens, i. e. ſtable, permanent;* holding a horſe by the reins. On the Greek medals we meet with ΑΓΑΘΗ or ΚΑΛΗ ΤΥΧΗ, *Good Fortune.* Conſtantine gave the epithet *anthouſia, i. e. flouriſhing*, to the Fortune of his new city Conſtantinople.

FORTUNE, *Part of.* See PART.

FORTUNE *Bay*, in *Geography*, a bay on the S. coaſt of Newfoundland; 20 miles N. W. of Placentia bay. This extenſive bay is interſperſed with ſmall iſles, and within it are many bays, with great depth of water.

FORTUNE *Iſland*, or *Good Fortune Iſland*, a ſmall iſland in the Indian ſea, near the S. W. coaſt of the iſland of Sumatra. S. lat. 1° 35′. E. long. 90° 25′.—Alſo, a ſmall iſland in the Eaſt-Indian ſea, near the N. coaſt of the iſland of Celebes. N. lat. 0° 50′. E. long. 123° 48′.

FORTUNE, *Iſlands of*, two ſmall iſlands and rocks, near the W. coaſt of Kerguelen's land. S. lat. 49° 21′. E. long. 68° 15′.

FORTUNE-*tellers*. Pretenders to tell fortunes, and to any crafty ſcience for the diſcovery of ſtolen goods, are puniſhable by impriſonment, pillory, and binding to their good behaviour, and ſhall be deemed vagabonds. Stat. 9 Geo. II. cap. 5. ſect. 4. Stat. 17 Geo. II. cap. 5. ſect. 2. See CONJURATION.

FORTY DAYS. See QUADRAGESIMA, and LENT.

FORTY *days court*. See ATTACHMENT *of the foreſt*.

FORTY *hours, prayers of*. See HOURS.

FORTY-*ſhilling Land*, in *Agriculture*, is a term applied in Scotland to a certain portion of arable land. But the forty-ſhilling land of old extent conſiſted of eight *oxgangs*, or one hundred and four acres.

FORULI, in *Ancient Geography*, a town of the Sabines, mentioned by Virgil. According to Strabo, it was ſeated on a rock, and very favourable in this reſpect for the accommodation of thoſe who might at any time engage in a revolt. Its preciſe ſituation is not aſcertained.

FORUM, in *Antiquity*, is uſed in divers acceptations; ſometimes for a place of traffic, anſwering to our market-place; in which ſenſe it has uſually ſome adjective added to it, as *forum boarium*, market for oxen and beef; *forum ſuarium*, for ſwine; *forum piſcarium*, for fiſh; *forum piſtorum*, for bread; *forum cupedinarum*, for dainties; and *olitorium forum*, the herb-market.

FORUM, again, is uſed for any place where the governor of a province convenes his people to give judgment, according to courſe of law.

Whence a man is ſaid *forum agere*, when he keeps the aſſizes; *forum indicere*, when he appoints the place where they are to be kept, &c.

FORUM was alſo a public ſtanding place in the city of

Rome, where cauſes were judicially tried, and orations delivered to the people.

Of theſe *fora*, called *civilia*, in contradiſtinction to thoſe of the firſt kind above-mentioned, which were denominated *venalia*, there were ſeveral; at firſt only three, *viz.* Romanum, Julianum, and Auguſtum; but that number was afterwards increaſed to ſix, by the addition of the Tranſitorium, called alſo Palladium; the Trojanum, and Saluſtii forum.

The firſt, and moſt eminent of theſe, was the forum Romanum, called alſo *forum vetus*; and abſolutely, *forum*, or *the forum*. In the time of Romulus this was only a large open ſpace without buildings or any other ornament. Tullus Hoſtilius firſt incloſed it; the elder Tarquin adorned it with porticos; and ſucceeding kings, conſuls, and magiſtrates, rendered it at length one of the nobleſt places in the world. It was called "Forum Romanum," or ſimply "Forum," by way of eminence, on account of its antiquity in compariſon of the other *fora*, and of its moſt general uſe in public affairs. Martial and Statius, for the ſame reaſon, give it the name of "Forum Latium;" Ovid the ſame, and of "Forum Magnum;" and Herodian calls it τὴν ἀρχαίαν ἀγορὰν, the old forum. The Comitium, uſed ſometimes for holding the *comitia* (which ſee), was a part of this forum, in which ſtood the *roſtra* (which ſee), a ſort of pulpit, adorned with the beaks of ſhips taken in a ſea-fight from the inhabitants of Antium. In this the cauſes were pleaded, the orations made, and the panegyrics ſpoken by perſons at the death of their friends or relations. Near this was the "Puteal." Of this place critics have given different accounts; but the opinion of M. Dacier ſeems to be the moſt probable; who ſays, that the Romans, whenever the thunder fell upon a place without a roof, took care, from ſuperſtitious motives, to have a ſort of cover built over it, which they called "Puteal." This had the name of "Puteal Libonus," and "Scribonium Puteal," becauſe Scribonius Libo erected it by order of the ſenate. The prætor's tribunal, which ſtood very near it, is often denoted by the ſame expreſſion.

The "Julian forum," called alſo "Cæſar's," was built by Julius Cæſar with the ſpoils taken in the Gallic war. Its area alone, as Suetonius informs us, coſt one hundred thouſand ſeſterces; and Dio affirms, that it much exceeded the Roman forum.

"Auguſtus's forum" was built by Auguſtus Cæſar, and was reckoned by Pliny among the wonders of the city. The moſt remarkable curioſity it preſented was the ſtatues in the two porticos on each ſide of the main building. In one were all the Latin kings, beginning with Æneas; in the other, all the kings of Rome, beginning with Romulus; moſt of the eminent perſons in the commonwealth, and Auguſtus himſelf among the reſt; with an inſcription upon the pedeſtal of every ſtatue, expreſſing the chief actions and exploits of the perſon it repreſented. This forum was reſtored by the emperor Adrian.

"Nerva's forum" was begun by Domitian, but finiſhed and named by the emperor Nerva. In this forum Alexander Severus ſet up the ſtatues of all the emperors that had been deified, in imitation of what Auguſtus had done in his forum. This forum was called "Tranſitorium," becauſe it lay very convenient for a paſſage to the others; and "Palladium," from a ſtatue of Minerva which was ſet up in it. Scarcely any thing remains of this forum, except an old decayed arch, which the people, by a ſtrange corruption, inſtead of Nerva's arch, call Noah's ark.

"Trajan's forum" was built by the emperor Trajan with the produce of the ſpoils which he had taken in his wars. The porticos round this forum were exceedingly beautiful and magnificent, covered with braſs, and ſupported by pillars of more than ordinary ſize, and exquiſite workmanſhip.

The forum of Conſtantinople was erected by Conſtantine, when he eſtabliſhed this city on the commanding eminence of the ſecond hill, where he had pitched his tent, during the ſiege and conqueſt of Byzantium. This edifice was of a circular, or rather elliptical form: the two oppoſite entrances formed triumphal arches; the porticos, which incloſed it on every ſide, were filled with ſtatues; and the centre of the forum was occupied by a lofty column, of which a mutilated fragment is now degraded by the appellation of the "burnt pillar." This column was erected on a pedeſtal of white marble, twenty feet high; and was compoſed of ten pieces of porphyry, each of which meaſured about 10 feet in height, and about 33 in circumference. On the ſummit of the pillar, above 120 feet from the ground, ſtood the coloſſal ſtatue of Apollo, which was of bronze, and had been tranſported hither from Athens or from a town of Phrygia; and was ſuppoſed to be the work of Phidias. The artiſt had repreſented the god of day, or, as it was afterwards interpreted, the emperor Conſtantine himſelf, with a ſceptre in his right hand, the globe of the world in his left, and a crown of rays glittering on his head. This ſtatue was thrown down under the reign of Alexis Comnenus.

FORUM is alſo uſed among Caſuiſts, &c. for juriſdiction. Thus they ſay *in foro legis*, or the outer forum, *i. e.* in the eye of the laws, or the common courſe of juſtice: *in foro conſcientiæ*, or the inner forum, *i. e.* in the eye of God, or man's own conſcience.

There are a great many things not condemned *in foro legis*, which yet are criminal *in foro conſcientiæ*.

FORUM *Adriani*, in *Ancient Geography*, *Voorbourg*, a place in Inſula Batavorum, S.E. of Lugdunum Batavorum; where Adrian eſtabliſhed a kind of mart for the purpoſe of carrying on his negociations with Great Britain.——*Alieni*, a town of Gallia Ciſpadana, inhabited by the Lingones; now *Ferrara*.——*Appii*, a town of Italy, in Latium, on the Appian way, at the 43d mile-ſtone from Rome; built by Appius, who formed the way denominated from him. See FOSSA *Nuova*.——*Aurelii*, a town of Italy, in Etruria, between Centumcellæ and Coſa; long ſince utterly deſtroyed.——*Ceramorum*, a conſiderable town of Aſia, and the laſt of Myſia, 12 paraſangs from Peltæ.——*Calviſii*, *Calviſano*, a town of Italy, in Gallia Ciſalpina, in the canton of the Cenomanes.——*Caſſii*, *S. Maria Forcaſſi*, a town of Italy, in Etruria, between Tarquinii to the weſt, and Falarii to the eaſt.——*Claudii*, *Oriolo*, a maritime town of Italy, in Etruria, to the ſouth-eaſt of Carara.—Alſo, a town of Gaul, in the province of the Alps, the capital of the Centrones.——*Cornelii*, *Imola*, a town of Gallia Ciſpadana, W. of Ravenna, and S.E. of Bologna.——*Decii*, a town of Italy, in the country of the Sabines; ſuppoſed to be at or near *Furano*.——*Diuguntorum*, or *Jutuntorum*, *Crema*, a town of Inſubria (Ptol.), in Gallia Tranſpadana, S. of Bergomum.——*Egurrorum*, a town of Spain, in the Tarragonnenſis, ſeated on the Silus, in the country of the Aſturi, W. of Aſturica; ſuppoſed to be the preſent *Medina de Rio Seco*.——*Flaminii*, a town of Italy, S.W. of Nuceria.——*Fulvii*, a town of Italy, in Liguria, ſeated on the Padus, N.W. of Dertona; ſuppoſed to be Valence, in the duchy of Milan.——*Gallorum*, *Caſtel-Franco*, a ſmall town of Gallia Ciſalpina, S.E. of Mutina.—Alſo, a town of Spain, in the Tarragonnenſis, and country of the Vaſcones, N.W. of Oſca.——*Julii*, *Frejus*, a town ſituated on the coaſt of Gallia Narbonnenſis, W. of the iſland of Lero. See FREJUS.——*Lebuorum*, or *Libicorum*, a town of Italy,

in

in Gallia Cifalpina; fuppofed to be *Borgo Lavizaro*, in the duchy of Milan.——*Lepidi, Regio*, a town of Italy, in Gallia Cifalpina.——*Licinii, Pieve d' Incino*, a town of Italy, in Gallia Tranfpadana, in the canton of the Orobii.——*Limicorum, Ponte de Lima*, a town of Spain, in the country of the Callaici Braccarii, fituated on the Limia——*Livii, Forli*, a town in the S.E. part of Gallia Cifpadana.——*Narbafarum*, a town of Spain, in the territory of the Callaici, towards the confines of Lufitania, S.E. of Aquæ Flaviæ.——*Neronis, Forcalquier*, a town of Gallia Narbonnenfis, N.E. of Catuiaca.——*Novum, Fornove*, a town of Gallia Cifpadana, towards the fouth, near the Tarus. —Alfo, a town of Italy, in the Samnium, N.E. of Beneventum, and at a fmall diftance from it. Its ruins appear near Paduli. —Alfo, a town of Italy, in the country of the Sabines; the fame, according to the abbé Chauppy, with *Forum Decii*.——*Popilii*, a town of Gallia Cifalpina, S.E. of *Forum Livii*.—Alfo, a town of Italy, in Lucania, S.E. of Vulci.——*Segufianorum*, a town of Gallia Celtica; now *Feuris en Forez*.——*Sempronii, Foffombrone*, (which fee,) a town of Italy, in Ombria, upon the Metaurus, S.E. of Urbinum Metuarenfe.——*Statielliorum, Villa de Fo*, a town of Italy, in Liguria.——*Tiberii, Keyferftulh*, Germ. denoting the throne of Cæfar, a town of Gallia Celtica, belonging to the Helvetians, fituated on the Rhine, not far from the frontier of the Rhætii and Vindelicii.——*Truentinorum*, a town of Gallia Cifalpina, in Emilia.——*Vibii*, a town of Gallia Cifalpina, in the country of the Taurini.——*Voconii, le Canet*, a town of Gallia Narbonnenfis, 22 miles W. of Forum Julii. When the fenate of Rome was delivered from the horror of profcriptions, it caufed to be erected in this place a temple to Clemency, in which they fet up the ftatue of this virtue, together with that of Cæfar, to whom fhe prefented her hand.——*Vulcani, Solfatara*, a place of Italy, in Campania, near Puzzuoli. Pliny calls it the the Campi Phlegræi.

FORWARD, a word of command, ufed in our *Military Tactics*, when it is intended that fections, platoons, or battalions, &c. fhould advance in that direction to which they are at the time fronted. Forward-wheeling is likewife ufed in contradiftinction to backward-wheeling, as explained under the heads of Evolution and Tactics. The former caufes the wheeling body to be thrown in advance of its former pofition; the latter places it behind the line it had occupied. The many inconveniences attendant on wheeling forward have occafioned that mode to be lefs ufed than formerly; wheeling backwards being found to anfwer far better in all cafes where there may be fufficient fpace towards the rear to admit of the feveral fections, platoons, &c. being thrown back. No larger body than a grand divifion, which we fuppofe to contain nearly 200 men, ought ever to wheel forward; nor more than a fingle company, rated at 100 men, to wheel backward.

FORZA de Agro, in *Geography*, a town of Sicily, in the valley of Demona; 20 miles S. of Meffina.

Forza, *St. Leonardo*, a town of Naples, in the Abruzzo Citra; 6 miles E.S.E. of Valva.

FOS di Novo, a town of Etruria, and capital of a marquifate, to which it gives name; 4 miles E. of Sarzana.

FOSCAGNO, a town of Italy, in the county of Bormio; 8 miles N.N.W. of Bormio.

FOSCARINI, Michael, in *Biography*, a noble Venetian, born in 1728, was employed by his government to continue the hiftory of Venice by Nani. His part of the work forms the tenth volume of the "Collection of Hiftorians of Venice." It is in 4to., and was publifhed in the year 1718. He died in 1692, leaving likewife behind him two novels, which are printed among thofe of the Academy of Incogniti.

FOSENO, in *Geography*, a fmall ifland in the North fea, near the coaft of Norway. N. lat. 60° 45'.

FOSEY, a town of Bengal; 20 miles S.S.E. of Mahmudpour.

FO-SHAN, or Fo-chan, a village of China, fo called becaufe it is not inclofed by walls, and has not a particular governor, although it carries on a great trade, and contains more houfes and inhabitants than even Canton itfelf. This village, which is diftant four leagues from Canton, is reckoned to be three leagues in circumference, and to contain a million of inhabitants, who are occupied in various manufactories.

FOSS, or Fosse, a river of England, which runs into the Oufe, near York.

Foss *Navigation*, is the parliamentary name of an inland navigation, purfuing the courfe of the Fofs river in the North Riding of Yorfhire, from the Ouſe river at York city, to a place called Stillington Mile. See Canal.

Foss, or *Foffe*, in *Fortification*, a French word, literally meaning a ditch, adopted in our language, and efpecially applied to the ditch or moat furrounding fortified places, or made in the front of entrenchments, &c. for the purpofe of preventing furprize, and of protracting the defence made by the garrifon. Under the head of Construction, *Military*, the proper dimenfions and form of that excavation which furnifhes foil for the formation of the ramparts, and which becomes the foffe, will be found exemplified according to the fyftems adopted by the moft eminent engineers; it would therefore be fuperfluous to repeat in this place all that intereſting detail which under that ticle referred to may be feen, not only abftractedly, but according to the feveral relations the foffe bears to the feveral members of the fortification. Here we fhall confine ourfelves to a few remarks relating to the advantages attendant upon dry and upon wet ditches.

Wherever the opportunity may offer, it fhould be made a rule to conftruct the ditch fo that it could be filled with water at pleafure. For this purpofe, ample fluices ought to be laid, fhutting with gates in the ordinary manner, but effectually fecured from the enemy; who might otherwife choak the channels, and prevent the gates from opening; or, if it fhould better fuit their purpofe, might open the gates, fo as to allow the water to retire with an ebbing tide, &c. Much will depend on the manner in which that part of the ditch lying between the curtain and the raveline in its front, may be occupied. If there be a tenaille, and that it be intended to keep that fpace dry, fo as to allow of large bodies of troops proceeding from the principal, or body of the place, to the tenaille, and from that to the raveline, or *vice verfâ*, it will be neceffary to throw up embankments in the form of *demi-caponnieres*, from that part of the revetement under the orillon, to the interior line of the rampart; thus cutting off the flow of water, and confining it to thofe parts of the ditch in front of the feveral baftions, and under the ravelines, &c. into all which it fhould flow through proper arched channels.

The embankment above-mentioned is called a *batardeau*, and is ufually furnifhed with a row of very ftout paliſades, which being below the ordinary level of thofe fhots directed at the flanks of the baftions, commonly efcape injury until the enemy may be able to make a lodgment on the creft of the glacis. Of courfe, under proper precautions, the batardeau proves an efficient means of preventing any *coup de main* in that quarter from fucceeding.

In order to ftrengthen the defences ſtill more, it is common to fink channels called *cunettes*, or *cuvettes*, in the centres of the ditches, parallel with the faces of the baſtions.

These ſhould be from 14 to 16 feet wide, and about nine or 10 feet deep; the ſides being lined with maſonry: the cunette is ordinarily kept full of water, and proves an admirable preſerve for large quantities of fiſhes; which being under the notice of various centinels, are not ſubject to be poached. The cunette is likewiſe a great check upon thoſe who may be diſpoſed to deſert, and ſerves as a formidable impediment to the ſmuggling of ſpirits, &c. into the body of the fortreſs.

It muſt be obvious that a wet ditch muſt preſent numerous obſtacles in the way of the beſiegers, who cannot always command the means of paſſing a foſſé from 30 to 50 yards broad, perhaps from 12 to 24 feet deep, and having a cunette ſunk along its centre; even though they ſhould have breached the flanked angles of a baſtion, and made a lodgment in the covert-way. But, on the other hand, the difficulty of maintaining the communication between the body of the place and the outworks during a ſiege, when the bridges are ordinarily much damaged, and perhaps rendered unſerviceable, is a great drawback on this kind of defence. The embarraſſments to which ſuch a circumſtance as the want of a competent bridge may give birth, muſt be too obvious to require any detail. A dry ditch affords conſiderable convenience to the garriſon, not only in the ordinary way of communication, but it enables large bodies of men to paſs freely, and with far leſs expoſure than on a bridge, to and fro; ſo that a ſally may uſually be made with promptneſs and ſecrecy. Should the enemy poſſeſs themſelves of a raveline, the defenders may eſcape into the ditch by means of ſmall eſcaliers of maſonry, commonly called *pas de ſourés*, and take ſhelter in the tenaille, if there be one; otherwiſe they may retire into the flanks of the baſtions by means of eſcaliers concealed behind the orillons. In a wet ditch no additional works can be conſtructed; whereas, in a dry one, ſuch retrenchments, or even redoubts, may be raiſed, as may not only give the enemy conſiderable trouble, but eventually ſerve to diſlodge him, or to render what would otherwiſe have proved important acquiſitions, perfectly uſeleſs and unavailing.

But in ſome ſituations it is impoſſible to keep a foſſé of proper depth free from water; while in others, whether owing to the looſeneſs of ſoil, or to the elevation of the works above the ordinary level of the country, it is equally ſo to obtain any adequate depth of water. Beſides, in ſuch elevated ſituations, it may often be in the power of the enemy to drain off the water. Where a very ample body of water can be retained above the ordinary level of the country, and the ſurrounding plain contiguous to the defences may lie very low, it may be ſometimes practicable to let off the water ſuddenly, thereby to form a moraſs, ſuch as muſt give the beſiegers infinite trouble.

Foss, *Advance*. See Advance.

Foss, *Van*. See Van.

Foss-*way*, is one of thoſe celebrated great roads, that traverſed this iſland at a very early period of its hiſtory, veſtiges of which are traceable in various diſtricts; while, in others, they have been obliterated by the progreſs of cultivation, or the direction of the lines coaleſcing with the preſent turnpike roads. It has been generally admitted by antiquarian topographers, that four principal ways, or ſtreets, as they have been uſually termed, extended from ſeveral points of the compaſs, and, paſſing through the interior, formed lines of communication with the oppoſite coaſts. But the accounts given of them are ſo obſcure and contradictory, as to form a very inadequate clue for purſuing their courſe with deſired exactneſs; while the deſtructive hand of time, and the labours of huſbandry, by daily diminiſhing their remains, render the taſk of aſcertaining the bearing progreſſively more difficult. The four great roads were the Hermine or Ermine ſtreet, the Icknild or Ricknild ſtreet, the Watling ſtreet, and the Foſs-way. Beſides theſe, there were two other great roads, but of leſs extent, *viz.* the Via Devana and the Julia Strata; with numerous croſs and connective communications, denominated vicinal ways, which were the means of intercourſe between the ſeveral ſtations; the names and diſtances between which formed the ſubject of the curious topographical work, the Itinerary of Antoninus.

As to whom theſe early great national improvements are attributable, no doubt can be fairly entertained: for, though Ranulphus Higden, in his Polychronicon, aſcribes them to Molmutius, a Britiſh king; and a manuſcript, entitled Eulogium, preſerved in the Cotton collection, adduces them as the work of Belinus, the ſon of Molmutius; and theſe opinions have been adopted, without examination; yet from the accounts given of the labours and improvements of the Romans, while in poſſeſſion of Britain, and the internal evidence ariſing from the conſtruction of the roads, they are decidedly referable to that ingenious people. It is well aſcertained, that the Roman method of forming roads was to lay the foundations deep, and to uſe ſuch durable materials that they became perfectly ſolid buildings, and ſo compact that they could not have been more firm if vaulted and arched. A ſection made of a portion of the Foſs-way, for the purpoſe of diſcovering the mode of conſtruction, and the kind of materials uſed in theſe roads, afforded the following reſult: Stones, clunch, hard gravel, indurated clay, and various other kinds of earth, in layers, like the ſtrata obſervable in mines; a layer of clay was ſucceeded by a ſubſtance of a binding quality, then a layer of flat ſtones, next chalk, over which was laid rough gravel, till the road was raiſed from ſix to eight feet in height, and the top crowned or coped with a ridge, gently riſing from the ſides to the centre, that the rains falling upon it might run off, leſt by ſoaking in they might ſoften the cementing bodies, and injure the work. Similar ſubſtances and plans of conſtruction have been apparent in the other great roads, in places where they have been broken up, to take the materials for repairing adjacent highways.

Theſe muſt have been arduous and expenſive undertakings, at a time when the country was in ſuch an unimproved ſtate, that the very attempt to remove the difficulties of communication was a ſtriking proof of their exiſtence and inconvenience. But the Romans, as lords of the countries they conquered, poſſeſſed the wealth of labour to a vaſt extent: they had the command of the natives, their carriages and cattle; while the ſoldiers alſo, when unoccupied in military expeditions, were conſtantly employed in works of public utility. If, therefore, the requiſite materials lay at a conſiderable diſtance, they had the means of procuring and tranſporting them to the deſired places: and ſuch was the enterpriſing and decided character of that people, they would have whatever conſtructive materials they might chooſe, that their works, as bridges, roads, aqueducts, fortifications, &c. ſhould be grand and magnificent like themſelves.

Reſpecting the bearing of theſe roads, much has been advanced by hiſtorical and topographical writers; and it ſtill forms an intereſting ſubject of antiquarian reſearch. A manuſcript, marked Nero D 1, among other additamenta at the end of Matthew Paris's works, in the Britiſh Muſeum, contains a rude draught and deſcription of theſe roads, which, from recent diſcoveries, and attempts to aſcertain their reſpective lines and bearings, appears tolerably correct.

correct. In this plan, the Hermine or Ermine ſtreet is repreſented as proceeding from the ſouthernmoſt part of the iſland, directly north; the Icknild or Ricknild ſtreet, in a line from eaſt to weſt; the Watling ſtreet, from Dover to Cheſter; and the Foſs-way, from Totneſs in Devonſhire to Caithneſs in the north-eaſt of Scotland. But as it does not appear that the Romans ever penetrated further north than the ſouthern bank of the river Tay, it is more probable that this, like the Hermine ſtreet, terminated at the Linea valli, or Roman wall. The ſouthern end perhaps might have been at the city of Exeter, the Iſca Danmoniorum of the Itinerary, and the ſtation where the legio ſecunda of the Roman army was quartered, while their operations were confined to Britannia Prima. Of the track the Foſs-way made through the counties of Devon and Somerſet few veſtiges have been diſcovered. It has been traced in the vicinity of Bath, the Aquæ Solis of Antoninus, where it was met by another road, which, coming weſtward from the Severn, formed a continuation of the Julia Strata. Entering Wiltſhire, the Foſs paſſes North Wraxal to Shire-ſtone, and leaving Tetbury about a mile and a half to the eaſt, enters Glouceſterſhire, near the village of Kemble, proceeding to the ſtation of Durocornovio, the preſent town of Cirenceſter; where it is traverſed by another Roman road coming from the ſouth-eaſt, on which are the ſtations deſcribed in the fourth Iter; and which is ſtill recorded by the names of ſeveral places on the line retaining the Britiſh name of *Sarn*, equivalent to the Latin *ſtratum*, *viz.* North and South Sharncote, Sharnton, Sarney, &c. The progreſs of the Foſs from Cirenceſter is through Northleach, Slaughter, Stow-on-the-Wold, Moreton-in-Marſh, and Lemington, where it receives a vicinal, or croſs road, leading, according to Dr. Plot, from Woodſtock in Oxfordſhire. Leaving Lemington, and paſſing Stratton-in-the-Foſs to Whitchurch, it enters Warwickſhire at Stretton-ſuper-Foſs. Along this part of the line it is very conſpicuous, running through an iſolated part of Worceſterſhire, croſſing the river Stour at Hawford; and a little to the weſt of Compton, Combrook, and Lighthorn, it leads to a large Roman encampment at Cheſterton, near which it takes a direction over the river Leam, on the eaſt of Honingham, to Upper Stretton; whence it is very viſible over Dunſmore heath, in its courſe to Britford-upon-the-Avon; and going by the village of Brinklow, through Stretton-under-Foſs, where it appears like an open ditch, the materials having been taken away for repairing ſome adjacent road; and leaving Monk's Kirby on the eaſt, it bids adieu to this county at Highcroſs, interſecting the Watling ſtreet at nearly right angles, at which junction was the ſtation Bennonæ. Through Leiceſterſhire it ſhapes its courſe almoſt parallel with the river Soar near Sharnford, which derives its name from the road, as did the places previouſly mentioned in Glouceſterſhire, and appears very conſpicuous in Greenlane, over the incloſures to Narborough; it then coaleſces with the preſent turnpike, and continues with it till within the diſtance of four miles from Leiceſter, and croſſing a branch of the Soar at Langham bridge, it enters by the weſt gate of the town, the ancient ſtation Ratæ of the Itinerary. Leaving the county town, and going through Thurmaſton, it paſſes by a large oblong tumulus at Shipley hill to Syſton, and beyond Ratcliff proceeds over Thruſſington Wolds, which Higden termed the Waſtes, keeping near the verge of the diſtrict formerly called Churn wood, to Soxhill, where are another large tumulus, and the remains of an entrenched camp. Here it is viſible as a high ridge, which in many places is paved, or pitched with pebbles and other ſtones, and is interſected by a vicinal road, that connects it with the Hermine-ſtreet. Hence it proceeds to the ſtation Vernometum, near Willoughby in Nottinghamſhire; through this county it proceeds in a northerly direction over the Wolds, whence deviating a little to the north-eaſt it enters Bridgeford, the ſtation Mardunum of the ſixth and eighth iters; beyond which it is traceable on the weſt ſide of the preſent turnpike, in the incloſures called Eaſt-Bridgeford fields. Horſley, in his Britannia Romana, having fixed the ſtation Ad Pontem, near Southwell, carries the Foſs through that town. But the ſcite of this ſtation was more probably at or near Newark, by which, according to exiſting records, reſpecting alterations allowed to be made in the road, called in the charters, Via regia, the Foſs evidently paſſed. North of the town it is viſible, proceeding to North Collingham, where Gale and Stukeley fix the ſtation Crocolana, and Horſley at Brough in the immediate vicinity. Between this and Lindum, Lincoln, it is very conſpicuous; at which city, by ſome authors, the Foſs is ſuppoſed to terminate. But Dr. Bennet, biſhop of Cloyne, and the Rev. Mr. Lemon, who in the years 1778 and 9, travelled in queſt of the direction of the Foſs, from its commencement in Devonſhire, obſerve that it extends in a north-eaſterly direction from that ancient city by Burgh, on the ſmall river Bain, to Ludford, where they ſuppoſe was the ſtation Bannovallum. But this has every appearance of being only a vicinal way, and the road in queſtion more probably continued northerly on the line which they conſider forms part of the Hermine-ſtreet; an error which will be noticed in the deſcription of that road. In this point of bearing it proceeds to the ſtation Ad Abum at Wintringham, where by a ferry it croſſes the Humber. On this part of the line, which is ſtraight, the road is, in many places, particularly through the Woodlands, paved with flat-ſtones, ſet edge-wiſe in a ſtrong cement, and conſiderably raiſed; but over the heath it is formed of the uſual ſtrata. By the ferry of Ad Abum its progreſs was to the ſtation Delgovitia, at Wigton, whence it went to Eboracum, York. What was its exact direction, or how far beyond this ſtation it extended north, the reſearches of antiquaries have not been able to aſcertain. It is probable, that the termination was at the Picts wall; but equally improbable that it ever communicated with the ſhore of Caithneſs.

See Cotton MSS. in the Britiſh Muſeum; Leland's Itinerary; Stukeley's Itinerarium Curioſum; Horſley's Britannia; and the Beauties of England and Wales.

FOSSA, in *Anatomy*, a technical word, denoting ſuperficial cavities in the bones or other parts.

Fossa, in our *Ancient Cuſtoms*, was a ditch full of water, where women committing felony were drowned; as men were hanged. "Nam et ipſi in omnibus tenementis ſuis omnem ab antiquo legalem habuere juſtitiam, videlicet ferrum, foſſam, furcas, et ſimilia." In another ſenſe it is taken for a grave, as appears by theſe old verſes:

"Hic jacent in foſſa Bedæ venerabilis oſſa:
Hic eſt foſſatus, qui bis erat hic cathedratus."

Fossa, in *Geography*, a town of Italy, in the department of the Panaro; three miles N. of Mirandola.

Fossa *Clodia*, or *Claudia*, *Chiozza*, a town of Italy, in Venetia. Pliny.

Fossa *Nuova*, in *Geography*, a village and abbey of Italy, ſituated on the ruins of the little town of Forum Appii, mentioned in the Acts of the Apoſtles, and by Horace in his account of his journey to Brunduſium.

"—— Inde Forum Appii
Differtum Nautis, cauponibus atque malignis."

" To Forum Appii thence we ſteer, a place
Stuff'd with rank boatmen, and with vintners baſe."
Francis.

In the memoirs of St. Thomas Aquinas it is ſaid, that he was taken ill as he paſſed this way, and was carried to this convent, where he died. Legendary ſtory ſays, that his body was afterwards required by the king of France, and ordered to be carried to Thouloufe: but one of the monks, before the removal of the body, cut off the ſaint's head, and annexed another in its room: the true head was hid in the wall of the convent, and afterwards found, as the monkiſh fable reports, as freſh as the day when it was cut off, in conſequence of ſome ſcratching and knocking which occaſioned the walls being pulled down. Foſſa Nuova is two miles S. of Piperno.

FOSSAGLIO, a town of Italy, in the department of the Upper Po; five miles N. of Cremona.

FOSSANO, a town of France, in the department of the Stura, ſeated on the Stura, denominated, on account of its famous ſprings, "Fons Sanus," whence by corruption was formed Foſſano; erected into a biſhopric, under the archbiſhop of Turin in 1592, and taken by the French in 1796. Beſides the cathedral, it contains three pariſh churches, three convents, and about 900 inhabitants; five miles E. of Savigliano.

FOSSARII, in *Antiquity*, a kind of officers in the eaſtern church, whoſe buſineſs was to inter the dead.

Ciaconius relates that Conſtantine created 950 foſſaries, whom he took out of the divers colleges or companies of tradeſmen: he adds, that they were exempted from taxes, ſervices, burthenſome offices, &c.

F. Goar, in his notes on the Greek Euchologion, inſinuates that the foſſarii were eſtabliſhed in the times of the apoſtles; and that the young men who carried off the body of Ananias, and thoſe perſons full of the fear of God, who interred St. Stephen, were of the number.

St. Jerom aſſures us, that the rank of foſſarii held the firſt place among the clerks; but he is to be underſtood of thoſe clerks only who had the direction and intendance of the interment of the devout.

FOSSAT, in *Geography*, a town of France, and chief place of a canton in the department of the Arriege, and diſtrict of Mirepoix; 21 miles W. of Mirepoix. The town contains 889, and the canton 9578 inhabitants, on an extent of 170 kiliometres, and in 10 communes.

FOSSE, Charles La, in *Biography*, a painter of hiſtory and landſcape of great celebrity in France, but not very juſtly entitled to his fame; as may be ſeen by one of his works now on a cieling at the Britiſh Muſeum, painted originally at the command of Ralph, duke of Montagu, in the reign of James II.

He was born at Paris in 1640, and was a diſciple of Le Brun; but was afterwards ſent by Louis XIV. to ſtudy in Italy. He formed his taſte more upon the Venetian than the Roman ſtyle; for which reaſon his works have far leſs of correctneſs in drawing, than richneſs of colour; and by this means, perhaps, he obtained a good reputation, when more ſkilful men, whoſe talents were directed to higher objects, would have been neglected. We have particularized him here becauſe he was the artiſt employed to decorate Verſailles, Trianon, Marly, and the palaces of many of the nobility of France, when it was the faſhion to load ſtaircaſes and cielings with abſurd allegories and taſteleſs compoſitions of groteſque ſcenery. La Foſſe died in 1716, aged 76.

Fosse, Anthony de la, was born at Paris in 1653. He devoted himſelf to polite literature, and obtained conſiderable reputation as an author. He is known alſo in the political world as ſecretary to the marquis de Crequi in the war in Italy, and after this to the duke d'Aumont in his government of the Bolonnois. He wrote Italian with the utmoſt facility, and ſo well, that for an ode, which he compoſed in the language, he was received into the Academy Degli Apatiſti at Florence. His chief literary compoſitions were tragedies, ſeveral of which, particularly that entitled "Manlius Capitolinus," were ſucceſsful on the ſtage. He tranſlated, or rather paraphraſed, Anacreon, which was publiſhed with ſome miſcellaneous poetry in the year 1704. He died in 1708. His works were publiſhed in two vols. 12mo. in 1755. The verſes of La Foſſe are extremely laboured, and are ſaid to have coſt him more pains in expreſſion than in the thought. Moreri.

Fosse, in *Gardening*, is a ſort of ſunk fence, large ditch, or *ha-ha*, made on the outſides or boundaries of ornamented grounds, in order to extend the proſpect in an uninterrupted manner. Fences of this nature are formed of different depths and breadths, according to circumſtances; but ſix or ſeven feet in depth, and ten or fifteen in width, are the moſt common. Where the extent of pleaſure-ground is inconſiderable, theſe fences give the particular parts of the garden or grounds an air of larger extent than they really poſſeſs; as at a diſtance nothing of them is ſeen, ſo that the adjacent fields, &c. appear to be connected with them: where the pleaſure-ground is ſituated near to a park, paddock, or any ſpacious field open to an agreeable proſpect, they are often continued round, as far as they are agreeable, from the walks of the pleaſure-grounds or other garden grounds.

Works of this kind are formed in different ways, but always ſo as to ſerve the purpoſe of fences, and afford an uninterrupted view of the whole extent of the ground.

One method of conſtructing them is with an upright ſide next the garden or pleaſure-ground, or in the contrary direction, according to circumſtances and ſituation, five, ſix, or ſeven feet deep, faced with a wall of brick, ſtone, or ſtrong poſt and planking; the other ſide being made ſloping outward from the bottom of the upright wall, &c. gradually, with an eaſy ſlope of fifteen or twenty feet diſtance, or more, ſo as to render the declivity as eaſy and imperceptible as poſſible, both to take off all ſtiff and ditch-like appearance, and that when in a field or park, no ground may be loſt from its being capable of being converted into graſs. The top of the upright ſide ſhould be made nearly upon a level with the adjacent pleaſure-ground, and always a little higher than the top of the ſlope on the oppoſite ſide, being laid with graſs correſponding to the adjoining garden or pleaſure-ground; unleſs it be thought convenient to continue a gravel-walk that way; in which caſe, a proper verge of graſs ſhould conſtantly be preſerved between the walk and the edge of the foſſe; the ſlope ſide ſhould alſo have its top always nearly on a level with the adjacent ground of the field, park, or part where it is formed; and the ſide finiſhed with a regular ſlope from top to bottom, being alſo ſown or laid down in graſs, which will always preſerve the ſlope in due form, and have an agreeable appearance to the ſight at all ſeaſons.

Where in forming this kind of foſſe, by reaſon of water it cannot be got deep enough to form the upright ſufficiently as a fence, a *chevaux de friſe* of wood-work may be erected along the top, projecting outward in a nearly horizontal poſition, or as much ſo as to riſe but very little above the level of the top of the perpendicular ſide on which it is fixed, that it may not obſtruct the view, or be very

perceptible from the garden or pleaſure-ground, which it is intended to improve.

There is another fence of this ſort which is formed with both ſides ſloping, and in perpendicular depth from four to five or ſix feet, having a fence near that height arranged along the bottom; the ſides being ſloped gradually from the bottom to ten or twenty feet width, or more at top; as the more eaſy and imperceptible the ſlope the better, particularly on the field-ſide. The ſides muſt be ſown or laid with graſs. In this, as both ſides are ſloped, a fence along the bottom is neceſſary as a defence againſt cattle, &c. which may be either ſtrong paling, or any kind of paliſado-work, the height in proportion to the perpendicular depth of the ſunk fence, as the top ſhould not be higher than that of the ſlopes in ſuch caſes.

It is uſual, in conſtructing the firſt ſort of fences of this nature, to begin by ſetting out the intended width by two ranges of ſhort ſtakes; then to level in the ſtakes by notching, according to the intended height of the top on each ſide, correſponding with the adjacent ground, making up both the top lines with earth firmly, according to the line of level marked on the ſtakes; then, cloſe along the ſide of the line of the intended upright ſide, proceeding to dig a trench three feet wide, perpendicularly to the intended depth; and as the labour goes on to work alſo the ſloping-ſide gradually down, ſtill continuing digging the trench perpendicularly next the garden, &c. till arrived at the proper depth: when it is neceſſary to level the bottom equally along according to the lines of level at top; and having proceeded ſo far, then, according to the line of level at top and bottom, to trim and finiſh off the ſloping ſide regularly, ſo as to form an even ſlope from the outſide line at top to that at bottom: as to the upright ſide, a wall muſt be erected to the height of the line of level at top, making good the ground behind the wall firmly as the building advances, and finiſhing the top with a coat of turf, level with the adjoining ground; at the ſame time alſo finiſhing the ſlope, either by ſowing it with graſs-ſeeds, or laying it with turf, as may be the moſt convenient in the particular circumſtances.

But in forming the ſecond ſort of foſſe, it is directed to ſet out the width by two lines of ſtakes; then to level them in, and make up the ground of each line according to the mark of level, as before; thus, exactly along the middle, between the two lines of ſtakes, to dig a trench two or three feet wide, to the intended depth of the fence, ſloping each ſide a little as the work goes on, ſtill continuing the trench perpendicularly, till arrived at the due depth; then, as in the former caſe, to level the bottom to an equal depth by ſtakes, agreeable to the lines of level at top: when this is effected, finiſh off both ſlopes evenly from each line of level at top to that at bottom, and ſow each ſlope with graſs-ſeeds, or lay them with turf, as moſt proper. The fence along the bottom may be either cloſe-paling, rails, or paliſadoes, as moſt convenient; the height proportionable to the depth of the foſſe, but not higher, or at leaſt but very little, than the line of level at the top of the foſſe.

In the execution of the work in both caſes the internal materials ſhould be well trodden down, or rammed in, in order that the whole may be rendered perfectly ſolid, and prevented from ſinking irregularly and being thrown down.

FOSSENET, in *Geography*, a town of France, in the department of the Upper Garonne; 7 miles W. of Rieux.

FOSSES, a town of France, in the department of the Sombre and Meuſe, and chief place of a canton in the diſtrict of Namur, ſituated between the Sombre and the Meuſe; 7 miles W. of Namur. The town contains 1574, and the canton 13,780 inhabitants, on a territory of 270 kiliometres, and in 25 communes.

FOSSETA, a town of Italy, in the Treviſan; 12 miles E.S.E. of Trevigio.

FOSSILS, in *Mineralogy* and *Geology*, a term which, in its ſtrict and uſual ſignification, is ſynonymous with that of *mineral*; being applied to the inorganic bodies that are formed in, and at the ſurface of the earth, according to phyſical and chemical laws. (See MINERALS.) The French, we ſuppoſe, were the firſt who diſtinguiſhed by this appellation thoſe animal and vegetable remains that, owing to particular circumſtances, inſtead of decaying when buried in the earth, have more or leſs preſerved their original form and ſtructure, and are found penetrated by, or even converted into, ſubſtances belonging to the mineral kingdom. Theſe ſubſtances, before their natural hiſtory began to be elucidated, were denominated *lapides idiomorphi*, *figurati*, *diluviani*, &c.; but ſuch names ſoon gave way to that of *petrifacta*, or *petrifactions*, which was adopted in almoſt all languages. In latter times, however, the denominations *extraneous* or *adventitious foſſils*, propoſed for this order of natural bodies by ſir John Hill, have been revived by ſome authors. Mr. Parkinſon, conſidering the word "petrifactions" inadmiſſible as a general term, recommends the appellation of "ſecondary foſſils," while "primary foſſils" are to him thoſe ſubſtances which are ſuppoſed to be natives of, and to have exiſted primitively in, the ſubterranean regions. Mr. Martin, in his "Outlines," prefers the terms *reliquium* and *reliquia* (which ſhould be *reliquiæ*). But neither of them appearing ſatisfactory, we ſhall, in this work, retain the old appellation *petrifactions*; to which we refer the reader for a hiſtory of the ſubſtances in queſtion: for though we are aware that its etymology refers only to a converſion into ſtone, yet in this, as in many other caſes, recourſe muſt be had to the well known rule *a potiore fit denominatio*. And, indeed, even thoſe writers who reject the word "petrifactions" as not ſufficiently general, retain another of the ſame import in all the generic names of the extraneous foſſils, ſuch as ornitho*lithus*, ichthio*lithus*, helmintho*lithus*, &c.

FOSSIL-*plant*. See PLANT.

FOSSILS, *Marine*. See MARINE.

FOSSIL-*ivory*. See IVORY.

FOSSIL-*ſalt*. See SALT.

FOSSIL-*wood*. See WOOD.

FOSSIL *Coal*, in *Agriculture*, an inflammable ſubſtance which is ſaid to be capable of being rendered ſoluble by ſaline ſubſtances, in which ſtate it may probably be found beneficial to the farmer.

FOSSIL *Manure*, is that ſort which is of a foſſile nature, and which is raiſed from the bowels of the earth. Lime, marle, and other ſimilar ſubſtances, are moſtly conſidered as of the foſſil kind by writers on huſbandry.

FOSSOMBRONE, in *Geography*, a town of Italy, in the duchy of Urbino, ſeated on the Metro; the ſee of a biſhop, ſuffragan of Urbino; erected out of the ruins of Forum Sempronii, which was deſtroyed by the Goths and Lombards; 10 miles S.E. of Urbino. N. lat. 43° 42′. E. long. 12° 44′.

FOSSORES, in *Natural Hiſtory*, a name given to a ſpecies of ſmall worms hatched from the eggs of a fly, which feeds on the parenchymatous ſubſtance of the leaves of plants, burying themſelves between the two membranes. Theſe animals in general are called by Reaumur aſcarides,

but as they greatly differ in their ſize, and in their manner of eating and deſtroying leaves, the ſmall ones, which eat but ſlowly, and gnaw their way in crooked furrows, are called by him foſſores parvi; and on the contrary, thoſe which eat away all that lies before them, and are of a ſomewhat larger ſize, are called foſſores magni. See ASCARIDES.

FOSSUM, in *Geography*, a town of Norway, in the dioceſe of Aggerhuus; 23 miles W. of Chriſtiania.

FOSTA, a town of Sweden, in the province of Smaland; 21 miles E. of Upſal.

FOSTAL, in *Agriculture*, is a term ſignifying the way that leads from the main road to a farm-houſe.

FOSTAT, called alſo *Maſr* and *Maſr-el-Atik*, and by the Venetian merchants, and ſome modern travellers, *Old Cairo*, in *Geography*, a town of Egypt, ſituated between Grand Cairo and the Nile, about half a league from Boulac. In the 20th year of the Hegira, ſays Elmacin in his hiſtory of the Arabs, Amron, ſon of Eleas, built Maſr Foſtat on the ſpot where he had formed his camp, previouſly to his beſieging Alexandria. The general, on his return from his conqueſts, laid the foundation of a town there, to which he gave the name of "Foſtat," ſignifying in Arabic "tent." Afterwards the governors ſent by the caliphs made it their place of reſidence. It took the ſurname of "Maſr" as it is ſaid, from Mizraim, the ſon of Ham, who ſettled in Egypt; a name which Memphis had borne before, and which the Arabs always beſtow on the capital of Egypt. Its ſituation on the banks of the Nile, and near a canal that communicated with the Red ſea, rendered it in a ſhort time very flouriſhing. It was about two leagues in circumference, when Schaouar, 500 years after its foundation, delivered it up to the flames, in order to prevent its falling under the dominion of the French. Its power terminated with this epocha. With its inhabitants, it loſt its commerce and its riches. It was then that Grand Cairo, having become the reſidence of the grandees and the kings of the country, received the pompous epithet of Maſr; and that Foſtat aſſumed that of El-Atik, which ſignifies "the ancient," and which it bears at this day. Maſr-el-Atik is not now half a league in circumference; but it is ſtill very populous, and has conſiderable trade. This town indicates the ſcite of the Babylon of Egypt; and it is the port for the boats that come down from the Said, or Upper Egypt, as Boulac is that of the Delta. Here, in the midſt of the Mahometan moſques, the Jews have a ſynagogue, and the Catholics a convent and a church; but the Copts have reſerved to themſelves that which is reckoned by the devout the moſt precious ſpot: this is a grotto, or low chapel, in which, according to tradition, the virgin lived ſome time with the infant Jeſus, when they were obliged to flee into Egypt. This tradition is a ſource of profit to the Copts, who charge fees for admiſſion into this chapel. At Old Cairo are to be ſeen Joſeph's granaries, if this appellation may be given to a large ſpace of ground, ſurrounded by walls 20 feet high, and divided into courts without any roof or covering; in which is depoſited the corn brought from Upper Egypt as the fiſcal duties, and where it becomes the food of a multitude of birds, and the receptacle of their dung. The walls are badly conſtructed; nor has this building any appearance of antiquity, ſo that nothing but the love of the marvellous could have attributed the erection of it to the patriarch Joſeph. Another work of the Arabs, which is remarkable for the boldneſs as well as the beauty of its conſtruction, and the only one worth ſeeing in the ancient city of Cairo, is the aqueduct that conveys the water of the Nile into the caſtle. It is ſupported by 350 narrow and very lofty arcades. The water is raiſed by a chain-pump with four wheels, which is worked by oxen. In front of Old Cairo the Nile leaves, in the middle of its bed, an iſland of about five hundred yards in breadth, where is built the "mekkias," ſignifying Meaſure. See NILOMETER. At the extremity of Maſr-el-Atik, near the water-caſtle, commences the khalig or canal, which traverſes Grand Cairo. See CAIRO.

FOSTER, JAMES, in *Biography*, a celebrated preacher, was born at Exeter in the year 1697, where he was educated; and ſo great was his progreſs, that the maſter of the ſchool boaſted of him as his moſt promiſing pupil; from the grammar ſchool he was ſent to an academy for educating diſſenting miniſters, then under the ſuperintendance of Mr. Joſeph Hallet, where, by his abilities, induſtry, and improvement, he quickly acquired the admiration of his tutor and fellow ſtudents. He commenced public preacher in the year 1718, and was ſoon diſtinguiſhed among his brethren for popular talents. At this period, debates among the diſſenters in the weſt of England ran high reſpecting the doctrine of the trinity and ſubſcription to certain teſts of faith. Mr. Foſter took the liberal ſide of the queſtion: he ſcorned to dogmatize over the creeds of other men, and would not ſuffer the tenets of others to be impoſed on him; a clamour was excited, and he judged it prudent to remove to ſome other ſcene. His firſt ſettlement as miniſter was with a congregation at Milbourne-port, Somerſetſhire, where he remained till the zealots among his own people rendered the ſituation uneaſy, perhaps, even unſafe, and he accordingly removed to the houſe of a brother miniſter in an obſcure retreat under the hills of Mendip in the ſame county. Here he preached to two congregations, who were ſo poor, that, together, they could not raiſe their miniſter 15*l.* *per annum*. Mr. Foſter was, however, content to remain in obſcurity, and in want of the comforts of life, provided he could enjoy the ſatisfaction which aroſe from his integrity. He found abundant reſources in his own mind, and, though without any proſpects of extended uſefulneſs, applied himſelf to the ſtudies of his profeſſion with an almoſt unremitted appplication. In the year 1720 Mr. Foſter publiſhed "An Eſſay on Fundamentals, with a particular regard to the doctrine of the ever-bleſſed Trinity," &c. To this eſſay he ſubjoined a ſermon, entitled "The reſurrection of Chriſt," proved and vindicated againſt the moſt important objections of the ancient Jews, or modern deiſts, and his diſciples ſhewn to be ſufficient witneſſes of the fact. From Aſhwick Mr. Foſter removed to Trowbridge, in Wiltſhire, where he preached to a very ſmall congregation; and during his reſidence at this place he became a convert to adult baptiſm by immerſion, and accordingly ſubmitted to that rite in London as ſoon as an opportunity offered. This ſtep produced no difference between him and his congregation at Trowbridge; ſo ſmall, however, was his income, and, probably diſheartened at the paucity of his attendants, that he entertained ſerious thoughts of quitting the miniſtry, and betaking himſelf to ſome ſecular employment. While deliberating on the future courſe of his life, he unexpectedly met with a patron and friend in Robert Houlſton, eſq. who appointed him his domeſtic chaplain, and treated him with the utmoſt kindneſs and generoſity. In 1724 he was invited to ſucceed Dr. Gale at the baptiſt congregation in Barbican: he accepted the offer, and continued to officiate as their miniſter upwards of twenty years. In 1728 he opened a Sunday evening lecture in the Old Jewry, which he carried on almoſt to his death with an unexampled degree of popularity. Here he was attended by crowds of perſons of all ranks, ſtations, and qualities. In the year 1744 he was choſen

choſen to ſucceed Dr. Hunt at Pinners' hall; and in 1748 the degree of doctor of divinity was conferred upon him by the college of Aberdeen in the handſomeſt way. The college, by means of their principal, ſaid in a letter to Mr. Foſter, "We beg that you will be ſo good as to accept the diploma as a ſmall mark of the veneration we have for you, and of the ſenſe we entertain of the eminent ſervices you have done to the cauſe of liberty, religion, and virtue, by your writings as well as inſtructions." In 1750, Dr. Foſter was afflicted by a violent diſorder, from the effects of which he never compleatly recovered, though he continued to preach till the beginning of the year 1752, when he was attacked by a paralyſis, which was repeated in October, and on the 5th of the following month he died, in the fifty-fifth year of his age. The works of Dr. Foſter, to which the univerſity in their letter referred, are, 1. His treatiſe on "The Uſefulneſs, Truth, and Excellency of the Chriſtian Revelation, &c." in anſwer to a book entitled "Chriſtianity as old as the Creation." 2. Several volumes of ſermons on important and intereſting ſubjects. After this, *viz.* in 1749, Dr. Foſter publiſhed in quarto the firſt volume of his "Diſcourſes on all the Principal Branches of Natural and Social Virtue." The ſecond volume of this work was printed in 1752. Beſides theſe, he publiſhed ſome ſingle ſermons; and "An Account of the behaviour of the late earl of Kilmarnock, after his Sentence and on the Day of his Execution." He had attended this unfortunate nobleman during his impriſonment, and could ſpeak, from his own knowledge, as to the facts ſtated in the publication. On the death of Dr. Foſter, as well as during his life, the moſt unexceptionable teſtimonies were borne to the excellence of his character, and to his great talents as a preacher. The lines by Pope are well known.

"Let modeſt Foſter, if he will, excel
Ten metropolitans in preaching well."

Thoſe taken from the Gentleman's Magazine, and ſuppoſed to have been written by Savage, are equally characteriſtic and more full.

"But ſee th' accompliſhed orator appear,
Refined his language, and his reaſoning clear;
Thou only, Foſter, haſt the pleaſing art,
At once to charm the ear and mend the heart."

Mr. Rider, afterwards maſter of St. Paul's ſchool, and known by ſeveral uſeful publications, ſpeaking of Dr. Foſter, ſays "His voice was naturally ſweet, ſtrong, diſtinct, harmonious, always adapted to his matter, always varied as his method changed, as expreſſive of the ſenſe as the moſt judicious recitative. Monotony was a fault of which he was never guilty. His action, the ſoul of eloquence, was grave, expreſſive, free from diſtortions, animated without being theatrical; in ſhort ſuch as became the pulpit. He reminded us of Paul at Athens, arreſting the attention of his auditors." He uſed no deluſive arts to bribe the paſſions, to play with the imagination, and ſo impoſe on the underſtanding. He had no ambiguities, no diſguiſes; but, whatever he thought an important truth, he delivered with freedom and without reſerve. In private life he was diſtinguiſhed for candour and liberality, integrity and modeſty, great tenderneſs and benevolence of diſpoſition, and unaffected ardent piety. Gen. Biog. Britiſh Biog.

Foster, John, was born at Windſor, and received his grammatical and claſſical education at Eton, where he acquired a decided ſuperiority over his contemporaries. From Eton he went to King's college Cambridge, of which ſociety he became fellow in 1748. He was afterwards an aſſiſtant to Dr. Barnard maſter of Eton ſchool, and in 1765 obtained the ſame office himſelf. But finding his temper and manners ill adapted to the ſituation, he reſigned it, though not till his health had been much injured by the vexations which he had experienced. He was preſented to a canonry of Windſor in 1772, and in the following year, he viſited the German Spa for the recovery of his health. Here he died and was buried in the month of September. He is known to the learned world by "An eſſay on the different nature of accent and quantity, with their uſe and application in the pronunciation of the Engliſh, Latin, and Greek languages; containing an account and explanation of the ancient tones, and a defence of the preſent ſyſtem of Greek accentual marks." To this eſſay was annexed the Greek poem of Muſurus, addreſſed to Leo. X. with an elegant Latin verſion. He printed likewiſe a prize diſſertation pronounced at Cambridge in 1754, with the title of "Enarratio et Comparatio Doctrinarum Moralium Epicuri et Stoicorum."

Foster, *Sir* Michael, an eminent lawyer, was born in 1689, at Marlborough in Wiltſhire, where he received the early parts of his education, and from whence, in 1705, he was removed to Exeter college, Oxford. He purſued his profeſſional ſtudies in the Middle Temple, and was in due time called to the bar. Not meeting with that ſucceſs which he anticipated in the courts of law, he ſettled firſt at Marlborough, and then, having married, he removed to Briſtol, where he practiſed in his profeſſion with much reputation. He was choſen recorder of the city in 1735, and in the following year he was called to the degree of ſerjeant at law. About this period he publiſhed a pamphlet entitled, "An examination of the ſcheme of the church power laid down in the Codex Juris Eccleſ. Anglicani," which was regarded by the friends to the principles of the Britiſh conſtitution, as an important barrier againſt the doctrines contained in biſhop Gibſon's work. The controverſy excited much attention, and Mr. Foſter's work was read and greatly admired by one party, and oppoſed and anſwered by the other. In 1745, by the recommendation of lord chancellor Hardwicke, Mr. Foſter was made one of the judges of the court of king's bench, with the honour of knighthood. In 1762, he publiſhed "A report of ſome proceedings on the commiſſion for the trial of the rebels in the year 1746, in the county of Surrey; and of other crown caſes, to which are added diſcourſes upon a few branches of the crown law." This work is of the very firſt order, and was abundantly ſufficient to perpetuate the name of the author, who is ſtyled by ſir William Blackſtone, "a very great maſter of the crown law." It has been twice reprinted with valuable additions by his nephew, the late Mr. Michael Dodſon. The health of judge Foſter began to decline almoſt immediately on the death of his lady in 1758; but his life was lengthened out till November 7th, 1763. He was beloved in private life and reſpected by all who knew him. As a judge he maintained his ſtation with great credit for legal knowledge and integrity, during a period of eighteen years, which were marked with the deciſion of many points of ſingular importance in civil and criminal law. He was looked up to as one of thoſe judges who beſt ſuſtained that ſpirit of independence and regard to the rights of the ſubject, which it is the boaſt of Engliſh juriſprudence to have ſecured upon the bench, but which are not unfrequently ſhackled in their exertions, by the purſuit of court favour. See the article Dodson: and Gen. Biog.

Foster, Samuel, an Engliſh mathematician, born in North-

Northamptonſhire, was educated at Cambridge, where he took his degree of maſter of arts. In 1636 he was choſen profeſſor of aſtronomy, in Greſham college, which, however, he reſigned at the cloſe of the ſame year; but in 1641, he was re-elected to the ſame office, and retained it during his life. He was one of the inſtitutors of the ſociety, which met to cultivate the new philoſophy and uſeful knowledge, and which it ſhould ſeem, was eſtabliſhed for the ſake of diverting the minds of the thoughtful from the diſputes, which at that period divided the country with reſpect to religion and politics. This was the foundation of the Royal Society, to which the ſcientific world is under the greateſt obligations. Mr. Foſter died at Greſham college, in the year 1652. He was the author of ſeveral mathematical pieces, of which the principal are, "The art of dialling:" "Deſcription of ſundry inſtruments invented or improved by himſelf." His "Uſe of the Quadrant, &c." firſt appeared as an appendix to Gunter's deſcription of the Croſs-ſtaff. The greater part of his works were republiſhed after his death, carefully corrected by his friends Dr. Twyſden and Mr. Edmund Wingate. In the ſame century there were two other Foſters diſtinguiſhed as mathematicians, *viz.* William, a pupil of Oughtred, and author of "The circles of proportion and the horizontal inſtrument:" and Mark Foſter, who publiſhed a treatiſe entitled "An Arithmetical Trigonometry by common arithmetic, without the uſe of Tables, &c." Ward's lives of the profeſſors of Greſham college.

FOSTER, in *Geography*, a townſhip of America, in Providence county, Rhode iſland, containing 2457 inhabitants; 17 miles W. of Providence, and 31 N. W. of Newport.

FOSTER-LAND, a term employed by our *Old Writers* to ſignify the land given or allotted for the finding of food or victuals; as for monks in certain monaſteries or religious houſes.

FOSTERLEAN, anciently ſignified nuptial gifts; much the ſame with what we now call *jointure*.

The word is originally Saxon, and ſignifies *ciborum exhibitio*, that is, a ſtipend which the wife has for her maintenance. "Poſtea ſciendum eſt cui foſterlean pertineat, vadiet hoc Brigdunia, & plegient amici ſui."

FOTHER. See FODDER *of lead*.

FOTHERGILL, JOHN, in *Biography*, an eminent phyſician, was born at Carrend, in the county of York, on the eighth of March 1712, of reſpectable parents, who were members of the ſociety of quakers. He was in his childhood placed under the care of his maternal grandfather, who ſent him at a proper age to the grammar ſchool of Frodſham, in Cheſhire, where he reſided. At this ſchool he continued till his twelfth year, and was then removed to another at Sedberg, in Yorkſhire, where he remained about four years, and obtained a competent knowledge of the Latin language, and ſome acquaintance with the Greek; and although, as he himſelf has been heard to acknowledge, he was not careful enough to improve the latter; yet he continued, after he left theſe ſchools, to cultivate his Latinity, ſo as to read authors in that language very familiarly, and to write in it with ſufficient fluency. But his attention was directed rather to general knowledge, than to the ſtudy of the learned languages, which he regarded little farther than as the vehicles of profitable information. About the year 1728, he was apprenticed to Benjamin Bartlett, a very reputable and intelligent quaker apothecary, at Bradford in Yorkſhire, who had previouſly been the tutor of Dr. Hillary. After the completion of his apprenticeſhip he removed to Edinburgh, where he purſued his ſtudies with diligence, and graduated on the 13th of Auguſt, 1736. He then entered himſelf a phyſician's pupil at St. Thomas's hoſpital in London, the practice of which he attended for two years. After a ſhort excurſion to the continent with a few friends, in the ſpring of 1740, he returned to London, and took up his reſidence in White-hart court, Gracechurch ſtreet, where he continued during the greater part of his life, and where he acquired and eſtabliſhed both his fame and his fortune. His practice for ſome years was confined chiefly to the lower claſs of people, ſo that he has often traverſed the outſkirts of the city from morning till night, and returned home without having taken one fee. In 1746, he was admitted a licentiate of the College of Phyſicians; and in 1748, he publiſhed his "Account of the putrid ſore Throat;" a work, which is ſtill highly eſteemed as an able ſpecimen of medical hiſtory, which has been tranſlated into almoſt every European language, and to which he owed a conſiderable extenſion of his practice. He was now introduced into the firſt families in the metropolis; and was ſeldom employed where he was not ſought for again on ſimilar emergencies.

In 1754, Dr. Fothergill was elected a fellow of the College of Phyſicians at Edinburgh, and in 1763, a ſimilar honour was conferred upon him by the Royal Society of London, to whom he had, ſeveral years before, communicated ſome intereſting papers, which were inſerted in different volumes of their Tranſactions. Theſe were not the only academical honours which his great merits procured for him. He was one of the earlieſt members of the American Philoſophical Society; and in 1776, when a Royal Medical Society was inſtituted at Paris, Dr. Fothergill was one of a ſelect number of foreign phyſicians, whom the ſociety thought proper to rank among their aſſociates.

Dr. Fothergill had very early acquired a taſte for botany, which he indulged in proportion as the profits of his practice increaſed. For this purpoſe he purchaſed an eſtate at Upton, in Eſſex, containing, beſides other lands, between five and ſix acres of garden-ground. In this place, at an expence ſeldom undertaken by an individual, and with an ardour that was viſible in the whole of his conduct, he procured from all parts of the world a great number of the rareſt plants, and protected them in the moſt ample buildings which this or any other country has ſeen. In a word, every plant that ſeemed likely to be uſeful in medicine or manufactures, or was admirable from its beauty or rarity, was to be found in his garden; and his ſuite of hot and green-houſe apartments, of nearly 260 feet in length, contained upwards of 3,400 ſpecies of exotics, and in the open ground were about 3000 other ſpecies of plants and ſhrubs. In compliment to his zeal and abilities the celebrated Linnæus diſtinguiſhed a plant of the claſs Polyandria Digynia by the name of *Fothergilla*. But the exertions of Dr. Fothergill were not confined to botany; he ſtudied the other departments of natural hiſtory, and patronized its ingenious cultivators. He had a very accurate knowledge of conchology, and poſſeſſed the beſt cabinet of ſhells in the kingdom, with the exception of that of the ducheſs of Portland; his collection of ores and minerals was diſtinguiſhed for the rarity, rather than the number of the ſpecimens that compoſed it; his cabinet of inſects was extremely elegant, and it was from his collection of corals that the ingenious Mr. Ellis delineated his ſyſtem. The great botanical work by Miller was begun and finiſhed under the patronage of Dr. Fothergill, to whom it was with great propriety inſcribed. But the dedication was afterwards cancelled, at his expreſs ſolicitation; for although he took pleaſure in encouraging ingenuity, he diſliked to be told of it; and indeed he was averſe to dedications in general, conſidering

ſidering them as a ſpecies of literary pageantry, more productive of envy to the patron, than of advantage to the author.

In the conteſts between the fellows and licentiates of the College of Phyſicians Dr. Fothergill took an active part, and ſubſcribed five hundred pounds towards bringing it to a legal deciſion. But he was not content with exerting his talents for the benefit of ſcience and of his profeſſion: his benevolence prompted him to many other labours. His obſervations on the ſubjects of police, we are told, could they be collected together, would conſtitute an ample and uſeful volume. (See Dr. Lettſom's Life of Dr. F.) He is ſaid to have written nearly an hundred letters in the Gazetteer on the ſubject of the new pavement; and he was inceſſantly communicating uſeful hints for the improvement of this great city. It was he who firſt ſuggeſted the plan of bringing fiſh by land carriage, in order to break a monopoly, which had highly enhanced the price of freſh fiſh in all the markets about London. At the approach of the ſevere winter of 1767, he propoſed a ſcheme, and liberally contributed to raiſe a fund for the purpoſe, of purchaſing fiſh at a wholeſale cheap price, and of diſpoſing of it at a ſmall loſs, till the whole ſubſcription ſhould be expended. The ſociety, who ſupported the meaſure, which was continued till 1770, in the ſame manner purchaſed potatoes in Lancaſhire, and conveyed them by water to the metropolis. But the inſtitution of the ſeminary at Ackworth, in Yorkſhire, of which he was the projector in 1778, and to which he was a liberal benefactor, both during his lifetime and by his will, was one of the moſt important plans which his zeal to promote the welfare of ſociety led him to undertake. Of his kindneſs and bounty to individuals it will be ſufficient to mention one inſtance, in the caſe of his worthy but unfortunate friend, the late Dr. Gowin Knight; who applied to Dr. Fothergill in a moment of pecuniary diſtreſs, and returned with a heart ſet at eaſe by the noble benefaction of a *thouſand guineas*.

Finding his pleaſant retreat at Upton too remote to be often viſited, while engaged in his profeſſion, and yet too much within the ſphere of action to be a refuge from care and importunity, Dr. Fothergill procured a leaſe of Lea-Hall, near Middlewich in Cheſhire, in the ſummer of 1765, to which ſecluded ſpot he afterwards made an annual retreat as long as he lived; commonly leaving London in the month of July, and returning in the beginning of October. This retreat became the more neceſſary, when, in 1767, he removed to Harpur ſtreet, and enlarged the circle of his practice. For the greater part of his life he had enjoyed good health. But in November 1778, he was afflicted with a diſorder, which he apprehended, though without foundation, to be an irregular gout: it terminated in a ſuppreſſion of urine, from which he recovered in about three weeks, and for the ſpace of two years enjoyed his wonted degree of health. But the time was now approaching, when he was to experience that neither temperance nor medical ſkill could exempt him from the final lot of humanity. On the 12th of December 1780, he was again ſeized with a ſuppreſſion of urine, which, notwithſtanding every effort of the experienced phyſicians and ſurgeon, who attended him, terminated his life on the 26th day of the ſame month. On diſſection the diſeaſe appeared to have been occaſioned by a ſcirrhous enlargement of the proſtate gland, which compreſſed the neck of the bladder, ſo as to prevent the introduction of a catheter. His remains were depoſited in the quakers' burial ground at Winchmore-hill, about twelve miles from London.

The perſon of Dr. Fothergill was of a delicate rather than an extenuated make. His features were all expreſſive, and his eye had a peculiar brilliancy. His underſtanding was comprehenſive and quick, and rarely embarraſſed on the moſt ſudden occaſions. There was a charm in his converſation and addreſs that conciliated the regard and confidence of all who employed him, and ſo diſcreet and uniform was his conduct, that he was not apt to forfeit the eſteem which he had once acquired. At his meals he was uncommonly abſtemious, eating ſparingly, and rarely exceeding two glaſſes of wine at dinner or ſupper. By this uniform and ſteady temperance, he preſerved his mind vigorous and active, and his conſtitution equal to all his engagements.

Dr. Fothergill's writings, with the exception of his inaugural theſis "De Emeticorum Uſu" (which is preſerved in Smellie's "Theſaurus"), and his "Account of the putrid ſore-throat," conſiſt principally of papers printed in the Philoſophical Tranſactions of the Royal Society, and in the "Medical Obſervations and Inquiries," a work of which ſix volumes were publiſhed, and which is known and highly eſteemed wherever medical ſcience is ſucceſsfully cultivated. Beſides the numerous eſſays in this excellent collection, to which the name of Dr. Fothergill is prefixed, we learn that he was the author of the three anonymous papers in the fourth volume, which conſtitute the 8th, 10th, and 17th articles. He alſo publiſhed ſeveral little eſſays, on the weather and reigning diſeaſes, on the Simarouba, and other ſubjects, in the Gentleman's Magazine, and other periodical publications, which, however, were written in haſte and not publicly avowed. Theſe works have been collected and reprinted by Dr. Elliott, in 8vo. 1781, and by Dr. Lettſom in 4to in 1784. See Dr. Hird's affectionate tribute, &c. Dr. Elliott's Life of Dr. F.; Dr. Lettſom's Account of Dr. F.; and Dr. Thompſon's Life of Dr. Fothergill; alſo Lond. Med. Journal, vol. iv. p. 176.

FOTHERGILLA, in *Botany*, juſtly ſerves to commemorate the late John Fothergill, M.D. F.R.S. who, though not a writer on Botany, was eminently uſeful to the ſcience, by introducing a great number of new plants, chiefly from the alps of Europe and from America, which he cultivated with ſucceſs in his garden at Upton, and readily communicated to his friends.—Linn. Suppl. 42. Ait. Hort. Kew. v. 2. 241. Schreb. 922. Willd. Sp. Pl. v. 2. 1224. Mart. Mill. Dict. v. 2. Juſſ. 408. Claſs and order, *Polyandria Digynia*. Nat. Ord. *Amentaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, bell-ſhaped, cloſe, ſhort, truncated, permanent. *Cor.* none. *Stam.* Filaments numerous, thread-ſhaped, thickened upwards, much longer than the calyx; anthers minute, erect, quadrangular. *Piſt.* Germens two, combined, ovate; ſtyles two, awl-ſhaped, terminal, the length of the ſtamens; ſtigmas ſimple. *Peric.* Capſules rigid, each of one cell and two valves. *Seeds* ſolitary, bony.

Eſſ. Ch. Calyx inferior, truncated, entire. Corolla none, Germens combined. Capſules of two valves. Seeds ſolitary, bony.

1. F. *alnifolia*. Native of Carolina, and a hardy ſhrub in the Engliſh gardens. There are two varieties, one with blunt leaves figured in John Miller's Icones Plantarum; the other with acute ones, under the name of *F. Gardeni*, Jacq. Ic. Rar. t. 100.—The *leaves* are furniſhed with a few ſhallow ſerratures towards their ends, and are hoary beneath. The *flowers* appear chiefly in May, at the ends of the branches, in the form of white oblong ſpikes or catkins of no great beauty.

FOTHERING, in *Sea Language*, is a peculiar method of endeavouring to ſtop a leak in the bottom of a ſhip while

while ſhe is afloat, either under ſail, or at anchor. It is uſually performed in the following manner: a baſket is filled with aſhes, cinders, and chopped rope-yarns, and looſely covered with a piece of canvas: to this is faſtened a long pole, by which it is plunged repeatedly in the water, as cloſe as poſſible to the place where the leak is conjectured to lie. The oakum or chopped rope-yarns, being thus gradually ſhaken through the twigs, or over the top of the baſket, are frequently ſucked into the hole along with the water, ſo that the leak is choaked, and the entrance of the water prevented. Falconer's Mar. Dict.

FOTHERINGHAY, in *Geography*, a pariſh in the hundred of Willybrook, and county of Northampton, eighty-five miles diſtant from London, connected as it has been with the lives and fates of princes, muſt ever be an intereſting ſpot to the topographer and traveller; as it doubtleſs will be conſpicuous to the lateſt period on the page of hiſtory. Here was formerly a caſtle, probably firſt erected in the time of the Conqueror by Simon St. Liz, ſecond earl of Northampton. It was rebuilt in the reign of Edward III. by Edward Langley, duke of York, who erected the keep in the ſhape of a fetterlock, the emblem or device of the family. By marriage this fortreſs became the property and occaſional reſidence of the Scottiſh kings. In the fourteenth year of king John's reign, David king of Scotland was ſummoned to ſurrender it; and refuſing compliance, the ſheriff was directed by royal mandate to raiſe the poſſe comitatus, and compel him to ſubmiſſion. Edward IV. made this fortreſs his reſidence in the twenty-ſecond year of his reign; when Alexander, king of Scotland, had an audience, and promiſed to do homage and fealty to the crown of England. In the reign of Elizabeth the cuſtody of this caſtle was confided to ſir William Fitzwilliams, at which period it was rendered a ſcene of woe, at the mere idea of which humanity ſhudders, and the mind ſtarts back with horror from the ſanguinary tranſaction. Here Mary Stewart, queen of Scots, was long impriſoned, then tried, condemned, and executed, in the year 1580. Reſpecting the juſtice or injuſtice of the melancholy event much has been written; and while the ingenious Buchanan has uſed all his efforts to detect, and poured forth all his eloquence to emblazon the queen's guilt; a no leſs able writer, Whitaker, has wielded the energies of his genius, and the weapons of his learning, to eſtabliſh her innocence, and demonſtrate her proſecutor's guilt. Camden, who was a cotemporary, and poſſeſſed ample means of arriving at the truth, endeavours to avoid entering into any diſcuſſion upon the point; obſerving, "Let it ever be forgotten if poſſible, but if not, let it ever be wrapped up in ſilence." Fotheringhay, however, notwithſtanding the reſerve of ſome, and the miſrepreſentation of others, notwithſtanding the caſtle is demoliſhed, the walls of the unfortunate princeſs's priſon down, and the hall of judgment no more, will tranſmit the deplorable fact to the lateſt poſterity; and record in its name and ſcite the nefarious tranſaction. The caſtle, from a manuſcript account, and the deſcription given of it by Leland, muſt have been a noble ſtructure, containing numerous apartments, ſecured by ſtrongly fortified walls, with double ditches moated round. But on the acceſſion of James to the crown of England, an order was iſſued for its complete demolition; and nothing at preſent remains except the ſcite, marked out by the moat and part of the agger on which the keep was erected.

At ſome remote period a nunnery had been founded here, on the ſcite of which Edward Langley, duke of York, erected and endowed a ſecular college for a maſter, twelve chaplains, eighteen clerks, and thirteen choriſters; the annual revenues of which, at the diſſolution, amounted, according to Speed, to 489*l.* 15*s.* 9*d.* The conventual is the preſent pariſh church, in which were interred Edward, duke of York, who was ſlain at the battle of Agincourt, in the third year of Henry V.; and Richard Plantagenet, duke of York, who was ſlain at Wakefield, while attempting to obtain acceſſion to the throne on the death of Henry VI. Their ſumptuous monuments having been deſtroyed, two of indifferent workmanſhip were erected at the command of queen Elizabeth: by whoſe munificence alſo a grammar ſchool was erected and endowed.

This village, ſo diſtinguiſhed in hiſtory, was formerly a conſiderable town, and had a weekly market on Wedneſdays, and three annual fairs. At preſent it conſiſts of one ſtreet, containing only 46 houſes and 307 inhabitants.

This was the birth-place of Richard Plantagenet, duke of Glouceſter, afterwards king Richard III.; in whoſe perſon, Fuller obſerves, "Ajax and Ulyſſes met; poſſeſſing eloquence to talk, and valour to fight." He was deformed in body, and by the generality of hiſtorians he has been repreſented as ſtill more deformed in mind. Had he not waded to the throne through the blood of his nephews, Edward V., and Richard, duke of York, whom he is ſaid to have cauſed ſecretly to be murdered in the Tower; he might have appeared to deſerve it; for his ſhort reign was diſtinguiſhed by the enactment of ſeveral excellent laws, and he was not deficient in perſonal courage. Having met Henry, duke of Richmond, who had aſſembled an army againſt him, in Boſworth field, after performing prodigies of valour, the king there loſt both his crown and his life. See Camden's Britannia, and the Beauties of England and Wales.

FOTIPET, a town of Hindooſtan, in Bednore; 5 miles E.N.E. of Bednore.

FOTOQUE, in the *Japaneſe Theology*, the name of an order of deities; the other order being called Camis. From the latter they obtain the bleſſings of this life, and from the former thoſe which relate to a future life.

FOTUS, in *Medicine*, the ſame as fomentation.

FOU, in *Geography*, a town of China, of the ſecond rank, in the province of Chan-ſi; 420 miles S.W. of Peking. N. lat. 26° 5′. E. long. 108° 44′.

FOU-AN, a town of the kingdom of Corea; 35 miles W.N.W. of Cou-fou.

FOUCAULT, Nicholas-Joseph, in *Biography*, was ſon of a ſecretary to the council of ſtate, and was born at Paris in 1643. He was educated for the French bar, at which he afterwards obtained much celebrity, and paſſed through various offices till he became a maſter of requeſts, and chief of the council of madame, ducheſs of Orleans. At the revocation of the edict of Nantes, he exerciſed ſuch prudence in the diſtrict over which he was the intendant, that much of the miſchief was prevented which that arbitrary meaſure was calculated to produce. So grateful are the people, in almoſt all caſes, for favours done them, that in this inſtance a medal was ſtruck in gratitude for the liberality exhibited by Foucault. At the different places in which he ſuſtained any public office, he encouraged the arts and local eſtabliſhments and improvements calculated to benefit the trade of the country. He was the firſt to ſet on foot the conſtruction of new roads, canals, havens, and bridges; and to ſanction, with all his influence, inſtitutions for the promotion of the uſeful arts and ſciences. His own valuable library and cabinet were ever open to thoſe who were able to uſe them. He added much to the ſtock of antiquarian knowledge, by the diſcovery which he made in

1704, of the ancient town of the Viducaſſians, near Caen, of which he laid a particular account before the "Academy of Inſcriptions." He alſo diſcovered a MS. "De Mortibus Perſecutorum," which is generally attributed to Lactantius. Moreri.

FOU-CHAN, in *Geography*, a town of China, of the third rank, in the province of Chang-tong; 25 miles S.E. of Tang-tcheou.

FOUCHENDGE, or FOUSHENGE, a town of Perſia, in the province of Choraſan, taken and plundered in 1380 by Timur Bey, though ſtrongly fortified, 25 miles N. of Herat. N. lat. 34° 50′ E. long. 76° 29′.

FOUCHER, SIMON, in *Biography*, a writer of ſome celebrity, was born at Dijon in the year 1644, where he was educated, afterwards ordained prieſt, and preſented to an honorary canonry. That he might purſue philoſophical ſtudies, to which he was extremely attached, with more freedom and advantage, he removed to Paris, where he acquired the eſteem and friendſhip of many eminent men of the time; but he formed his moſt intimate connection with thoſe who diſtinguiſhed themſelves as advocates for the revival of the academic philoſophy. In the propagation of their ſyſtem he was extremely zealous, and devoted his pen with conſiderable learning in defence of them. He is mentioned by Baillet in terms of high reſpect, who even denominates him "the reſtorer of the academic philoſophy:" and the editors of the "Menagiana" have aſſerted that Menage thought Foucher and Huet were better acquainted with the different ſects of philoſophers than any of their contemporaries. M. Foucher died at Paris in his fifty-third year, and it was ſuppoſed his intenſe application to ſtudy had a great effect in ſhortening his days. He was author of a variety of "Diſſertations," "Criticiſms," "Letters," &c. which form a collection of ſix volumes: alſo of "A Treatiſe on the Wiſdom of the Ancients," publiſhed in one vol. 12mo., intended to ſhew that the principal maxims of their morality are not contrary to the principles enforced by the Chriſtian code: and "A Letter concerning the Morality of Confucius;" and "A Treatiſe on Hygrometers, or Inſtruments for aſcertaining the dryneſs and humidity of the Air." Moreri.

FOUCHS, JOHANN, JOSEPH, a native of Stiria, a province of Germany, in the circle of Auſtria. He appears as an author in 1707, when he publiſhed at Nuremberg a work entitled "Concentum Muſico-inſtrumentale, in 7 partitas diviſum:" and he alſo compoſed an opera, called Eliza, for the birth-day of the empreſs Elizabeth Chriſtina, which was printed at Amſterdam by Le Cane. Soon after this he was appointed firſt maeſtro di cappella to the emperor; but he is beſt known as a learned writer on muſic by his "Gradus ad Parnaſſum ſive manuductio ad compoſitionem muſicæ regularem, methodo novo, ac certa nondum ante tam exacto ordine in lucem edita," written in Latin, and publiſhed in 1725. It is dedicated to the emperor Charles VI., who defrayed the whole expence of the publication. The work is printed in folio, and divided into two books: the firſt is entirely theoretical, and rather a treatiſe on harmonics than practical counterpoint: we have here all the ratios and proportions of muſical intervals, and the arithmetical, harmonical, and geometrical diviſions of the monochord, which may be found in almoſt all elementary books on muſic during the two laſt centuries.

The ſecond book is in dialogue, between a maſter and ſcholar; in which examples are given in notation of the moſt ſimple plain counterpoint, from two to four parts. Then examples of florid counterpoint, and of ligatures or binding notes. After this, the author treats of fugue in 2, 3, and 4 parts. Then of double counterpoint; and laſtly, of variations, modes of the church, various ſubjects of fugue, of taſte, of the eccleſiaſtical ſtyle, a cappella, of the mixed ſtyle, and of recitative. The doctrine in this work is very orthodox, containing no licences, or any thing to which the fathers of the ſcience would object. The leſſons are almoſt all on canto firmo, after the manner of the Neapolitan ſchool.

In 1742 this excellent work was tranſlated into German by Mizlar, and publiſhed at Leipſic, 4to. with notes. The letter-preſs of this edition is well printed; but the plates are engraved in too ſmall a character, and much crowded and confuſed. In 1761 it was tranſlated into Italian, and publiſhed in folio by Manfredi in Carpi. To this verſion is prefixed a recommendatory letter by the celebrated Piccini, in which, with national partiality, and the ſlippancy of a young man, he compliments the author, Fouchs, by ſaying that he was "a German with an Italian underſtanding." Haydn had not then ſurpaſſed all the Italian compoſers of *inſtrumental muſic* in ſcience and invention; nor had the premature genius of Mozart expanded in marvellous maſterpieces of compoſition, both vocal and inſtrumental. Some detached parts of the "Gradus ad Parnaſſum" were publiſhed in England by Welcher about the year 1770, tranſlated by Hoeck; but the entire work has never appeared in our language. The venerable imperial maeſtro di cappella lived to a great age. Quantz tells us (in his own life, written by himſelf) that in the year 1723, he, with Weis, the famous luteniſt, and Grann, the opera compoſer, went to Prague, where moſt of the great muſicians of Europe were aſſembled by order of the emperor Charles VI. to celebrate the feſtival of his being crowned king of Bohemia. Hiſtory does not furniſh a more glorious event for muſic than this ſolemnity, nor a ſimilar inſtance of ſo great a number of eminent profeſſors, of any one art, being collected together.

Upon this occaſion, there was an opera performed in the open air, by a hundred voices, and by two hundred inſtruments. There was not an indifferent ſinger among the principal performers, all were of the firſt claſs. The male parts were filled by Orſini, Domenico, Careſtini, Gaſſati, Coroſini, and Braun, a German *baritono*; the female, by the two ſiſters, Amberville, one of whom was afterwards married to Peroni, a famous player on the violoncello, and the other to Boroſſini, the ſinger.

The opera was called "La Conſtanza e Fortezza," and compoſed by the famous old Fux, imperial chapel-maſter at Vienna. The muſic, which was in the old church ſtyle, was coarſe and dry; but, at the ſame time, grand, and had a better effect, perhaps, with ſo immenſe a band, and in ſuch an immenſe ſpace, than could have been produced by more delicate compoſitions.

FOUCHUN, in *Geography*, a town of China, of the third rank, in the province of Se-tchuen; 30 miles N.W. of Tche-li-leou.

FOUCQUET, NICHOLAS, marquis of Belleiſle, in *Biography*, ſon of Francis Foucquet, viſcount de Vaux, and a counſellor of ſtate, was born in 1615, and brought forwards very early in the departments of law. He was created procureur-general of the parliament of Paris at the early age of thirty-five. By cardinal Mazarin he was made ſuperintendant of the finances, and participated largely in the public plunder, which was carried to an enormous height during the cardinal's adminiſtration. Foucquet is ſaid to have ſpent more than half a million ſterling upon his ſeat of Vaux, where he gave the moſt magnificent entertainments. He was a liberal patron of men of letters, and ac-

quired many friends among them who did not desert him after his disgrace. Foucquet offended the king by attempting to gain the heart of mad. de la Valiere, and he was arrested at Nantes in September 1661. He was committed to prison, and a commission was appointed to try him on various charges, but he defended himself so well, and repelled the attacks of the lawyers so dexterously, that it was full three years before the decision and sentence against him could be pronounced. He was condemned to banishment, which was exchanged for perpetual imprisonment in the citadel of Pignoral. Of the multitudes who had been benefited by his liberality, scarcely any remained faithful to him in his adversity, except some of his literary pensioners. Among these were mademoiselle de Scuderi, La Fontaine, and Pelisson, by the last of whom he was defended in several eloquent memoirs. He bore his change of fortune with firmness, and employed his solitary hours in the composition of various works of piety. He died March 23, 1680, aged 65 years. Moreri.

FOVEA Cordis, the pit of the heart, or rather of the stomach, called also *scrobiculus cordis*.

FOUESNANT, in *Geography*, a town of France, in the department of Finisterre, and chief place of a canton in the district of Quimper; 7 miles S. of Quimper. The town contains 1858, and the canton 5535 inhabitants, on a territory of 155 kiliometres, in 6 communes.

FOU-FONG, a town of China, of the third rank, in the province of Quang-tong; 22 miles E.S.E. of Fong-tsiang.

FOUG, a town of France, in the department of the Meurte; 4 miles W. of Toul.

FOUGATE, Fougasse, or *Fougades*, in the *Art of War*, a little mine, in manner of a well, seldom exceeding ten feet in width, and twelve in depth: dug under some work or post that is likely to be lost; and charged with barrels or sacks of gun-powder, covered with earth. It is frequently placed before the weakest parts of a fortification, as the saliant angles and faces, not defended by a cross-fire, and is set on fire like other mines, with a fauciſſe.

The word is French. M. Huet derives it from *focato*, or *focus, fire*.

FOUGERAI, in *Geography*, a town of France, in the department of the Ille and Vilaine, and chief place of a canton in the district of Rédon; 13 miles E. of Rédon. The town contains 4193, and the canton 4802 inhabitants, on a territory of 120 kiliometres, in 2 communes.

FOUGERES, a town of France, and principal place of a district, in the department of the Ille and Vilaine, containing in its two divisions about 7297 inhabitants, whose chief trade is in leather. The first division contains 3648, and its canton 12,665 inhabitants, on an extent of 165 kiliometres, in 10 communes; and the second division contains 3649, and its canton 14,063 inhabitants, on a territory of 177½ kiliometres, in 9 communes. It is seated on the rivulet Nanson, that falls into the Coesnon, 8 leagues N.E. of Rennes, and 9 S.S.E. of Avranches. It has an abbey and old castle, and was formerly reputed a place of some strength; and is still noted for its four annual fairs.

FOUGHT, in *Biograph.*, a native of Lapland, who, nearly fifty years ago, came to London, and obtained a patent for the sole printing of music, with letter-press types of his own founding, which were very neat, and the first that were used in London. He opened a shop in St. Martin's lane, and published several sets of lessons and sonatas; but by a combination of music-sellers in London, who copied his publications on stamped plates, and undersold him, he was driven out of the kingdom.

Musical types are now very common: but by being long accustomed to stamped notes in pewter plates, the public eye is not pleased with them. The best use to which they are now put is in printing books on the subject of music, where they save the trouble of working small plates of single passages, and examples in notation, into the letter-press.

FOUIN, in *Geography*, a country of Africa, N. of Ardra.

FOU-KEOU, a town of China, of the third rank, in the province of Honan; 30 miles E.N.E. of Hiu.

FOU-KIANG, a town of China, of the third rank, in the province of Quang-tong; 20 miles W.N.W. of Tsin.

FOU-KO, a town of China, of the third rank, in the province of Quang-tong; 65 miles N.N.E. of Kia.

FOUL, in the *Sea Language*, is used when a ship has been long untrimmed, so that grass, weeds, periwinkles, barnacles, or the like, stick or grow to her sides under water. In this state she is said to be foul.

A ship is said to make *foul water*, when, being under sail, she comes into such shoal, or low water, that though her keel doth not touch the ground, yet she comes so near it, that the motion of the water under her raises the mud from the bottom, and so fouls the water.

Foul is also a sea term, importing the running of one ship against another. This happens sometimes by the ungovernable violence of the wind, and sometimes by the carelessness of the people on board; and sometimes happens to ships of the same convoy; sometimes to such as meet accidentally; and sometimes to such as are in port, by means of others coming in. The damages occasioned by running foul, are of the nature of those in which both parties must bear a part; they are usually made half to fall upon the sufferer, and half upon the vessel which did the injury; but in cases where it is evidently the fault of the master of the vessel, he alone is to bear the damage.

Foul *Ground*, of a road, bay, sea-coast, or harbour, signifies that which is rocky, or abounding with shallows, or otherwise dangerous.

Foul *Hause*, denotes that the cables are turned round each other, by the winding or turning about of a ship while she rides at anchor.

Foul *Wind*, expresses that which is unfavourable, or contrary to the course of the ship, in opposition to large or fair.

Foul *Feeding*, in the *Manege*, denotes a voracious appetite, to which some horses are subject, which, though not properly a disease, is the cause of various maladies. It is commonly the effect of some latent distemper, and frequently occasioned by worms irritating the intestines.

Foul feeders will leave their hay to eat their litter, even when it is soaked with their dung and urine, and discover a vitiated as well as a voracious appetite. The best remedy in cases of this kind is to begin with purging, and to dissolve chalk in their water, and afterwards to give them good exercise. The following draught will also serve to blunt their appetites; take a large handful of the roots of marshmallows; cummin seeds, and fenugreek seeds, of each an ounce; liquorice roots sliced, half an ounce; boil them

in three pints of water, till the roots are ſoft and ſlimy; then pour off the decoction, and diſſolve in it an ounce of gum arabic, and add four ounces of linſeed oil. Let the horſe have four handfuls of this mixture every morning faſting, till his appetite abates. Care ſhould alſo be taken to keep the ſtalls as clean as poſſible. Gibſon's Farriery.

Foul *Bay*, in *Geography*, a bay on the N. E. coaſt of the iſland of Barbadoes.—Alſo, a bay on the S. coaſt, near the eaſtern extremity of the iſland of Jamaica. N. lat. 17° 54′. W. long. 75° 56′.—Alſo, a bay on the S. coaſt of the iſland of Java. S. lat. 8° 38′. E. long. 113° 45′.

Foul *Iſland*, a ſmall iſland in the Chineſe ſea, near the coaſt of Cochinchina. N. lat. 11° 37′. E. long. 108° 53′. —Alſo, a ſmall iſland in the bay of Bengal, near the coaſt of Ava. N. lat. 18° 12′. E. long. 94° 11′.

Foul *Iſlands*, a cluſter of ſmall iſlands in the Eaſt Indian ſea, near the N. coaſt of the iſland of Flores. S. lat. 8° 9′. E. long. 121° 22′.

Foul *Point*, a cape on the E. coaſt of Madagaſcar. S. lat. 17° 40′. E. long. 49° 50′. This cape is called by the natives "Voolou-voolou;" and is the place moſt frequented by Europeans. The entrance of the port lies in a northern direction; the breadth of the paſſage is about 50 fathoms, and it is nearly of the ſame depth; it will hold 10 large ſhips, which may be moored all in a line. The riding is ſafe, but between the months of October and June the entrance is ſometimes obſtructed and ſhut up by a bank of quickſand, which diſappears as ſoon as the S. E. winds ſucceed the northern gales and calms. The harbour is formed by coral rocks, which run N.N.E.; and upon theſe are various ſea-plants, moſſes, black corals, madrepores, ſtar-wort, ſea-inſects, and ſhells, which, by the multiplicity of their form, and the brilliancy of their colours, ſerve to decorate the cabinets of the curious. The mouth of the river preſents large beds of delicate and palatable oyſters of peculiar configuration. Ships may be ſupplied with all ſorts of proviſions, which are various and abundant. The villages inhabited by the tribe of "Voolou-voolou" are not very conſiderable; they are fortified with paliſades; moſt of them are erected upon the declivity of hills, and they are delightfully ſhaded by a great number of uſeful trees. The diſtrict of "Voolou-voolou" contains excellent paſture grounds, and a great number of cattle. The river Onglebey, which ſuddenly loſes itſelf in the ſands at the diſtance of 400 fathoms from its mouth, abounds with fiſh and aquatic birds; and canoes row up to a diſtance of more than 20 leagues. It is, however, infeſted with a great number of monſtrous crocodiles, which find a ſecure retreat among the trees that cover its banks.

Foul *Sound*, a ſtrait or paſſage on the weſt of Ireland. It is between Iniſmain and Inniſhere, two of the ſouth iſles of Arran, which lie at the entrance of Galway bay. Beſides a great rock, there is an extenſive ſhoal, which renders this not a good paſſage.

FOULA, one of the Shetland iſlands, which is narrow, high, and rocky, about three miles in length, and affords ſome paſture. Its inhabitants, in number about 150, are almoſt in a ſtate of nature. It has one indifferent landing place. On the W. coaſt are hideous precipices. It is upwards of ſeven leagues W.S.W. from the broadeſt part of the Main-land. Some writers have ſuppoſed this iſland to be the "Ultima Thule" of Tacitus and the ancients. N. lat. 60° 6′. W. long. 2° 17′.

FOULAH, Fouli, or Pholey, a country of Africa, bordering on the river Senegal, and extending about 480 miles from eaſt to weſt; the boundaries from north to ſouth being unknown. This country is populous, and the ſoil fertile, and capable of furniſhing an advantageous commerce, if the inhabitants were induſtrious. Their complexion is generally tawny, though many of them are black; and it is ſuppoſed that they derive their mixed colour, between the true olive and black, from their alliances with the Moors. Although they are remiſs in availing themſelves of the advantages of commerce, they are diligent as farmers and graziers; and raiſe millet, rice, tobacco, cotton, peaſe, roots, and fruits in abundance; nor are they leſs expert in rearing cattle, which is the ſtaple of their traffic with neighbouring countries. Their cattle conſtitute their chief wealth, and accordingly they roam, purſuing a kind of wandering life, from field to field, and from country to country, with large droves of cows, ſheep, goats, and horſes; removing, as the wet and dry ſeaſons require, from the low to the high lands, and continuing no longer in one place than the paſture for their cattle will allow. The inconvenience and labour of this roving life are augmented by the defence they are obliged to provide againſt the depredations of the fierce animals with which the country abounds; as they are moleſted by lions, tigers, and elephants from the land, and crocodiles from the rivers. At night they collect their herds and flocks within a circle of huts and tents in which they live, and where they light fires in order to deter theſe animals from approaching them. The king of the country, called Siratic, though commonly deſtitute of the badges of majeſty, poſſeſſes great authority among his ſubjects, and is as much reſpected by his neighbours as any one on the coaſt. The crown deſcends, not from father to ſon, but from brother to brother, and nephew to nephew. The Foulahs are celebrated by travellers as a people extremely hoſpitable; all perſons, whatever be the country to which they belong, being freely admitted into their huts, and treated with the beſt accommodation they can afford; nor is their humanity leſs worthy of notice than their hoſpitality, for as ſoon as any one of them has the misfortune to fall into ſlavery, all the reſt join their ſtock to redeem him. Their arms conſiſt of bows and arrows, lances, ſwords, daggers, and occaſionally a kind of ſmall fuſee; all which they uſe with a ſingular dexterity, eſpecially in hunting, which is a diverſion to which they are much attached. The game they purſue conſiſts of elephants, lions, tigers, and the fierceſt animals. The teeth of elephants, the ſkins of lions, leopards, and tigers are ſold by them, and the fleſh is dried and ſmoked for uſe and for winter ſtore. The elephants are ſo numerous, that they appear in droves of 200 together, plucking up the ſmall trees, and deſtroying whole fields of corn; ſo that they have recourſe to hunting, not merely as a paſtime, but as the means of ſelf-preſervation.

FOULDAGE. See Faldage.

FOULNESS, in *Geography*, an iſland with a church village, ſeparated by a narrow channel, or arm of the German ocean, from the main land of England, and S.E. part of the county of Eſſex, about 12 miles in circumference, 6 miles E. of Rochford.

Foulness *of Colours*, in *Painting*, is uſed in oppoſition to brightneſs, and denotes a defect of purity. It is ſometimes called *breaking* the colour.

FOULON, or Foullon, John Erard, in *Biography*, was born at Liege, of an ancient and diſtinguiſhed family, in the year 1609: and in 1625 he entered the order of the Jeſuits. He had an excellent underſtanding, and capable of graſping every branch of ſcience. His tutors obſerving that his qualifications were peculiarly adapted to the duties of a preacher, took care to inſtruct him in the requiſites for undertaking the office, and he became celebrated for his

his public ſervices for more than thirty years. He was ſucceſſively appointed rector of the colleges at Huy and Tournay, and died in the latter city in 1668; his death was occaſioned by a peſtilential diſorder which he took by attending on the ſick and the dying. He is known as an author by many theological pieces; by "Commentarii Hiſtorici et Morales ad libros I. and II. Machabæorum, additis liberioribus Excurſibus," in two vols. folio. Alſo by "Hiſtoria Leodienſis, per Epiſcoporum et Principum Seriem digeſta ab origine populi uſque ad Ferdinandi Bavari Tempora," &c. in 3 vols. folio. This work, though not very ably executed, is ſaid to throw much light on the hiſtory of the Low Countries. Moreri.

FOULOU-SOUSOU, in *Geography*, a town of Chineſe Tartary, on the Saghalien; 9 miles N. W. of Telden.

FOULWEATHER, Cape, a cape on the W. coaſt of North America. N. lat. 44° 42'. W. long. 124° 7'.

FOULWIND, Cape, a cape on the N. W. coaſt of Tavai Pœnammoo. S. lat. 41° 55'. W. long. 187° 51'.

FOUMART, a name uſed in ſame parts of England for the pole-cat. See Mustela *Putorius*.

FOU-MING, in *Geography*, a town of China, of the third rank, in the province of Yun-nan; 15 miles N. N. W. of Yun-nan.

FOUNDATION, in *Architecture*, denotes the trenches or excavations dug in the earth by taking away the looſe or ſoft ground, and reducing it to an uniform texture and firm bottom ſo as to reſt an edifice or building with ſecurity, and to prevent fractures after erection.

The ſpecies of ground on which a building may be conſtructed are gravel, ſand, and clay. Gravel is an excellent dry bottom where there are no ſprings. Sand is alſo a very good bottom for houſe-building; but care ſhould be taken to make the foundation ſufficiently deep, and not to make any excavation near it, nor below the level of the bottom, particularly after the erection of the edifice; as ſand partakes in ſome degree of the property of water, a very ſmall force being ſufficient to diſplace the particles, and make them deſcend to the loweſt place; its own gravity is even ſufficient for this purpoſe. Sand is altogether unfit for water-works, without other preparations. Almoſt the whole of the city of Glaſgow is built upon ſand; moſt of the houſes in the principal ſtreet are four ſtories in height, and many of them five. Clay is a firm bed for building, but it is apt to throw damps upwards into the wall. Rock is alſo an excellent bed for the foundation of a building, when it can be eaſily obtained, either by being on the ſurface, or by digging to a depth, ſo as not to occaſion a very conſiderable outlay. It will frequently be a conſiderable ſaving in the conſtruction of the building.

There are many ſituations, however, on which there are occaſions to erect edifices where neither rock nor ground can be found that may be depended on. In order to aſcertain the degree of hardneſs, a lever may be ſo conſtructed as to be moveable round a pin at one end, firmly fixed to an upright ſtandard, and graduated from the centre of motion in the manner of a ſteel-yard, and another ſtandard or upright piece, with a flat bottom fixed at a given diſtance from the fulcrum, with a moveable joint where it connects with the horizontal lever; then a conſtant weight being appended to the arm, and ſlid to and fro until the upright piece with the flat bottom be preſſed into the ground, the diviſion on which the weight falls will ſhew the comparative degree of denſity. The depth to which a foundation ought to be dug might be aſcertained by boring, or by an iron crow.

Palladio ſays that the foundation ought to be one-ſixth of the height of the edifice; but this aſſertion is vague, as a building might reſt as firmly on the ſurface of the ground, as if excavated to any depth, provided that the ſoil is alike ſufficient in both caſes.

If nothing but mud can be obtained, then an artificial bottom muſt be conſtructed of piles and planking. The proportion of the piles may be ſuch that their thickneſs may be one-twelfth part of their length. Their diſtances, and the depth to which they are driven, will depend on the nature of the ſoil; they are ſometimes placed ſo rank as to leave no interſtice; their diſtance ought never to exceed the breadth of the ſtones which are to be laid on them. Tranſverſe pieces of wood, called ſleepers, are faſtened to the tops of the piles, which are levelled for the purpoſe, and then planked over.

In ſome caſes, where the ſoil is not very bad, two or more horizontal rows of timbers are introduced under the ſtone-work, and well faſtened at the angles. This is a good precaution where the maſonry is to be carried up upon narrow piers. Should the ſoil be found firm, except in a few places, which might require to be dug to an immenſe depth, throw arches over the infirm places, obſerving to make the abutments ſufficient.

Forced earth is unfit for a foundation for a conſiderable time.

Foundation is alſo uſed to expreſs the bottom of a wall, conſtructed of greater breadth than the ſuperincumbent parts, in order to reſt the edifice firmly and uniformly, and prevent ſettlements by its greater breadth occaſioning a greater difficulty in penetrating the ground.

The foundation generally conſiſts of one, two, or more courſes, the ſuperior always leſs in breadth than the inferior, and the ſuperior greater than the breadth of the inſiſting wall, with the middle of the courſes, and the middle of the wall ſo regulated as to fall vertically over each other.

The different breadths, from the bottom of the wall to the bed of the building, exceed each other equally in ſucceſſion, and conſequently the projections are alike on both ſides, and to each other. Each courſe which forms the foundation is called a footing, and each projection is called an offset or ſet-off.

The breadth of the foundation, it is evident, muſt always be proportioned to the weight of the ſuperſtructure, and the ſoftneſs of the ground on which it is laid. If the texture of the ground is uniform, and if a wall only is to be erected, the breadth of the foundation will be as the area of the vertical ſection of the wall taken at right angles to the face. Therefore, if the wall is equally thick, the breadth of the foundation will be in the compound ratio of the breadth and height of the inſiſting wall. Thus for example, let a wall 40 feet high and two feet thick have a ſufficient foundation of three feet in thickneſs, what muſt be the breadth of the foundation of a wall 50 feet in height, and $2\frac{1}{4}$ thick upon the like bed of earth; then $2 \times 40 : 2\frac{1}{2} \times 50 :: 3 : 4\frac{11}{16}$ = the anſwer. Again, let us ſuppoſe the bed of the building to vary in texture, and let us ſuppoſe that the former is three degrees of ſoftneſs, and the latter five; in this caſe the breadth of the bottom footing will be in the compound ratio of the height of the wall, its breadth and the degree of ſoftneſs of the ground, the reſt of the data being as in the former example; then $2 \times 40 \times 3 : 2\frac{1}{2} \times 50 \times 5 :: 3 : 7\frac{195}{200}$ = the anſwer. Though a wall is here only ſpoken of, yet the ſame operation will apply to the maſs of the whole fabric, provided that the weight can be aſcertained.

The reader may think the circumſtance rather ſingular, that the foundation of a wall may be thinner than that of the

the ſuperſtructure, but that this may often happen may be eaſily ſhewn, ſince it is the weight only that is in queſtion, and not the magnitude; thus ſuppoſe that a foundation, three feet thick, is ſufficient for a wall two feet thick, and 40 feet high; the very ſame thickneſs of foundation is equally capable of ſupporting a wall four feet thick, and 20 feet high, becauſe the inſiſting weights are alike in both caſes. Therefore the above calculation, leaving out the degree of ſoftneſs of ground, will give the breadth of the foundation of the required wall, equal to the breadth of the inſiſting wall itſelf, when the height of the required wall happens to be equal to the height of the required wall, multiplied by its breadth, and divided by its thickneſs; ſuch would be the caſe in a wall of $26\frac{2}{3}$ feet in height; for $\frac{2 \times 40}{3} = 26\frac{2}{3}$. It is evident, if the height of the wall be leſs than $26\frac{2}{3}$ feet, that the breadth of the foundation will be leſs than that of the wall itſelf. Although this is the caſe with reſpect to the rule, of the principle of which there can be no doubt; yet if the wall itſelf is conſtructed according to reaſon, that is, to proportionate its thickneſs to its height, the ſame thing will not obtain; it is only a prepoſterous thickneſs that occaſions the ſingularity of the circumſtance. The rule only gives the perpendicular preſſure, and ſuppoſe the thickneſs were out of all proportion to the height, it would not be adviſable in any caſe to make the footing leſs than the inſiſting part of the wall, as it would not be ſo able to reſiſt the preſſure of heavy winds.

Other obſervations will be found under the article WALL.

FOUNDATION is alſo uſed figuratively for the eſtabliſhment of a city, empire, or the like.

The Romans reckoned their years from the foundation of Rome, *ab urbe condita*; which we ſometimes expreſs by *ab U. C.* Chronologers make 745 years from the Iſraelites paſſing out of Egypt, to the foundation of Rome.

FOUNDATION alſo denotes a donation, or legacy, either in money, or lands, for the maintenance and ſupport of ſome community, hoſpital, ſchool, lecture, or other work of piety.

Among the order of Auguſtines, there is a foundation for the marrying of poor maids; and another for the furniſhing of truſſes to poor people who have ruptures, or hernias.

The founding and building of a college or hoſpital, is called *foundatio*, *quaſi fundatio*, or *fundamenti locatio*. Co. Lit. 10. The king only can found a college; but there may be a college in reputation founded by others. Dyer, 267. See FOUNDER.

FOUNDAY, in *Metallurgy*, a term uſed by the workers at the iron mines, in many counties of England, for the ſpace of ſix days, in which time they contrive to make a determinate quantity of iron, ſo that they count their work by theſe foundays or weeks.

FOUNDER, he who lays a foundation, or who founds and endows a church, ſchool, religious houſe, or other work of charity and piety.

The founders of churches may preſerve to themſelves the right of patronage, or preſentation to the living. The founder of all corporations, in the ſtricteſt and original ſenſe, is the king alone, for he only can incorporate a ſociety; and in civil incorporations, ſuch as mayor and commonalty, &c. where there are no poſſeſſions or endowments given to the body, there is no other founder but the king; but in eleemoſynary foundations, ſuch as colleges and hoſpitals, where there is an endowment of lands, the law diſtinguiſhes, and makes two ſpecies of foundation; the one *fundatio incipiens*, or the incorporation, in which ſenſe the king is the general founder of all colleges and hoſpitals; the other *fundatio perficiens*, or the dotation of it; in which ſenſe the firſt gift of the revenues is the foundation, and he who gives them is in law the founder; and it is in this laſt ſenſe that we generally call a man the founder of a college or hoſpital (10 Rep. 33.); but if the king and a private perſon join in endowing an eleemoſynary foundation, the king alone ſhall be the founder of it. If it cannot appear by inquiſition, who was the perſon that founded a church or college, it ſhall be intended it was the king; who has power to found a new church, &c. Moor 282.

FOUNDER is alſo an artiſt that melts or caſts metals into various forms, for divers uſes; as guns, bells, ſtatues, bombs, types or printing characters; and other ſmall works, as candleſticks, buckles, &c.

The word in this ſenſe is formed of the French *fondre*, to melt or fuſe. In the Roman law they are called *ſtatuarii*.

From the different productions, or works of the founders, they are differently denominated, as founders of ſmall works; bell-founders; gun-founders; letter-founders; figure caſters, &c. What belongs to each, ſee under FOUNDERY.

FOUNDER, in *Glaſs-making*, is a term appropriated to the green-glaſs houſes, and is the perſon there, who in the ſame office in the white-glaſs-making is called the *conciator*.

FOUNDER's *Furnace*. See FURNACE.

FOUNDERS, *Moulds of*. See MOULDS.

FOUNDERS's *Preſs*. See PRESS.

FOUNDER, in the *Sea Language*. A ſhip is ſaid to founder at ſea, when by an extraordinary leak, or a great ſea breaking in upon her, ſhe is ſo filled with water, that ſhe cannot be freed of it, nor is able to ſwim under it, but ſinks with the weight thereof.

FOUNDERING, in the *Manege*, a diſorder in horſes, whereof there are two kinds, *viz.* in the feet, and in the cheſt.

FOUNDERING *in the Feet*, ariſes from hard riding, ſevere labour, great heats, ſudden colds, &c. which inflame the blood, and, as the farriers term it, melt the greaſe, and make it deſcend downward to the feet, and there ſettle; which cauſes ſuch a numbneſs and pricking in the hoof, that the horſe has no ſenſe of feeling in it, being hardly able to ſtand; or, when he does, ſhaking and trembling as if he had an ague.

A horſe may likewiſe be foundered by wearing ſtraight ſhoes, and by travelling upon hard ground.

It may be known when he is foundered on his fore-feet, and not his hind-feet, by his treading firmly on his hind-feet, and ſparing the other; or his going crouching or crippling on his buttocks.

Sometimes, though rarely, he is foundered in his hind feet, and not his fore; which is known by his ſeeming weak behind; and reſting, as much as poſſible, on the fore-feet.

The general methods of curing this diſtemper are, firſt by paring all the horſe's ſoles ſo thin, that the quick may be ſeen; then bleeding him well at the toes; ſtopping the vein with tallow and reſin; and then having tacked hollow ſhoes on his feet, ſtopping them with bran, tar, and tallow, as boiling hot as may be; which is to be renewed once in two days, for a week together; after which he is to have good exerciſe.

Or, after he is pared thin, and let blood at the toes, his feet are to be ſtopped with cows' dung, kitchen-ſee, tar, and

and foot, boiled together, and poured, boiling hot, into them.

FOUNDERING *in the cheſt or body*, uſually befals a horſe by eating too much provender ſuddenly, when too hot; as alſo by drinking too much upon travelling, when he is hot, and riding him after it; and it denotes a chronic inflammation of thoſe parts in a horſe which are ſituated immediately external to the pleura. Accordingly this diſeaſe, conſiſting in an inflammation of the intercoſtal muſcles, which compoſe the fleſhy parts between the ribs, is called by Gibſon "external pleuriſy." It is known by a ſtiffneſs of the body, ſhoulders, and fore-legs, ſometimes attended with a ſhort dry cough in the beginning, and a ſhrinking when a horſe happens to be handled in thoſe parts.

While recent, it is to be treated as a *pleuriſy* (which ſee), and may be then prevented by bleeding, antimonials, hot-waſhes, and pectoral drinks with nitre. Gibſon alſo adviſes purging, in order to prevent the inflammation extending to the muſcles of the breaſt and ſhoulders, which uſually happens. He objects, however, without ſufficient reaſon, to outward applications; except when any ſwelling appears, with any tendency to break; in which caſe he adviſes to haſten ſuppuration by the common methods. This, it ſhould be recollected, is a chronic diſeaſe; and, like rheumatiſm, admits of bliſtering, ſetons, and the free uſe of external ſtimulants to the cheſt.

Mr. Clark obſerves, that the diſtinction of this diſorder into two kinds is not warranted by any good reaſon; and accordingly he gives the following account of the ſymptoms that occur in the different ſtages of this diſorder, together with the circumſtances that have appeared on diſſecting horſes that have died of it. The founder, he ſays, always proceeds from cold too ſuddenly applied to the body; and whether it be from a current of cold air, or from plunging the body into cold water, when over-heated, the effects are the ſame. The ſymptoms at firſt are theſe; when the horſe begins to cool, he appears very ſtiff and feeble in his fore-quarters, and, when forced to move forwards, he collects his body, as it were, into a heap, and brings his hind feet as far forward under his body as he poſſibly can, in order to remove the preſſure of the weight of his body from the fore-legs and feet: at the ſame time, he ſets his fore-feet to the ground with ſeeming great pain: his fore parts are extremely hot, the legs conſiderably ſwelled, and evidently painful to the animal when touched; a violent fever ſucceeds, which, if not properly treated, terminates in death, or, if the horſe ſurvives the ſhock, in incurable lameneſs. On diſſecting the legs and ſhoulders of thoſe horſes that have died, after an illneſs of a few days, of this diſorder, the blood is generally found extravaſated, the parts having a black appearance, eſpecially between the ſkin and the fleſh. The ſame blackneſs is likewiſe obſerved in the cellular membrane, between the interſtices of the muſcles and tendons; the texture of the veſſels is alſo deſtroyed, and their ſubſtance mortified. Mr. Clark ſtates, that plunging horſes into cold water, when they are over-heated, tends to weaken them; and he alleges this proof of it, communicated by a ſportſman well acquainted with horſes, that, in hunting, when horſes are over-heated, and obliged to go through deep water, eſpecially if they are obliged to ſwim, they ſoon after become faint, jaded, and tired. This is a fact well worthy of notice.

FOUNDERY, or FOUNDRY, the art of melting and caſting all ſorts of metals; particularly braſs, iron, bell-metal, &c. The word is alſo uſed for a place, or work-houſe, furniſhed with furnaces, or forges for this purpoſe. A foundery, in the iron manufacture, is almoſt always connected with the blaſt furnace where the metal is ſmelted from the ore; from this circumſtance we ſo frequently find the ſmelting furnace and its appendages termed a foundery, though in reality the word ſhould be confined to the building for caſting up the metal manufactured at the former; it is there termed the caſting-houſe, (ſee the article BLAST *furnace.*) The caſting-houſe, or foundery, is ſituated on one of the ſides of the furnace, the ſurface of its ground about two feet below the level of the bottom of the hearth of the furnace. The floor of the foundery ſhould be about ten feet deep, with the loamy ſand, as mentioned in the article CASTING, of which the moulds are formed; this is for the convenience of burying large moulds beneath the ſurface, ſo that the metal may be conveyed into them by ſmall channels or ſoughs hollowed out in the ſand. A moſt important circumſtance to be attended to is, that the foundery is well drained of water, as any dampneſs in moulds would produce the fatal exploſions by the ſudden expanſion of the ſteam. When the hot metal is introduced into a wet mould, many ſerious accidents have ariſen from a want of attention to this very neceſſary circumſtance; in ſuch a caſe, the moulds are burſt aſunder, the ground torn up, and the fluid metal thrown in every direction amongſt the workmen, occaſioning as much damage from its projectile force, as from its great heat, to thoſe on whom it falls. Every foundery is furniſhed with a crane, or ſometimes two, placed ſo as to command the whole for the convenience of taking up and removing heavy pieces of caſting from any part of the place. At Buttlerby iron works, Derbyſhire, we noticed an excellent crane for a foundery; the pulley from which the goods are ſuſpended is not fixed to the end of the gib, but ſlided upon it by means of a rack moved by a pinion, which can be turned with eaſe by the workman, ſo as to give the crane any range within its reach; and it can take up weights as well at ſix feet from the centre as at ten, which renders it a moſt uſeful implement in ſuch a ſituation, where the crane is frequently uſed to lower down moulds upon one another in a perpendicular direction, as mentioned in the article CASTING.

The moſt complete founderies are provided with two or more air or reverberating furnaces, (ſee FURNACE,) in which the metal is melted occaſionally, either when the metal contained in the blaſt furnace is not ſufficient, or when the quality of the metal made there is not proper for caſting, owing to its containing too much or too little carbon, and it requires mixing with better or worſe metal to render it fit for the purpoſe.

They have alſo two or three cupolas, or ſmall blaſt furnaces, to melt ſmall quantities of metal, particularly when it is wanted in haſte, as the reverberatories are much longer in filling their charge of metal, though it is in greater quantity; but the latter does not ſo well anſwer the purpoſes of the iron founder, becauſe it would require ſo great a ſtock of flaſks and implements to make moulds to receive a large quantity of metal; for this reaſon they ſeldom employ the reverberatory but for large articles which require the whole charge; ſmaller goods are caſt from the cupolas.

In the foundery of a blaſt furnace, a pit is ſunk at a convenient diſtance from the furnace, and the moulds for pipes, and other ſimilar articles, are placed vertically in it, within reach of the crane: the metal is conveyed by gutters or ſoughs from the furnace, and a ſmall iron trough, filled with ſand, leads the fluid metal into each of the moulds; theſe are a conſiderable improvement on the old method of burying them in the ſand, in the ſaving of labour and time; the flaſks are made of caſt iron for the purpoſe.

It has of late become a practice at our moſt extenſive foun-

founderies, to ſubſtitute ſand for loam caſtings in many caſes where a great number of articles of one kind are to be caſt, ſo that the expence of the flaſks is not an object of importance; where the articles are intricate, the ſand is wetted ſo much to render it ſufficiently adheſive, that it is neceſſary to dry the moulds to avoid the danger of an exploſion: for this purpoſe large ſtoves are uſed, and carriages adapted, on which to convey a great number of moulds into the ſtove at once, and when ſufficiently dry, which generally happens in about half an hour, they are withdrawn, and a new ſet placed on the carriage.

A foundery is generally provided with a boring-mill for forming the internal ſurface of the cylinders caſt for ſteam-engines, &c. (ſee CYLINDER *boring*), and the ſame machinery turns large lathes, for turning heavy mill axes, piſtons, rollers for ſugar-mills, and laminating rollers; the ſame mill gives motion to all theſe, and alſo blows the cupolas, though at a blaſt-furnace theſe are ſupplied by a ſmall pipe from the great blowing-engine for the furnace.

FOUNDERY *of ſmall works, or the manner of caſting in ſand.*—The ſand uſed by the founders, in caſting braſs, &c. is yellowiſh, and pretty ſoft; but, after it has been uſed, it becomes quite black, becauſe of the charcoal-duſt uſed in the moulds. Every time they would uſe this ſand, they work and tew it, ſeveral times over, on a board about a foot ſquare, placed over a kind of trunk, or box, into which it may fall from off the board. This tewing is performed with a roller, or cylinder, about two feet long, and two inches in diameter; and a kind of knife, made of the blade of a ſword: with theſe two inſtruments they alternately roll and cut the ſand; and, at length, turn it down into the box or trough underneath.

Then, taking a wooden board, or table, of a length and breadth proportional to the quantity of things to be caſt; round this they put a frame or ledge; and thus make a ſort of mould. This mould they fill with the ſand before prepared, and moderately moiſtened: which done, they take wooden, or metalline models, or patterns of the things intended to be caſt: apply them on the mould, and preſs them down in the ſand, ſo as to leave their form indented; along the middle of the mould is laid half a little cylinder of braſs, which is to be the maſter-jet, or canal for running the metal; being ſo diſpoſed, as to touch the ledge on one ſide, and only to reach to the laſt pattern on the other: from this are placed ſeveral leſſer jets or branches, reaching to each pattern, whereby the metal is conveyed through the whole frame.

This firſt frame being thus finiſhed, they turn it upſide down, to take out the pattern from the ſand; in order to which, they firſt looſen them a little all round, with a ſmall cutting inſtrument.

After the ſame manner they proceed to work the counterpart, or other half of the mould, with the ſame patterns, in a frame exactly like the former; excepting that it has pins, which, entering holes correſponding thereto in the other, make, when the two are joined together, the two cavities of the pattern fall exactly on each other.

The frame, being thus moulded, is carried to the founder, or melter; who, after enlarging the principal jet, or canal, of the counter-part, with a kind of knife, adding the croſs jets, or canals, to the ſeveral patterns in both, and ſprinkling them over with mill-duſt, ſets them to dry in an oven.

When both parts of the mould are ſufficiently dried, they join them together, by means of the pins; and to prevent their ſtarting, or ſlipping aſide, by the force of the metal, which is to come in flaming hot, through a hole contrived at the maſter-jet, they lock them in a kind of preſs, either with ſcrews; or if the mould be too big for this, with wedges. The moulds, thus put in the preſs, are ranged near the furnace, to be in readineſs to receive the metal as it comes out of the crucible.

While the moulds are thus preparing, the metal is put in fuſion in an earthen crucible, about ten inches high, and four in diameter.

The furnace wherein the fuſion is made is much like the ſmith's forge; having, like that, a chimney, to carry off the ſmoke; a pair of bellows to blow up the fire; and a hearth where the fire is made, and the crucible placed. It is the uſe of this hearth, that chiefly diſtinguiſhes the furnace from the forge.

In the middle thereof is a ſquare cavity, ten or twelve inches wide, which goes to the very bottom: it is divided into two, by an iron grate: the upper partition ſerves to hold the crucible, and the fuel, and the lower to receive the aſhes.

When the fuel, which is to be of dry wood, is pretty well lighted, they put the crucible full of metal in the middle, and cover it with an earthen lid; and, to increaſe the force of the fire, beſides blowing it up with the bellows, they lay a tile over part of the aperture or cavity of the furnace.

The metal firſt put in being brought to a fuſion, they fill the crucible with pieces of braſs beaten in a mortar; to put them in they make uſe of a kind of iron ladle, with a long ſhank at the end thereof, formed into a kind of hollow cylinder, out of which the piece is dropped.

Nothing now remains, but for the founder to take the crucible out of the fire, and carry it in a pair of iron tongs (whoſe feet are bent, the better to embrace the top of the crucible) to the mould; into which he pours the melted metal, through the hole anſwering to the maſter-jet of each mould.

Thus he goes ſucceſſively, from one to another, till his crucible is emptied, or there is not matter enough left for another mould.

Then caſting cold water on the moulds, they take the frames out of the preſſes, and the caſt works out of the ſand: which afterwards they work again, for another caſting. Laſtly, they cut off the jets, or caſts, and ſell or deliver the work to thoſe who beſpoke it, without any farther repairing. See BRASS and CASTING.

FOUNDERY *of ſtatues, great guns, and bells.*—The art of caſting ſtatues in braſs is very ancient; inſomuch that its origin was too remote and obſcure even for the reſearch of Pliny; an author admirably ſkilled at diſcovering the inventors of other arts.

All we can learn for certain is, that it was practiſed, in all its perfection, firſt among the Greeks; and afterwards among the Romans: and that the number of their ſtatues conſecrated to their gods and heroes ſurpaſſed all belief. See STATUE.

The ſingle cities of Athens, Delphos, Rhodes, &c. had each three thouſand ſtatues; and Marcus Scaurus alone, though only ædile, adorned the circus with no leſs than three thouſand ſtatues of braſs, for the time of the Circenſian games. This taſte for ſtatues was finally carried to ſuch a pitch, that it became a proverb, that in Rome the people of braſs were not leſs numerous than the Roman people.

Among us, the caſting of ſtatues was but little known or practiſed before the ſeventeenth century.

As to the *caſting of guns*, it is quite modern; and it were perhaps to be wiſhed, we were as ignorant of it as the ancients.

ancients. All authors agree, that the firſt cannon were caſt in the fourteenth century; though ſome affix the event to the year 1338, and others to 1380. See CANNON and GUNNERY.

The *caſting of bells* is of a middle ſtanding, between the other two. The uſe of bells is certainly very ancient in the weſtern church; and the ſame were likewiſe once uſed in the church of the eaſt. But, at preſent, F. Vanſleb aſſures us, in his ſecond account of Egypt, he had found but one bell in all the eaſtern church, and that in a monaſtery in the Upper Egypt. See BELL.

The matter of theſe large works is rarely any ſimple metal, but commonly a mixture of ſeveral. We ſhall here give the proceſs in the foundery of each.

Method of caſting ſtatues of figures. See BRONZE.

There are three things chiefly required in caſting of ſtatues, buſts, baſſo-relievos, vaſes, and other works of ſculpture: *viz.* the mould, the wax, and ſhell, or coat. The inner mould, or core (thus called from *cœur*, as being in the heart or middle of the ſtatue), is a rude lumpiſh figure, to which is given the attitudes and contours of the ſtatue intended; it is raiſed on an iron grate, ſtrong enough to ſuſtain it; and is ſtrengthened withinſide by ſeveral bars, or ribs of iron.

It may be made at the diſcretion of the workmen; of potters' clay, mixed up with horſe-dung and hair; or of plaſter of Paris, mixed with fine brick-duſt.

The uſe of the core in ſtatues is to ſupport the wax and ſhell, to leſſen the weight, and to ſave metal. In bells it takes up all the inſide, and preſerves the ſpace vacant where the clapper is hung. In great guns it forms the whole chace, from the mouth to the breech: and, in mortars, the chace and chamber. The iron bars and the core are taken out of the braſs figure, through an aperture left in it, which is afterwards ſoldered up: but it is neceſſary to leave ſome of the iron bars of the core that contribute to the ſteadineſs of the projecting parts, within the braſs figure.

The wax is a repreſentation of the intended ſtatue. If it be a piece of ſculpture, the wax muſt be all of the ſculptor's own hand, who uſually faſhions it on the core itſelf; though it may be wrought ſeparately in cavities, moulded, or formed, on a model, and afterwards diſpoſed and arranged on the ribs of iron over the grate, as before, filling the vacant ſpace in the middle with liquid plaſter and brick-duſt; by which means the inner mould, or core, is formed in proportion as the ſculptor carries on the wax.

When the wax (which is to be of the intended thickneſs of the metal) is finiſhed, they fix little waxen tubes perpendicularly to it, from top to bottom; to ſerve, both as jets, for the conveyance of the metal to all parts of the work: and as vent holes, to give paſſage to the air, which would, otherwiſe, occaſion great diſorder, when the hot metal came to encompaſs it. By the weight of the wax uſed herein, is that of the metal adjuſted; ten pounds of this laſt being the proportion to one pound of the former. The work brought thus far, wants nothing but to be covered with its ſhell; which is a kind of coat, or cruſt, laid over the wax: and which, being of a ſoft matter, and even, at firſt, liquid, eaſily takes and preſerves the impreſſion of every part thereof; which it afterwards communicates to the metal, upon its taking the place of the wax, between the ſhell and the core. The matter of this outer mould, or ſhell, is varied according as different layers, or ſtrata are applied. The firſt is a compoſition of clay, and old white crucibles, well ground and ſifted, and mixed up with water, to the conſiſtence of a colour fit for painting: accordingly, they apply it with a pencil, laying it ſeven or eight times over, letting it dry between the intervals. For the ſecond impreſſion, they add horſes' dung and natural earth to the former compoſition. The third impreſſion is only horſes' dung and earth. Laſtly, the ſhell is finiſhed by laying on ſeveral more impreſſions of this laſt matter, made very thick with the hand.

The ſhell, thus finiſhed, is ſecured and ſtrengthened by ſeveral bands, or girts of iron, wound around it at half a foot's diſtance from one another, and faſtened at bottom to the grate under the ſtatue; and at the top to a circle of iron, where they all terminate.

Here it muſt be obſerved, that if the ſtatue be ſo big, that it would not be eaſy to move the moulds, when thus provided, it muſt be wrought on the ſpot where it is to be caſt.

This is performed two ways; in the firſt, a ſquare hole is dug under-ground, much bigger than the mould to be made therein, and its inſides lined with walls of freeſtone, or brick. At the bottom is made a hole, of the ſame materials, with a kind of furnace, having its aperture outwards: in this is a fire to be lighted, to dry the mould; and afterwards, to melt the wax. Over this furnace is placed the grate; and on this the mould, &c. framed as before explained. Laſtly, at one of the edges of the ſquare pit is made another large furnace, to melt the metal, as hereafter mentioned.

In the other way, it is ſufficient to work the mould above-ground: but with the ſame precaution of a furnace, and grate, underneath: when finiſhed, four walls are to be run up round it: and, by the ſide thereof, a maſſive made, for a melting furnace. For the reſt, the method is the ſame in both. The mould being finiſhed, and incloſed between four walls, whether under-ground, or above it, a moderate fire is lighted in the furnace under it, and the hole covered with planks, that the wax may melt gently down, and run out at pipes contrived for the purpoſe, at the foot of the mould; which are afterwards very exactly cloſed with earth, as ſoon as all the wax is carried off.

This done, the hole is filled up with bricks thrown in at random, and the fire in the furnace is augmented till ſuch time as both the bricks and the mould become red-hot; which ordinarily happens in twenty-four hours. Then, the fire being extinguiſhed, and every thing cold again, they take out the bricks, and fill up their place with earth, moiſtened, and a little beaten, to the top of the mould, in order to make it the more firm and ſteady.

Things being in this condition, there remains nothing but to melt the metal, and run it into the mould; this is the office of the furnace above, which is made in manner of an oven, with three apertures; one to put in the wood; another for a vent; and a third to run the metal out at. From this laſt aperture, which is kept very cloſe whilſt the metal is in fuſion, a little tube or canal is laid, whereby the melted metal is conveyed into a large earthen baſon over the mould; into the bottom of which all the big branches of the jets, or caſts, which are to carry the metal into all the parts of the mould, are inſerted.

It muſt be added, that theſe jets are all terminated, or ſtopped with a kind of plugs, which are kept cloſe, that upon opening the furnace the braſs, which guſhes out like a torrent of fire, may not enter any of them till the baſon be full enough of matter to run into them all at once; upon which occaſion they pull out the plugs, which are long iron rods, with a head at one end, capable of filling the whole diameter of each tube. The hole of the furnace

is opened with a long piece of iron, fitted at the end of a pole; and the mould is then filled in an inſtant. The work is now finiſhed, at leaſt ſo much as belongs to the caſting, the reſt being the ſculptor's or carver's buſineſs; who, taking the figure out of the mould and earth with which it is encompaſſed, ſaws off the jets, wherewith it appears covered over; and repairs it, with inſtruments proper to his art; as chiſſels, gravers, punchreons, &c.

The manner of caſting bells.—What has been hitherto ſhewn of the caſting of ſtatues, holds, in proportion, of the caſting of bells; that which is particular in theſe latter is as follows: firſt, then, the metal is different; there being no tin in the metal of ſtatues, but no leſs than a fifth part of tin in that of bells. Secondly, the dimenſions of the core, and the wax of bells, eſpecially if it be a ring of ſeveral bells that is to be caſt, are not left to chance, or the caprice of the workman; but muſt be meaſured, on a kind of ſcale, or diapaſon; which gives the height, aperture, and thickneſs, neceſſary for the ſeveral tones required.

It need not be added, that it is on the wax that the ſeveral mouldings and other ornaments, and inſcriptions, to be repreſented in relievo, on the outſide of the bell, are formed. The clapper, or tongue, is not properly a part of the bell, but is furniſhed from other hands. In Europe, it is uſually of iron, with a large knob at the extreme; and is ſuſpended in the middle of the bell. In China, it is only a huge wooden mallet, ſtruck by force of arm againſt the bell; whence they can have but little of that conſonancy, ſo much admired in ſome of our rings of bells. The Chineſe have an extraordinary way of increaſing the ſound of their bells; *viz.* by leaving a hole under the cannon; which our bell-founders would reckon a defect.

The proportions of our bells differ very much from thoſe of the Chineſe. In our's, the modern proportions are, to make the diameter fifteen times the thickneſs of the brim, and the height twelve times. The parts of a bell are, 1. The ſounding bow, terminated by an inferior circle, which grows thinner and thinner. 2. The brim or that part of a bell whereon the clapper ſtrikes, and which is thicker than the reſt. 3. The outward ſinking of the middle of the bell, or the point under which it grows wider to the brim. 4. The waiſt or furniture, and the part that grows wider and thicker quite to the brim. 5. The upper vaſe, or that part which is above the waiſt. 6. The pallet which ſupports the ſtaple of the clapper within. 7. The bent and hollowed branches of metal uniting with the cannons, to receive the iron keys, whereby the bell is hung up to the beam which is its ſupport and counterpoiſe, when rung out. The buſineſs of bell-foundery is reducible to three particulars. 1. The proportion of a bell. 2. The forming of the mould. And, 3. The melting of the metal. There are two kinds of proportions, *viz.* the ſimple and the relative; the former are thoſe proportions only that are between the ſeveral parts of a bell to render it ſonorous; the relative proportions eſtabliſh a requiſite harmony between ſeveral bells. The method of forming the profile of a bell, previouſly to its being caſt, in which the proportion of the ſeveral parts may be ſeen, is as follows: the thickneſs of the brim, C 1 (ſee *Plate* XV. *Miſcellan. fig.* 1.) is the foundation of every other meaſure, and is divided into three equal parts. Firſt, draw the line H D, which repreſents the diameter of the bell; biſect it in F and erect the perpendicular F f; let D F and H F be alſo biſected in E and G, and two other perpendiculars, E e, G a; be erected at E and G: G E will be the diameter of the top or upper vaſe, *i. e.* the diameter of the top will be half that of the bell; and it will, therefore, be the diameter of the bell which will ſound an octave to the other. Divide the diameter of the bell or the line H D into fifteen equal parts, and one of theſe will give C 1 the thickneſs of the brim; divide again each of theſe fifteen equal parts into three other equal parts, and then form a ſcale. From this ſcale take twelve of the larger diviſions, or $\frac{2}{15}$ of the whole ſcale in the compaſs, and ſetting one leg in D deſcribe an arc to cut the line E e in N, draw N D, and divide this line into twelve equal parts; at the point 1 erect the perpendicular 1 C = 10, and C 1 will be the thickneſs of the brim = $\frac{1}{15}$ of the diameter: draw the line C D; biſect D N and at the point of biſection 6 erect the perpendicular 6 K = $1\frac{1}{2}$ of the larger diviſions on the ſcale. With an opening of the compaſs equal to twice the length of the ſcale or thirty brims, ſetting one leg in N, deſcribe an arc of a circle, and with the ſame leg in K and the ſame opening deſcribe another arc to interſect the former: on this point of interſection, as a centre, and with a radius equal to thirty brims, deſcribe the arc N K; in 6 K produced take K B = $\frac{1}{3}$ of the larger meaſure of the ſcale or $\frac{1}{3}$ of the brim, and on the ſame centre with the radius $30\frac{1}{3}$ brims deſcribe an arc A B parallel to N K. For the arc B C, take twelve diviſions of the ſcale or twelve brims in the compaſs, find a centre, and from that centre, with this opening, deſcribe the arc B C, in the ſame manner as N K or A B was deſcribed. There are various ways of deſcribing the arc K p; ſome deſcribe it on a centre at the diſtance of nine brims from the points p and K; others, as it is done in the figure, on a centre at the diſtance only of ſeven brims from thoſe points. But it is neceſſary firſt to find the point p, and to determine the rounding of the bell p 1. For this purpoſe, on the point C as a centre and with the radius C 1 deſcribe the arc 1 p n; biſect the part 1, 2 of the line D n, and erecting the perpendicular p m, this perpendicular will cut the arc 1 p n in m, which terminates the rounding 1 p. Some founders make the bendings K a third of a brim lower than the middle of the line D N; others make the part C 1 D more acute, and inſtead of making C 1 perpendicular to D N at 1, draw it $\frac{1}{6}$th of a brim higher, making it ſtill equal to one brim; ſo that the line 1 D is longer than the brim C 1. In order to trace out the top-part N *a*, take in the compaſs eight diviſions of the ſcale or eight brims, and on the points N and D, as centres, deſcribe arcs to interſect each other in 8; on this point 8, with a radius of eight brims, deſcribe the arc N b; this arc will be the exterior curve of the top or crown; on the ſame point 8, as a centre and with a radius equal to $7\frac{2}{3}$ brims, deſcribe the arc A e, and this will be the interior curve of the crown, and its whole thickneſs will be one-third of the brim. As the point 8 does not fall in the axis of the bell, a centre M may be found in the axis by deſcribing, with the interval of eight brims on the centres D and H, arcs which will interſect in M; and this point may be made the centre of the inner and outer curves of the crown, as before. The thickneſs of the cap which ſtrengthens the crown at Q is about one-third of the thickneſs of the brim; and the hollow branches or ears about one-ſixth of the diameter of the bell. The height of the bell is in proportion to its diameter as twelve to fifteen, or in the proportion of the fundamental ſound to its third major; whence it follows that the ſound of a bell is principally compoſed of the ſound of its extremity or brim, as a fundamental, of the ſound of the crown which is an octave to it, and of that of the height which is a third. Encyclopedie, Art. Cloche. See Bell.

The particulars neceſſary for making the mould of a bell are, 1. The earth: the moſt coheſive is the beſt; it muſt be well ground and ſifted, to prevent any chinks. 2. Brick-ſtone; which muſt be uſed for the mine, mould, or core,

and for the furnace. 3. Horſe dung, hair, and hemp, mixed with the earth, to render the cement more binding. 4. The wax for inſcriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a ſlight layer of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould.

For making the mould, they have a ſcaffold conſiſting of four boards, ranged upon treſſels. Upon this they carry the earth, groſsly diluted, to mix it with horſe-dung, beating the whole with a large ſpatula.

The compaſſes of conſtruction are the chief inſtrument for making the mould, which conſiſt of two different legs, joined by a third piece. And laſt of all, the founders' ſhelves, on which are the engravings of the letters, cartridges, coats of arms, &c.

They firſt dig a hole, of a ſufficient depth to contain the mould of the bell, together with the caſe, or cannon, under ground; and about ſix inches lower than the terre-plein, where the work is performed. The hole muſt be wide enough for a free paſſage between the mould and walls of the hole; or between one mould and another, when ſeveral bells are to be caſt. At the centre of the hole is a ſtake erected, that is ſtrongly faſtened in the ground. This ſupports an iron-peg, on which the pivot of the ſecond branch of the compaſſes turns. The ſtake is encompaſſed with a ſolid brick-work, perfectly round, about half a foot high, and of the propoſed bell's diameter. This they call a mill-ſtone. The parts of the mould are the core, the model of the bell, and the ſhell. When the outer ſurface of the core is formed, they begin to raiſe the core, which is made of bricks that are laid in courſes of equal height upon a layer of plain earth. At the laying of each brick, they bring near it the branch of the compaſſes, on which the curve of the core is ſhaped, ſo as that there may remain between it and the curve the diſtance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an opening for the coals to bake the core. This work is covered with a layer of cement made of earth and horſe-dung, on which they move the compaſſes of conſtruction, to make it of an even ſmoothneſs every where.

The firſt layer being finiſhed, they put the fire to the core, by filling it half with coals, through an opening that is kept ſhut, during the baking, with a cake of earth, that has been ſeparately baked. The firſt fire conſumes the ſtake, and the fire is left in the core half, or, ſometimes, a whole day: the firſt layer being thoroughly dry, they cover it with a ſecond, third, and fourth; each being ſmoothed by the board of the compaſſes, and thoroughly dried before they proceed to another.

The core being completed, they take the compaſſes to pieces, with intent to cut off the thickneſs of the model, and the compaſſes are immediately put in their place, to begin a ſecond piece of the mould. It conſiſts of a mixture of earth and hair, applied with the hand on the core, in ſeveral cakes that cloſe together. This work is finiſhed by ſeveral layers of a thinner cement of the ſame matter, ſmoothed by the compaſſes, and thoroughly dried, before another is laid on. The laſt layer of the model is a mixture of wax and greaſe ſpread over the whole. After which are applied the inſcriptions, coats of arms, &c. beſmeared with a pencil dipped in a veſſel of wax on a chaffing-diſh: this is done for every letter. Before the ſhell is begun, the compaſſes are taken to pieces, to cut off all the wood that fills the place of the thickneſs to be given to the ſhell.

The firſt layer is the ſame earth with the reſt, ſifted very fine; whilſt it is tempering in water, it is mixed with cow's hair, to make it cohere. The whole being a thin cullis, is gently poured on the model, that ſinks exactly all the ſinuoſities of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they cover it with a ſecond of the ſame matter, but ſomething thicker: when this ſecond layer becomes of ſome conſiſtence, they apply the compaſſes again, and light a fire in the core, ſo as to melt off the wax of the inſcriptions, &c.

After this, they go on with other layers of the ſhell, by means of the compaſſes. Here they add to the cow's hair a quantity of hemp, ſpread upon the layers, and afterwards ſmoothed by the board of the compaſſes. The thickneſs of the ſhell comes to four or five inches lower than the mill-ſtone before obſerved, and ſurrounds it quite cloſe, which prevents the extravaſation of the metal. The wax ſhould be taken out before the melting of the metal.

The ear of the bell requires a ſeparate work, which is done during the drying of the ſeveral incruſtations of the cement. It has ſeven rings, the ſeventh is called the bridge, and unites the others, being a perpendicular ſupport to ſtrengthen the curves. It has an aperture at the top, to admit a large iron peg, bent at the bottom; and this is introduced into two holes in the beam, faſtened with two ſtrong iron keys. There are models made of the rings, with maſſes of beaten earth, that are dried in the fire, in order to have the hollow of them. Theſe rings are gently preſſed upon a layer of earth and cow's hair, one-half of its depth; and then taken out without breaking the mould. This operation is repeated twelve times for twelve half-moulds, that two and two united may make the hollows of the ſix rings: the ſame they do for the hollow of the bridge, and bake them all, to unite them together.

Upon the open place left for the coals to be put in, are placed the rings that conſtitute the ear. They firſt put into this open place the iron ring to ſupport the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickneſs of the core. This cake, after baking, is clapped upon the opening, and ſoldered with a thin mortar ſpread over it, which binds the cover cloſe to the core.

The hollow of the model is filled with an earth, ſufficiently moiſt, to fix on the place, which is ſtrewed, at ſeveral times, upon the cover of the core; and they beat it gently with a peſtle to a proper height; and a workman ſmooths the earth at top with a wooden trowel dipped in water.

Upon this cover, to be taken off afterwards, they aſſemble the hollows of the rings. When every thing is in its proper place, they ſtrengthen the outſide of the hollows with mortar, in order to bind them with the bridge, and keep them ſteady at the bottom, by means of a cake of the ſame mortar which fills up the whole aperture of the ſhell. This they let dry, that it may be removed without breaking. To make room for the metal they pull off the hollows of the rings, through which the metal is to paſs, before it enters into the vacuity of the mould. The ſhell being unloaded of its ear, they range under the mill-ſtone five or ſix pieces of wood, about two feet long, and thick enough to reach almoſt the lower part of the ſhell; between theſe and the mould they drive in wooden wedges with a mallet, to ſhake the ſhell of the model whereon it reſts, ſo as to be pulled up, and got out of the pit.

When this and the wax are removed, they break the model and layer of earth, through which the metal muſt run, from the hollow of the rings, between the bell and the core.

They ſmoke the inſide of the ſhell, by burning ſtraw under it, that helps to ſmooth the ſurface of the bell. Then they put the ſhell in the place, ſo as to leave the ſame interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a maſs of baked cement. After which they put on this maſs of the cap, the rings, and vents, over the ſhell, and ſolder it with thin cement, which is dried gradually by covering it with burning coals. Then they fill up the pit with earth, beating it ſtrongly all the time, round the mould.

The furnace has a place for the fire, and another for the metal. The fire-place has a large chimney, with a ſpacious aſh-hole: the furnace which contains the metal is vaulted, whoſe bottom is made of earth, rammed down; the reſt is built with brick. It has four apertures; the firſt, through which the flame reverberates; the ſecond is cloſed with a ſtopple, that is opened for the metal to run; the others are to ſeparate the droſs, or ſcoriæ, of the metal by wooden rakes; through theſe laſt apertures paſſes the thick ſmoke. The ground of the furnace is built ſloping, for the metal to run down. See Dict. Commerc. Eng. edit. art. FOUNDERY.

FOUNDERY. *Manner of caſting great guns, or pieces of artillery.*—The caſting of cannons, mortars, and other pieces of artillery, is performed much like that of ſtatues and bells; eſpecially as to what regards the wax, ſhell, and furnaces.

All pieces of artillery are now caſt ſolid, and bored afterwards, by means of a machine invented at Straſburgh, (ſee *Boring of* CANNON,) and much improved by Mr. Verbruggen, head founder at Woolwich. The gun to be bored was at firſt placed in a perpendicular poſition; but the machines uſed for this purpoſe have lately been made to bore horizontally, and much more exactly than thoſe that bore in a vertical ſituation. Whilſt the inſide is bored, the outſide is turned and poliſhed at the ſame time.

As to the metal, it is ſomewhat different from both; as having a mixture of tin, which is not in that of ſtatues; and only having half the quantity of tin that is in bells, *i. e.* at the rate of ten pound of tin to an hundred of copper. The reſpective quantities of different metals that ſhould enter into the compoſition for braſs cannon is not abſolutely decided; the moſt common proportions of the ingredients are the following: *viz.* to 240lb. of metal fit for caſting, they put 68lb. of copper, 25lb. of braſs, and 12lb. of tin. To 4200lb. of metal fit for caſting, the Germans put 3687$\frac{3}{4}\frac{3}{1}$lb. of copper, 204$\frac{1}{4}\frac{3}{1}$lb. of braſs, and 307$\frac{3}{4}\frac{0}{1}$lb. of tin. Others, again, uſe 100lb. of copper, 6lb. of braſs, and 9lb. of tin; and laſtly, others make uſe of 100lb. of copper, 10lb. of braſs, and 15lb. of tin. See CANNON.

A cannon is always ſhaped a little conical, being thickeſt of metal at the breech, where the greateſt effort of the gunpowder is made, and diminiſhing thence to the muzzle; ſo that if the mouth be two inches thick of metal, the breech is ſix. See CANNON.

Its length is meaſured in calibers, *i. e.* in diameters of the muzzle. Six inches at the muzzle require twenty calibers, or ten feet in length; there is always about the ſixth of an inch allowed play for the ball. For the parts, and their reſpective proportions of different ſorts of guns, ſee CANNON and GUN. The method of caſting iron cannon differs very little from that of braſs.

FOUNDERY, *Letter, or the method of caſting printing Letters.*—The invention of printing letters we ſhall ſpeak of under PRINTING and LETTER.

Their difference, kind, &c. have already been explained under the articles CHARACTER, &c.

In the buſineſs of cutting, caſting, &c. letters for printing, the letter-cutter muſt be provided with a vice, hand-vice, hammers and files of all ſorts for watch-makers' uſe; as alſo gravers and ſculpters of all ſorts, and an oil-ſtone, &c. ſuitable and ſizeable to the ſeveral letters to be cut: a flat gauge made of box to hold a rod of ſteel, or the body of a mould, &c. exactly perpendicular to the flat of the uſing-file: a ſliding gauge, whoſe uſe is to meaſure and ſet off diſtances between the ſhoulder and the tooth, and to mark it off from the end, or from the edge of the work; a face-gauge, which is a ſquare notch cut with a file into the edge of a thin plate of ſteel, iron, or braſs, of the thickneſs of a piece of common tin, whoſe uſe is to proportion the face of each ſort of letter, *viz.* long letters, aſcending letters, and ſhort letters. So there muſt be three gauges, and the gauge for the long letters is the length of the whole body ſuppoſed to be divided into forty-two equal parts. The gauge for the aſcending letters, Roman and Italic, are $\frac{5}{7}$, or 30 parts of 42, and 33 parts for the Engliſh face. The gauge for the ſhort letters is $\frac{3}{7}$ or 18 parts of 42 of the whole body for the Roman and Italic, and 22 parts for the Engliſh face.

The Italic and other ſtanding gauges are to meaſure the ſcope of the Italic ſtems, by applying the top and bottom of the gauge to the top and bottom lines of the letters, and the other ſide of the gauge to the ſtem; for when the letter complies with theſe three ſides of the gauge, that letter has its true ſhape.

The next care of the letter-cutter is to prepare good ſteel punches, well-tempered, and quite free from all veins of iron; on the face of which he draws or marks the exact ſhape of the letter, with pen and ink, if the letter be large; or with a ſmooth blunted point of a needle, if it be ſmall; and then with ſizeable and proper ſhaped and pointed gravers and ſculpters, digs or ſculps out the ſteel between the ſtrokes or marks he made on the face of the punch, and leaves the marks ſtanding on the face. Having well ſhaped the inſide ſtrokes of his letter, he deepens the hollows with the ſame tools: for if a letter be not deep in proportion to its width, it will, when uſed at preſs, print black, and be good for nothing. This work is generally regulated by the depth of the counter-punch. Then he works the outſide with proper files till it be fit for the matrice.

But before we proceed to the ſinking and juſtifying of the matrices, we muſt provide a mould to juſtify them by, of which you have a draught in *Plate* XV. *Miſcellany, figs.* 2, 3.

Every mould is compoſed of an upper and an under part. The under part is delineated in *fig.* 2. The upper part is marked *fig.* 3, and is in all reſpects made like the under part, excepting the ſtool behind, and the bow, or ſpring, alſo behind; and excepting a ſmall roundiſh wire between the body and carriage, near the break where the under part hath a ſmall rounding groove made in the body. This wire, or rather half-wire, in the upper part, makes the nick in the ſhank of the letter, when part of it is received into the groove in the under part. Theſe two parts are ſo exactly fitted and gauged into one another (*viz.* the male gauge, marked c in *fig.* 3. into the female marked g in *fig.* 2.) that when the upper part of the mould is properly placed on, and in the under part of the mould, both together, make the entire mould, and may be ſlid backwards for uſe ſo far, till the edge of either of the bodies on the middle of either carriage comes juſt to the edge of the female gauges, cut in each carriage: and they may be ſlid for-

wards

wards ſo far, till the bodies on either carriage touch each other; and the ſliding of theſe two parts of the mould backwards makes the ſhank of the letter thicker, becauſe the bodies in each part ſtand wider aſunder, and the ſliding them forwards makes the ſhank of the letter thinner, becauſe the bodies on each part of the mould ſtand cloſer together.

The parts of the mould are as follow: *viz.*

a The carriage.
b The body.
c The male gauge.
d e The mouth-piece.
f i The regiſter.
g The female gauge.
h The hag.
a a a a The bottom plate.
b b b The wood, on which the bottom plate lies.
c c c The mouth.
d d The throat.
e d d The pallet.
f The nick.
g g The ſtool.
h h The ſpring or bow.

Then the mould muſt be juſtified: and firſt the founder juſtifies the body, by caſting about twenty proofs or ſamples of letters, which are ſet in a compoſing ſtick, with all their nicks towards the right hand; and then by comparing theſe with the pattern letters, ſet up in the ſame manner, he finds the exact meaſure of the body to be caſt. He alſo tries if the two ſides of the body are parallel, or that the body be no bigger at the head than at the foot; by taking half the number of his proofs, and turning them with their heads to the feet of the other half; and if then the heads and the feet be found exactly even upon each other, and neither to drive out nor get in, the two ſides may be pronounced parallel. He farther tries whether the two ſides of the thickneſs of the letter be parallel by firſt ſetting his proofs in the compoſing ſtick with their nicks upwards; and then turning one-half with their heads to the feet of the other half: and if the heads and feet lie exactly upon each other, and neither drive out nor get in, the two ſides of the thickneſs are parallel.

The mould thus juſtified: the next buſineſs is to prepare the matrices. A matrice is a piece of braſs or copper of about an inch and a half long, and of a thickneſs in proportion to the ſize of the letter it is to contain. In this metal is ſunk the face of the letter intended to be caſt, by ſtriking the letter punch about the depth of an n. After this the ſides and face of the matrice muſt be juſtified and cleared, with files, of all bunchings made by ſinking the punch.

Every thing thus prepared, it is brought to the furnace, which is built of brick upright, with four ſquare ſides, and a ſtone on the top, in which ſtone is a wide round hole for the pan to ſtand in. A foundery of any conſequence has ſeveral of theſe furnaces in it.

As to the metal of which the types are to be caſt, this, in extenſive founderies, is always prepared in large quantities; but caſt into ſmall bars of about twenty pounds weight to be delivered out to the workmen as occaſion requires. In the letter foundery which has been long carried on with reputation, under the direction of Dr. Alexander Wilſon, and ſons, at Glaſgow, we are informed, that a ſtock of metal is made up at two different times of the year, ſufficient to ſerve the caſters at the furnace for ſix months each time. For this purpoſe a large furnace is built under a ſhade, furniſhed with a wheel vent, in order the more equally to heat the ſides of a ſtrong pot of caſt iron, which holds, when full, fifteen hundred weight of the metal. The fire being kindled below, the bars of lead are let ſoftly down into the pot, and their fuſion promoted by throwing in ſome pitch and tallow, which ſoon inflame. An outer chimney, which is built ſo as to project about a foot over the fartheſt lip of the pot, catches hold of the flame by a ſtrong draught, and makes it act very powerfully in melting lead; whilſt it ſerves at the ſame time to convey away all the fumes, &c. from the workmen, to whom this laborious part of the buſineſs is committed. When the lead is thoroughly melted, a due proportion of the regulus of antimony and other ingredients are put in, and ſome more tallow is inflamed, to make the whole incorporate ſooner. The workmen now having mixed the contents of the pot very thoroughly, by ſtirring long with a large iron ladle, next proceed to draw the metal off into the ſmall troughs of caſt iron which are ranged, to the number of fourſcore, upon a level platform, faced with ſtone, built towards the right hand. In the courſe of a day fifteen hundred weight of metal can be eaſily prepared in this manner; and the operation is continued for as many days as are neceſſary to prepare a ſtock of metal, of all the various degrees of hardneſs. After this the whole is diſpoſed into preſſes, according to its quality, to be delivered out occaſionally to the workmen.

The founder muſt be now provided with a ladle, which differs nothing from other iron ladles, but in its ſize. And he is provided always with ladles of ſeveral ſizes, which he uſes according to the ſize of the letter he is to caſt. Before the caſter begins to caſt, he muſt kindle his fire in the furnace to melt the metal in the pan. Therefore he takes the pan out of the hole in the ſtone, and there lays in coals and kindles them; and, when they are well kindled, he ſets the pan in again and puts in metal into it to melt; if it be a ſmall bodied letter he caſts, or a thin letter of great bodies, his metal muſt be very hot; nay ſometimes red-hot, to make the letter come. Then having choſen a ladle that will hold about ſo much as the letter and break is, he lays it at the ſtoking hole, where the flame burſts out, to heat. Then he ties a thin leather, cut with its narrow end againſt the face to the leather groove of the matrice, by whipping a brown thread twice about the leather-groove, and faſtening the thread with a knot. Then he puts both halves of the mould together, and puts the matrice into the matrice-cheek, and places the foot of the matrice on the ſtool of the mould, and the broad end of the leather upon the wood of the upper half of the mould, but not tight up, leſt it might hinder the foot of the matrice from ſinking cloſe down upon the ſtool in a train of work. Then laying a little roſin on the upper-wood of the mould, and having his caſting-ladle hot, he with the bolling ſide of it melts the roſin: and, when it is yet melted, preſſes the broad end of the leather hard down on the wood, and ſo faſtens it to the wood: all this is the preparation.

Now he comes to caſting. Wherefore placing the under half of the mould in his left hand with the hook or hag forward, he clutches the ends of its wood between the lower part of the ball of his thumb and his three hind fingers; then he lays the upper half of the mould upon the under half, ſo that the male gauges may fall into the female gauges, and at the ſame time the foot of the matrice places itſelf upon the ſtool; and, claſping his left hand

hand thumb ſtrong over the upper half of the mould he nimbly catches hold of the bow or ſpring with his right hand fingers at the top of it, and his thumb under it, and places the point of it againſt the middle of the notch in the backſide of the matrice, preſſing it as well forwards towards the mould, as downwards, by the ſhoulder, of the notch cloſe upon the ſtool, while at the ſame time with his hinder fingers, as aforeſaid, he draws the under half of the mould towards the ball of his thumb, and thruſts by the ball of his thumb the upper part towards his fingers, that both the regiſters of the mould may preſs againſt both ſides of the matrice, and his thumb and fingers preſs both halves of the mould cloſe together.

Then he takes the handle of his ladle in his right hand, and with the boll of it gives a ſtroke, two or three, outwards upon the ſurface of the melted metal, to ſcum or clear it from the film or duſt that may ſwim upon it; then takes up the ladle full of metal, and having his mould, as aforeſaid, in his left hand, he a little twiſts the left ſide of his body from the furnace, and brings the geat of his ladle (full of metal) to the mouth of the mould, and twiſts the upper part of his right hand towards him to turn the metal into it, while at the ſame moment of time he jilts the mould in his left hand forwards, to receive the metal with a ſtrong ſhake (as it is called); not only into the bodies of the mould, but while the metal is yet hot running, ſwiftly and ſtrongly, into the very face of the matrice, to receive its perfect form there, as well as in the ſhank.

Then he takes the upper half of the mould off the under half, by placing his right hand thumb on the end of the wood next his left hand thumb, and his two middle-fingers at the other end of the wood; and finding the letter and break lie in the under half of the mould, (as moſt commonly by reaſon of its weight it does,) he throws or toſſes the letter, break and all, upon a ſheet of waſte paper laid for that purpoſe on the bench, juſt a little beyond his left hand, and is then ready to caſt another letter as before; and alſo, the whole number that is to be caſt with that matrice.

A workman will ordinarily caſt about three thouſand of theſe letters in a day.

When the caſters at the furnace have got a ſufficient number of types upon the tables, a ſet of boys come, and nimbly break away the jets from them: the jets are thrown into the pots, and the types are carried away in parcels to other boys, who paſs them ſwiftly under their fingers, defended by leather, upon ſmooth flat ſtones, in order to poliſh their broad-ſides. This is a very dextrous operation, and is a remarkable inſtance of what may be effected by the power of habit and long practice; for theſe boys, in turning up the other ſide of the type, do it ſo quickly by a mere touch of the fingers of the left hand, as not to require the leaſt perceptible intermiſſion in the motion of the right hand upon the ſtone. The types, thus finely ſmoothed and flattened on the broad-ſides, are next carried to another ſet of boys, who ſit at a ſquare table, two on each ſide, and there are ranged up on long rulers, or ſticks, fitted with a ſmall projection, to hinder them from ſliding off backwards. When theſe ſticks are ſo filled, they are placed, two and two, upon a ſet of wooden pins fixed into the wall, near the dreſſer, ſometimes to the amount of a hundred, in order to undergo the finiſhing operations. This workman, who is always the moſt expert and ſkilful in all the different branches carried on at the foundery, begins by taking one of theſe ſticks, and, with a peculiar addreſs, ſlides the whole column of types off upon the dreſſing-ſtick: this is made of well-ſeaſoned mahogany, and furniſhed with two end-pieces of ſteel, a little lower than the body of the types, one of which is moveable, ſo as to approach the other by means of a long ſcrew-pin, inſerted in the end of the ſtick. The types are put into this ſtick with their faces next to the back or projection; and after they are adjuſted to one another ſo as to ſtand even when they are bound up, by ſcrewing home the moveable end-piece. It is here where the great and requiſite accuracy of the moulds comes to be perceived; for in this caſe the whole column, ſo bound up, lies flat and true upon the ſtick, the two extreme types being quite parallel, and the whole has the appearance of one ſolid continuous plate of metal. The leaſt inaccuracy in the exact paralleliſm of the individual type, when multiplied ſo many times, would render it impoſſible to bind them up in this manner, by diſpoſing them to riſe or ſpring from the ſtick by the ſmalleſt preſſure from the ſcrew. Now, when lying ſo conveniently with the narrow edges uppermoſt, which cannot poſſibly be ſmoothed in the manner before mentioned by the ſtones, the workman does this more effectually by ſcraping the ſurface of the column with a thick-edged but ſharp razor, which at every ſtroke brings on a very fine ſmooth ſkin, like to poliſhed ſilver; and thus he proceeds till in about half a minute he comes to the farther end of the ſtick. The other edges of the types are next turned upwards, and poliſhed in the ſame manner. It is whilſt the types thus lie in the dreſſing-ſtick that the operation of bearding or barbing is performed, which is effected by running a plane, faced with ſteel, along the ſhoulder of the body next to the face, which takes more or leſs off the corner, as occaſion may require. Whilſt in the dreſſing-ſtick they are alſo grooved, which is a very material operation. In order to underſtand this, it muſt be remembered, that when the types are firſt broken off from the jets, ſome ſuperfluous metal always remains, which would make them bear very unequally againſt the paper whilſt under the printing-preſs, and effectually mar the impreſſion. That all theſe inequalities may, therefore, be taken away, and that the bearings of every type may be regulated by the ſhoulders imparted to them all alike from the mould, the workman or dreſſer proceeds in the following manner. The types being ſcrewed up in the ſtick, as before mentioned, with the jet-end outermoſt, and projecting beyond the wood about one eighth of an inch, the ſtick is put into an open preſs, ſo as to preſent the jet-end uppermoſt, and then every thing is made faſt by driving a long wedge, which bears upon a ſlip of wood, which lies cloſe to the types the whole length: then a plough or plane is applied, which is ſo conſtructed as to embrace the projecting part of the types betwixt its long ſides, which are made of poliſhed iron. When the plane is thus applied, the ſteel cutter bearing upon that part between the ſhoulders of the types, where the inequalities lie, the dreſſer dextrouſly glides it along, and by this means ſtrips off every irregular part that comes in the way, and ſo makes an uniform groove the whole length, and leaves the two ſhoulders ſtanding; by which means every type becomes preciſely like to another, as to the height againſt paper. The types being now finiſhed, the ſtick is taken out of the preſs, and the whole column replaced upon the other ſtick; and after the whole are ſo dreſſed, he proceeds to pick out the bad letters, previouſly to putting them up into pages and papers. In doing this he takes the ſtick into his left hand, and turning the faces near to the light, he examines them carefully, and whenever an imperfect or damaged letter occurs, he nimbly plucks it out with a ſharp bodkin, which he holds in the right hand for that purpoſe. Thoſe letters which, from their form, project over the body

of

of the type, and which cannot on this account be rubbed on the ſtones, are ſcraped on the broad-ſides with a knife or file, and ſome of the metal next the face pared away with a pen-knife, in order to allow the type to come cloſe to any other. This operation is called kerning.

The excellence of printing types conſiſts not only in the due performance of all the operations above deſcribed, but alſo in the hardneſs of the metal, form, and fine proportion of the character, and in the exact bearing and ranging of the letters in relation to one another.

FOUNDERY, *Military*. Under the ſeveral appropriate heads, we have furniſhed information regarding the ſeveral kinds of foundery neceſſary to the eſtabliſhment of that variety of profeſſions, wherein caſtings of different kinds, whether in metal, wax, plaſter, &c. are deſiderata: we now have to offer a few remarks on ſuch as appertain more particularly to the ſupply of our arſenals.

The caſting of cannon, ſhot, &c. was, until about half a century ago, conſidered an arduous undertaking; and ſo little were the fundamental principles of the art underſtood, that we are aſſured not one in three of the ſhells caſt for the mortar ſervice could be admitted into the ſtores. Such have been the improvements made, that thouſands of articles, which uſed to be from neceſſity made of wrought iron, are now to be had from the founderies at leſs than one-fifth of their former prices; while the material itſelf has been ſo highly perfected, that inſtances have been known of caſt-iron being ſufficiently ſoft to bear the file, and ſufficiently ductile to undergo the hammer. Such, indeed, could not be done but at conſiderable expence; nor does it appear that much good could reſult in general. With reſpect to military apparatus, it is found expedient to have the whole of our cannon, mortars, carronades, ſhot, ſhells, and garriſon gun-carriages, caſt at the ſeveral founderies eſtabliſhed in the vicinity of coal and iron mines; whereby the work is done at comparatively a low expence, and the articles can be conveyed by water to the warren at Woolwich much under the prices at which they could be caſt at the place, to which both the iron and the coals muſt be tranſported.

The French have, ſince the commencement of the revolution, ſhewn what may be effected in this branch of military economy, by a people determined to overcome every difficulty, and to apply their reſources, whether public or private, towards national purpoſes. It is a well aſcertained fact, that in ſeveral of the departments of France, from which the trains of artillery, together with the ſeveral ſtores appertaining to them, had been withdrawn, the people ſupplied their national guards with field-pieces caſt in ſmall temporary founderies, where the furnaces were rarely equal to heating more than from twenty to thirty pounds of bell-metal, &c. of which the ſacred edifices, &c. throughout the country had been ſtripped. By a due combination of the whole, very ſerviceable cannon, and eſpecially howitzers, which ſeem to be a favourite ſpecies of artillery among the French, were thus ſupplied.

Though it muſt be admitted that a foundery ſuited to caſting cannon, of any deſcription, could not be attached to the ordnance department of armies ſerving out of the kingdom, we are inclined to hazard the opinion, that ſmall laboratory furnaces, adequate to the caſting of ſhot and grape, but eſpecially of muſket balls, might be annexed thereto. In ſome inſtances, when the ſtock of grape-ſhot has been expended, it has become neceſſary to make caſe-ſhot of muſket balls, whereby the infantry have been very ill ſupplied with ammunition. If, in ſuch inſtances, portable furnaces, and crucibles, together with proper moulds, have been at hand, (for the whole might be conveyed in a waggon, or perhaps in a cart,) abundance of refuſe iron could have been formed into grape-ſhot; and there would have been no ſcarcity of muſket ammunition.

Nor can we ſee any objection to the ſupply of proper materials for eſtabliſhing founderies, ſuited to caſting field-pieces, being ſhipped with extenſive armaments proceeding on foreign ſervice; ſince the ſpace they would occupy muſt be far leſs than is required for that immenſe quantity of ſtores neceſſarily ſent to places where no foundery exiſts. Hence tonnage, time, and treaſure, are often laviſhly expended. The caſting of ſhot and ſhells, in ſuch ſituations, would generally prove eaſy, and liberate many a tranſport from the conveyance of ſuch dead-weight, as not only precludes the ſupply of other equally neceſſary ſtores, but, in many inſtances, riſks, or even cauſes, a total loſs.

FOUNDLING HOSPITAL. See *Foundling* HOSPITAL.

FOUN-HING, in *Geography*, a town of China, of the ſecond rank, in the province of Fo-kien; 175 miles E.S.E. of Peking. N. lat. 26° 54′. E. long. 119° 49′.

FOUN-IM, a town of China, of the third rank, in the province of Pe-tche-li; 20 miles E. of Young-ping.

FOUNT, or FONT, among *Printers*, &c. a ſet, or quantity, of characters, or letters, of each kind, caſt by a letter-founder, and ſorted.

We ſay, a founder has caſt a fount of pica, of Engliſh, of pearl, &c. meaning that he has caſt a ſet of characters of theſe kinds.

A complete fount does not only include the running letter, but alſo majuſcules, or large and ſmall capitals, ſingle letters, double letters, points, commas, lines, borders, head-pieces, tail-pieces, and numeral characters.

Founts are large or ſmall, according to the demand of the printer, who orders them by the hundred weight, or by ſheets. When the printer orders a fount of five hundred, he means that the fount ſhould weigh five hundred pounds. When he demands a fount of ten ſheets, it is underſtood, that with that fount he ſhall be able to compoſe ten ſheets, or twenty forms, without being obliged to diſtribute. The founder takes his meaſures accordingly: he reckons a hundred and twenty pounds for a ſheet, including the quadrates, &c. or ſixty pounds for a form, which is half a ſheet: not that the ſheet always weighs a hundred and twenty pounds, or the form ſixty pounds; on the contrary, it varies according to the ſize of the form; beſides, it is always ſuppoſed that there are letters left in the caſes.

The letter-founders have a kind of liſt, or tariff, whereby they regulate their founts: the occaſion of which is, that ſome letters being in much more uſe, and oftener repeated, than others, their cells, or caſes, ſhould be better filled and ſtored, than thoſe of the letters which do not return ſo frequently.

Thus the *o*, and *i*, for inſtance, are always in greater quantity than the *k*, or *z*.

This difference will be beſt perceived from a proportional compariſon of thoſe letters with themſelves, or ſome others. Suppoſe a fount of a hundred thouſand characters, which is a common fount: here the *a* ſhould have five thouſand; the *c*, three thouſand; the *e*, eleven thouſand; the *i*, ſix thouſand; the *m*, three thouſand; the *k*, only thirty; and the *x*, *y*, and *z*, not many more. But this is only to be underſtood of the letters of the lower caſe; thoſe of the upper caſe having other proportions, which it would be here too long to inſiſt on.

FOUNTAIN, FONS, in *Philoſophy*, a ſpring, or ſource, of water, riſing out of the ground.

For

For the phenomena, theory, origin, &c. of ſprings, or fountains, ſee SPRING.

Among the ancients, the fountains, or ſources of rivers, were held ſacred, and even worſhipped, as a kind of divinities.

Seneca obſerves as much, in his forty-firſt epiſtle; and Cicero, lib. iii. De Nat. Deor. cap. 20. mentions, that the Roman prieſts, and augurs, uſed, in their prayers and invocations, to call on the names of the Tyber, and other rivers, brooks, and ſprings, about Rome. And the ſeventh inſcription, in p. 94. of Gruter, has *FONTI* DIVINO ET GENIO NVMINIS *FONTIS*.

It was a point of religion, not to diſturb, or make muddy, theſe waters in waſhing or bathing. Tacitus gives an inſtance hereof in Nero, Annal. lib. xiv. cap. 22.

FOUNTAIN, or *Artificial Fountain*, in *Hydraulics*, a machine or contrivance, whereby water is violently ſpouted, or darted up; called alſo a *jet d'eau*. See JET *d'Eau*, FLUID, &c.

There are divers kinds of artificial fountains; ſome founded on the ſpring, or elaſticity, of the air; and others, on the preſſure, or weight, of the water, &c.

The ſtructure of each of theſe, being pretty and curious, and affording a good illuſtration of the doctrine of hydraulics, and pneumatics, ſhall be here explained.

The theory of fountains may be collected from the articles AIR, FLUID, &c. and other particulars relating to their ajutages, and pipes of conduct, &c. may be found under JET *d'Eau*, and *Motion of* WATER.

FOUNTAIN. *Conſtruction of an artificial Fountain, playing by the ſpring, or elaſticity of the air.*—A veſſel, proper for a reſervoir, as A B, *Plate* VI. *Hydraulics*, *fig.* 7. is provided, of metal, glaſs, or the like, ending in a ſmall neck *c*, at the top; through this neck a tube is put *c d*, traverſing the middle of the veſſel, till its lower orifice *d*, nearly, but not abſolutely, reach the bottom of the veſſel; the veſſel being firſt half filled with water. The neck is ſo contrived, as that a ſyringe, or condenſing pipe, may be ſcrewed upon the tube; by means whereof a large quantity of air may be intruded through the tube into the water, out of which it will diſengage itſelf, and emerge into the vacant part of the veſſel, and lie over the ſurface of the water C D.

Now, the water here contained being thus preſſed by the air, which is, *e. gr.* twice as denſe as the external air, and the elaſtic force of air being equal to its gravitating force; the effect will be the ſame, as if the weight of the column of air over the ſurface of the water were double that of the column preſſing in the tube; ſo that the water muſt, of neceſſity, ſpout up, through the tube, when the ſyringe is removed, with a force equal to the exceſs of preſſure of the included, above that of the external air.

FOUNTAIN. *Conſtruction of an artificial Fountain, playing by the preſſure of the water.*—Having the conveniency of a fund, or reſervoir of water, in a place conſiderably higher than that where the fountain is to be (whether that fund hath been placed there by nature, or whether it hath been raiſed for the purpoſe, by a proper engine, as a pump, ſiphon, ſpiral ſcrew, or the like): from the reſervoir lay vertical tubes, for the water to deſcend through; and to theſe vertical tubes, fit other horizontal ones, under ground, to carry the water to the place where the fountain is to play. Laſtly, from theſe horizontal tubes, erect other vertical ones, by way of ajutages, jets, or ſpouts, their altitude being much leſs than that of the tubes whereby the water was carried to the horizontal ones.

Then will the water, by the preſſure of the ſuperincumbent column, be ſpouted up at theſe jets; and that to the height or level of the water in the reſervoir; and this will be the caſe, howſoever any of the tubes be bent or incurvated. For the demonſtration, ſee FLUIDS.

Thus may water be ſpouted to any given height at pleaſure; and the tubes may be ſo proportioned as to yield any given quantity of water, in a given time; or ſeveral tubes, or the ſame fountain, may be made to yield water in any given ratio; or, laſtly, different tubes may project the water to different altitudes. Rules for all which the reader will find among the laws of FLUIDS and JETS *d'Eau*.

Theſe aerial or aquatic fountains may be applied in various manners, ſo as to exhibit various appearances; and, from theſe alone, ariſes the greateſt part of our artificial water-works. An inſtance, or two, will not be unamuſing.

FOUNTAIN *ſpouting the water in various directions.*—Suppoſe the vertical tube, or ſpout, in which the water riſes, to be A B (*Plate* VI. *Hydraulics*, *fig.* 8.) into this fit ſeveral other tubes; ſome horizontal, others oblique; ſome inclining, others reclining, as O P, M N, F L, &c.

Then, as all water retains the direction of the aperture through which it is ſpouted, that iſſuing through A will riſe perpendicularly; and that through L, H, N, P, E, will deſcribe arches of different magnitudes, and tending different ways.

Or thus: ſuppoſe the vertical tube A B, *fig.* 9. through which the water riſes, to be ſtopped at the top, as in A; and, inſtead of pipes, or jets, let it be only perforated with little holes all round, or only round half its ſurface; then will the water ſpin forth, in all directions, through the little apertures, and to a diſtance proportional to the height of the fall of the water.

And hence, if the tube A B be ſuppoſed the height of a man, and be furniſhed with an epiſtomium, or cock, at C, upon opening the cock, the ſpectators will be covered unexpectedly with a ſhower.

It muſt be here obſerved, that the diameters of the apertures by which the water is emitted, muſt be conſiderably leſs than thoſe of the tubes in which the water is brought; leſt the reſiſtance of the air, and other impediments, ſpecified under FLUID and JET *d'Eau*, break the force of the water.

FOUNTAIN *playing by the draught of the breath.*—Suppoſe A B, *fig.* 10. a glaſs, or metalline ſphere, wherein is fitted a tube C D, having a little orifice in C, and reaching almoſt to D, the bottom of the ſphere. If, now, the air be ſucked out of the tube C D, and the orifice C be immediately immerged under cold water, the water will aſcend through the tube into the ſphere.

Thus proceeding, by repeated exſuctions, till the veſſel be above half full of water; and then applying the mouth to C, and blowing air into the tube, upon removing the mouth, the water will ſpout forth.

Or, if the ſphere be put in hot water, the air, being thereby rarefied, will make the water ſpout as before.

This kind of fountain is called *Pila Heronis*, or Hero's ball, from the name of its inventor.

FOUNTAIN, *the ſtream whereof raiſes and plays a braſs ball.*—Provide a hollow braſs ball A, *fig.* 11. made of a thin plate, that its weight may not be too great for the force of the water. Let the tube B C, through which the water riſes, be exactly perpendicular to the horizon.

Then the ball, being laid in the bottom of the cup, or baſon B, will be taken up in the ſtream, and ſuſtained at a conſiderable height, as A, alternately vibrating, or playing up and down.

Hence,

Hence, as the figure of the ball contributes nothing to its reciprocal riſe and fall, any other body, not too heavy, may be ſubſtituted in lieu thereof; *e. gr.* a bird, with its wings ſtretched forth.

But note, that, as it is neceſſary the ball, when on the deſcent, ſhould keep the ſame preciſe perpendicular wherein it roſe (ſince, otherwiſe, it would miſs the ſtream, and fall downright), ſuch a fountain can only be played in a place free from wind.

FOUNTAIN *which ſpouts water in form of a ſhower.*—To the tube wherein the water is to riſe, fit a ſpherical, or lenticular head, A B, *fig.* 12. made of a plate of metal, and perforated at the top with a great number of little holes.

The water riſing with vehemence towards A B, will be there divided into innumerable little threads, and afterwards broke, and diſperſed into the fineſt drops.

FOUNTAIN *which ſpreads the water in form of a table cloth.*—To the tube A B, *fig.* 13. ſolder two ſpherical ſegments, C and D, almoſt touching each other, with a ſcrew E, to contract or amplify the interſtice or chink, at pleaſure.

Others chuſe to make a ſmooth, even cleft, in a ſpherical or lenticular head, fitted upon the tube.

The water ſpouting through this chink or cleft will expand itſelf in manner of a cloth.

FOUNTAINS, *wherein the water ſpouts out of the figures of men, and other animals.*—Since water may be derived, or conveyed, by tubes in any ſituation, and always retains the direction of the aperture, all here required is, to incloſe tubes within the figures of men, or other animals, having their orifices in thoſe parts whence the water is intended to ſpout forth.

From the principles hitherto laid down, it will be very eaſy to deduce whatever relates to the furniture of fountains, and the various forms water may be put into by their means; all depending on the magnitude, figure, and direction, of the ajutages, or apertures.

FOUNTAIN, *which, when it has done ſpouting, may be turned like an hour-glaſs.*—Provide two veſſels, A and B, *Plate* VII. *Hydraulics, fig.* 1. to be ſo much the bigger as the fountain is to play the longer; and placed at ſo much the greater diſtance from each other, as the water is deſired to ſpout the higher. Let C D E be a crooked tube, furniſhed in E with a jet; and G H I another bent tube, furniſhed with a jet in I; K L and G F are to be the other leſſer tubes, open at both ends, and reaching near to the bottom of the veſſels B and A, to which the tubes G H and C D are likewiſe to reach.

If, now, the veſſel A be filled with water, it will deſcend through the tube C D; and will ſpout up through the jet E, by the preſſure of the column of water C D. But unleſs the pipe G F was open at G, to let the air run up to F, and preſs at the top of the ſurface of the water in the cavity A, the water could not run down and ſpout at E. After its fall again, it will ſink through the little tube K L, into the veſſel B, and expel the air through the tube G I. At length, when all the water is emptied out of the veſſel A, by turning the machine upſide down, the veſſel B will be the reſervoir, and make the water ſpout up through the jet I, the pipe K L ſupplying B with air to let the water deſcend in the direction G H I.

Hence, if the veſſels A and B contain juſt as much water as will be ſpouted up in an hour's time, we ſhall have a ſpouting clepſydra or water-clock; which may be graduated, or divided, into quarters, minutes, &c. as ſhewn under CLEPSYDRA.

FOUNTAIN *of Command.*—This depends on the ſame principles with thoſe of the former: C A E, *fig.* 2. is a veſſel of water ſecured againſt the entrance of the air, except through the pipe G F, when the cock C, by which it was filled, is ſhut. There is another pipe E D H B, which goes from the bottom of the water to the jet B in the baſon D B, but this is ſtopped by the cock H. At the loweſt part of the baſon D B there is a ſmall hole at I to let the water of the baſon D B run into the baſon G H under it: there is alſo a ſmall triangular hole, or notch, in the bottom of the pipe F G at G. Turn the cock H, and the fountain will play for ſome time, then ſtop, then play again alternately for ſeveral times together. When thoſe times of playing and ſtopping are known before-hand, you may command the fountain to play or ſtop, whence its name. The cauſe of this phenomenon is as follows: the water coming down the pipe E D H B, would not come out at B, if the air S s, above the water, was not ſupplied as it dilated: now it is ſupplied by the pipe G F, which takes it in at the notch G, and delivers it out at F; but after ſome time the water, which has ſpouted out at B, falling down into the baſon D B, riſes high enough to come above the notch G, which ſtops the paſſage of the air; ſo that the air S s, above the water in the veſſel C A E, wanting a ſupply, cannot ſufficiently preſs, and the fountain ceaſes playing. But when the water of D E has run down into the lower baſon H G, through the hole I, till it falls below the top of the notch G, the air runs up into the upper receptacle, and ſupplies that at S s, and the fountain plays again. This is ſeen a little before-hand, by a ſkin of water on the notch G, before the air finds a paſſage, and then you may command the fountain to play. It is evident, that the hole I muſt be leſs than the hole of the jet, or elſe all the water would run out into the lower baſon, without riſing high enough to ſtop the notch G.

FOUNTAIN *that begins to play upon the lighting of candles, and ceaſes as they go out.*—Provide two cylindrical veſſels, A B and C D, *fig.* 3. connect them by tubes, open at both ends, K L, B E, &c. ſo that the air may deſcend out of the higher into the lower: to the tubes ſolder candleſticks, H, &c. and to the hollow cover of the lower veſſel, C E, fit a little tube, or jet, F G, furniſhed with a cock G, and reaching almoſt to the bottom of the veſſel. In G let there be an aperture, furniſhed with a ſcrew, whereby water may be poured into C D.

Then, upon lighting the candles H, &c. the air in the contiguous tubes becoming rarefied thereby, the water will begin to ſpout through G F.

By the ſame contrivance may a ſtatue be made to ſhed tears upon the preſence of the ſun, or on the lighting of a candle, &c.: all here required being only to lay tubes from the cavity wherein the air is rarefied, to ſome other cavities placed near the eyes full of water.

A fountain may be made by the rarefaction of the air in the following manner: let A B and C D, *fig.* 4. be two pipes fixed to a braſs head C, made to ſcrew into a glaſs veſſel E, which, having a little water in it, is inverted till the pipes are ſcrewed on; then reverting it ſuddenly, ſo as to put A, the lower end of the ſpouting pipe A B, into a jar of water A, and the lower end of the deſcending pipe C D, into a receiving veſſel D, the water will ſpout up from the jar A into the tall glaſs veſſel E, from which it will go down at the mouth C through C D, into the veſſel D, till the water is wholly emptied out of A, making a fountain in E, into D. The reaſon of the play of the fountain is this: the pipe C D, being two feet nine inches long, lets down a column of water which rarefies the air $\frac{1}{12}$th part in

in the veſſel E, where it preſſes againſt the water ſpouting at B with $\frac{1}{12}$th of the force by which the water is puſhed up at the hole A, by the preſſure of the common air on the water in the veſſel A; ſo that the water ſpouts up into E, when the air is rarefied $\frac{1}{12}$, with the difference of the preſſure of the atmoſphere, and the forementioned rarefied air; *i. e.* of 33 to $2\frac{3}{4}$. This would raiſe the water two feet nine inches; but the length of the pipe A, nine inches being deducted, the jet will only riſe two feet. This, ſays Deſaguliers, may be called a ſyphon fountain, where A B is the driving leg, and C D the iſſuing leg.

Fountain *of Hero of Alexandria*, ſo called, becauſe it was contrived by him. In the firſt fountain already deſcribed, the air is compreſſed by a ſyringe; in this, ſee *fig.* 5, the air, being only compreſſed by the concealed fall of water, makes a jet, which, after ſome continuance, is conſidered by the ignorant as a perpetual motion; becauſe they imagine that the ſame water which fell from the jet riſes again. The boxes C E and D Y X, being cloſe, we ſee only the baſon A B W, with a hole at W, into which the water ſpouting at B falls: but that water does not come again; for it runs down through the pipe W X into the box D Y X, from whence it drives out the air, through the aſcending pipe Y Z, into the cavity of the box C E, where, preſſing upon the water that is in it, it forces it out through the ſpouting pipe O B, as long as there is any water in C E; ſo that this whole play is only whilſt the water contained in C E, having ſpouted out, falls down through the pipe W X into the cavity D Y X. The force of the jet is proportional to the height of the pipe W X, or of the boxes C E and D Y above one another; the height of the water, meaſured from the baſon A B W to the ſurface of the water in the lower box D Y X, is always equal to the height meaſured from the top of the jet to the ſurface of the water in the middle cavity at C E. Now, ſince the ſurface C E is always falling, and the water in D Y always riſing; the height of the jet muſt continually decreaſe, till it is ſhorter by the height of the depth of the cavity C E, which is emptying, added to the depth of the cavity D Y which is always filling; and when the jet is fallen ſo low it immediately ceaſes. The air is repreſented by the points in this figure. To prepare this fountain for playing, which ſhould be done unobſerved, pour in water at W, till the cavity D X Y is filled; then invert the fountain, and the water will run from the cavity D X Y into the cavity C E, which may be known to be full, when the water runs out at B held down. Set the fountain up again, and, in order to make it play, pour in about a pint of water into the baſon A B W; and as ſoon as it has filled the pipe W X, it will begin to play, and continue as long as there is any water in C E. You may then pour back the water left in the baſon A B W, into any veſſel, and invert the fountain, which being ſet up right again, will be made to play, by putting back the water poured out into A B W; and ſo on as often as you pleaſe.

The fountain, *fig.* 6. is of the ſame kind; but having double the number of pipes and concealed cavities, it plays as high again. In order to underſtand its ſtructure, ſee *fig.* 7. The baſon is A, the four cavities are B, C, D, and E, from which the water through the pipe f G, ſpouts up to double the height of the fountain, the air at E, which drives it, being doubly condenſed. The water going down the pipe 1 (*e. gr.* three feet long), condenſes the air that goes up into the cavity C through the pipe 2, ſo as to to make it $\frac{1}{10}$ ſtronger than the common air; then the water which falling into the pipe 3 from C to D, is capable, by the height of its fall, of condenſing the air at E, ſo as to make it $\frac{1}{10}$ ſtronger, being puſhed at C by air already condenſed into $\frac{1}{10}$ leſs ſpace, cauſes the air at E to be condenſed twice as much; that is, to be $\frac{1}{5}$ ſtronger than common air; and, therefore, it will make the water at G ſpout out with twice the force, and riſe twice as high as it would do, if the fountain had been of the ſame ſtructure as the former. In playing this fountain, turn it upſide down, and taking out the plugs g, h, fill the two cavities C and E, and, having ſhut the holes again, ſet the fountain upright, and pour ſome water into the baſon A, and the jet will play out at G; but the fountain will begin to play too ſoon; and, therefore, the beſt way is to have a cock in the pipe 3, which, being open, whilſt the cavities C and E are filled, and ſhut again before the fountain is ſet up, will keep the water thrown into the baſon from going down the pipe 1, and that of the cavity C from going down the pipe 3, by which means the fountain will not play before its time, which will be as ſoon as the cock is opened.

Fountain, *Dial, of Deſaguliers*, is contrived to play by the ſpring of the air, increaſed by the heat of the ſun, and ſerves alſo for a dial at the ſame time. G N S, *fig.* 8, is a hollow globe of thin copper, eighteen inches in diameter, ſupported by a ſmall inverted baſon, reſting on a frame A B C, with four legs, between which there is a large baſon of two feet diameter. In the leg C there is a concealed pipe, proceeding from G, the bottom of the inſide of the globe, along H V, and joining an upright pipe u I, for making a jet at I. The ſhort pipe I u, going to the bottom of the baſon, has a valve at u, under the horizontal part H V, and another valve at V above it, and under the cock &. At the north pole N there is a ſcrew for opening a hole, through which the globe is ſupplied with water. When the globe is half filled, let the machine be ſet in a garden, and, as the ſun heats the copper and rarefies the included air, the air will preſs upon the water, which, deſcending through the pipe G C H V, will lift up the valve V, and ſhut the valve u, and the cock being open, ſpout out at I, and continue to do ſo for a long time, if the ſun ſhines, and the ajutage be ſmall. At night, as the air condenſes again by the cold, the outward air, preſſing into the ajutage I, will ſhut the valve N, but by its preſſure on the baſon D u H, puſh up the water, which has been played in the day-time through the valve u, and the pipe u H G into the globe, ſo as to fill it up again to the ſame height which it had at firſt, and the next ſun-ſhine will cauſe the fountain to play again, &c. The uſe of the cock is to keep the fountain from playing till you think proper: a ſmall jet will play ſix or eight hours. If the globe be ſet for the latitude of the place, and rectified before it be fixed, with the hour lines or meridians drawn upon it, the hours marked, and the countries painted upon it, as in the common globe, it will be a good dial; the ſun ſhining upon the ſame places in this globe as it does upon the earth itſelf. Deſaguliér's Exper. Phil. vol. ii. lect. 9. p. 205.

Fountain, with regard to *Architecture*, is an aſſemblage of maſonry, ſculpture, &c. either for the decoration, or conveniency of a city, garden, or the like.

Fountains acquire various denominations, according to their form and ſituation: as,

Fountain, *Arched*, that whoſe baſon and jet are placed perpendicularly under the arch. Such are the fountains of the Colonade, and the triumphal water-arch at Verſailles.

Fountain, *Baſon*, is that with only a ſimple baſon of any figure whatever; in the middle whereof is a jet or ſpout, or perhaps a ſtatue, or even a group of figures.

Such

Such was formerly the fountain in the court of Buckingham-houſe.

Fountain, *Covered*, a kind of pavilion, built of ſtone, either inſulate, and ſquare, or round, or multilateral, or backed; and that either, with a projecture, or indenture, incloſing a reſervoir, and ſpouting or darting forth the water thereof through one or more cocks, in the middle of a ſtreet, ſquare, garden, court, or the like. Such was that in Lincoln's-inn New Square, London.

Fountain, *Cup*, is that which, beſides a baſon, has likewiſe a cup of one ſingle piece of ſtone, or marble, ſupported on a ſhaft or pedeſtal, and receiving a jet, or ſpout, riſing out of the middle thereof.

As the fountain in the court of the Vatican, the cup whereof is of granite, and antique, being brought from the baths of Titus at Rome.

Fountain, *Marine*, that compoſed of aquatic figures, as ſea divinities, naiads, tritons, rivers, dolphins, and other fiſhes, and ſhells. Such is the fountain of the palace of Paleſtrina at Rome, where the ſhell, ſupported by four dolphins, ſerves as a cup, and ſupports a triton, that ſpouts water out of his concha marina.

Fountain, *Naval*, is that made in the form of a veſſel. Such is that of the place D'Eſpagne, at Paris, repreſenting a bark: that at Monte-Cavello, repreſenting a galley: or that before the vineyard Mattei, at Rome, reſembling a boat.

Fountain, *Open*, is any ſpouting fountain with a baſon, cup, or other ornaments, all open; ſuch as are met with frequently in our gardens, and in the vineyards at Rome.

Fountain, *Pyramidal*, that formed of ſeveral baſons, or cups, ranged in ſtories over each other, and diminiſhing all the way, being ſupported by a hollow ſtem, or ſhaft. As the fountain of Monte-Dragone at Freſcati.

Or elſe ſupported by figures, fiſhes, or conſoles; the water whereof, in its fall, makes nets in divers ſtories, and repreſents a kind of water pyramid; as that at the head of the caſcades at Verſailles.

Fountain, *Ruſtic*, is that formed, or enriched, with rock-work, ſhell-work, petrifactions, &c.

Fountain, *Satyric*, is a kind of ruſtic fountain, in the manner of a grotto, adorned with termini, maſcaroons, fauns, ſylvans, bacchantes, and other ſatyrical figures, ſerving for ornaments, as well as jets d'eau.

Fountain, *Spouting*, or *jet d'eau*, is any fountain, whoſe water is darted forth impetuouſly through one or more jets, or ajutages, and returns in form of rains, nets, folds, or the like. See Jet *d'Eau*.

Fountain, *Spring*, a kind of plain ſpout, or ſtream of water, iſſuing out of ſtone, or a hole in a wall, without any decoration. Such is the fountain of Trevi at Rome.

Foutainn, *Statuary*, that which, being opened and inſulated, or even-backed, is adorned with one or more ſtatues, by way of finiſhing or crowning; as the fountain of Latona, at Verſailles; and that at the Shepherd at Caprarola.

There are alſo ſtatues which ſpout forth water at ſome of their parts; or at ſea-ſhells, vaſes, urns, and other attributes of the ſea.

Fountain, *Symbolical*, that where the principal ornaments are the attributes, arms, or cognizance, of the perſon who erected it. Such are the fountain of St. Peter in Montorio, reſembling a caſtle flanked with towers, and donjons, repreſenting the arms of Caſtile; and ſome other fountains at Rome, among which are the fleur-de-lis, and the dove, the bearings of the family of pope Innocent X.

Fountain-*pen*, is a ſort of pen contrived to contain a great quantity of ink, and let it flow, by gentle degrees, ſo as to ſupply the writer a long time without the neceſſity of taking freſh ink.

The fountain-pen, repreſented *Plate* XV. *Miſcellan. fig.* 4. conſiſts of divers pieces, F, G, H, of braſs, ſilver, &c. whereof the middle piece F carries the pen, which is ſcrewed into the inſide of a little pipe; which, again, is ſoldered to another pipe of the ſame bigneſs, as the lid G; in which lid is ſoldered a male ſcrew, for ſcrewing on the cover; as alſo for ſtopping a little hole at the place, and hindering the ink from paſſing through it: at the other end of the piece F is a little pipe, on the outſide whereof the top cover H may be ſcrewed. In the cover there goes a port-craion, to be ſcrewed into the laſt-mentioned pipe, in order to ſtop the end of the pipe into which the ink is to be poured by a funnel.

To uſe the pen, the cover G muſt be taken off, and the pen a little ſhaken, to make the ink run more freely.

FOUNTAINE, *Sir* Andrew, in *Biography*, an Engliſh antiquary, collector, and writer, was born at Norford in the county of Norfolk, and received his education at Chriſt-church college, Oxford, where he early diſtinguiſhed himſelf by his proficiency in Anglo-Saxon literature. Leaving the ſeat of the muſes to reſide on his eſtate, he erected a noble houſe, which became celebrated by the literary characters of the time, whoſe acquaintance the proprietor aſſiduouſly cultivated, and who were frequently entertained, as welcome gueſts, in his hoſpitable manſion. Among others were Swift, Addiſon, and Pope. By the latter ſir Andrew was complimented for his elegant taſte, and his reſidence continued to perpetuate a diſplay of it. Norford-hall was not only the rendezvous of living genius, but a repoſitory of arts and learning. Its owner evinced a love of the fine arts, and exhibited ſpecimens of his own attainments. The admirable deſigns for illuſtrating the Tale of a Tub he drew for Swift, with whom he was very intimate. He made a collection of choice pictures, ancient painted earthen ware, bronzes, ſtatues, coins, and numerous ſpecimens of curious antiquated remains; and ſtocked a large, handſome library with a fine ſelection of rare, valuable books and manuſcripts.

The founder of this repoſitory of the arts was made knight of the Bath by patent, during the reign of George the firſt, in 1726: and in the following year was appointed warden of the mint. He died in 1753. His treatiſe, entitled "Numiſmata Anglo-Saxonica, et Anglo-Danica, breviter illuſtrata," was printed in Hickes's Theſaurus, at Oxford, in 1704. Gen. Biog. Dict. and Blomefield's Hiſtory of Norfolk.

FOU-PIM, in *Geography*, a town of China, in the province of Pe-tche-li; 63 miles W. of Paoting.

FOU-PIN, a town of China, of the third rank, in the province of Quang-tong; 12 miles S.E. of Yao.

FOUQUIERES, James, in *Biography*, a landſcape painter, born at Antwerp in 1580. He ſoon quitted the ſtyle of Brughel, under whom he early in life ſtudied, and reſiding ſome time at Rome and Venice, imbibed a taſte for a more exalted view of nature, and mode of imitating her productions.

He ſtudied the works of Titian, and obtained very much of his grand ſtyle of compoſition and execution, though in the latter he was more ſharp, and had more of

what among artiſts is peculiarly denominated manner of touch, than his prototype, that great maſter of art.

Fouquieres was an excellent painter, and deſervedly gained a great reputation. He painted both in a large and ſmall ſtyle equally well, with a beautiful taſte in arrangement and effect, and with great force. Sometimes his colour is too green to be perfect, but in general it is very rich and pleaſing.

He was engaged and much careſſed at the court of the elector Palatine, and afterwards ſpent ſeveral years of his life in France, where his works met with univerſal approbation, and he was proportionally well paid for his paintings. Unhappily he ſunk at laſt into poverty, and died in the year 1659 in the houſe of an inconſiderable painter named Silvain, who lived in the ſuburbs of Paris.

FOUR Brothers, in *Geography*, four ſmall iſlands in the Eaſt Indian ſea. S. lat. 6° 54′. E. long. 115° 22′.

Four *Corners*, in the *Manege*, or to work upon the four corners, is to divide in imagination the volt or round into four quarters; ſo that, upon each of theſe quarters, the horſe makes a round or two at trot or gallop: and when he has done ſo upon each quarter, he has made the four-corners.

Four, *Cul de four*. See Cul.

Four *Evangeliſts*, in *Geography*. See Evangelists.

Four *Iſlands*, a cluſter of ſmall iſlands in the Pacific ocean, ſo called by lieutenant Shortland. S. lat. 4° 50′. E. long. 155° 36′.

Four *Keys*, ſmall iſlands in the bay of Honduras. N. lat. 17° 12′. W. long. 87° 55′.

Four *Mile Water*, a river of Ireland, which runs into Dunmannus bay, five miles S.W. of Bantry.

Four *Mile Creek*, a river of Kentucky, in America, which runs into the Ohio. N. lat. 36° 50′. W. long. 89° 30′.—Alſo, a river of Virginia, which runs into the Potomack. N. lat. 38° 56′. W. long. 77° 13′.

Four *Saddle Iſland*, an iſland in the Mergui Archipelago, about ſix miles in circumference, ſeparated by Alderſey's ſtraits from the ſouthern extremity of the iſland of St. Suſanna. N. lat. 10° 27′.

FOURCA, a town of Africa, in the kingdom of Hoval; 35 miles W. of Ender.

FOURCES, a town of France, in the department of the Gers; ſix miles W.N.W. of Condom.

FOURCHE, a river of North America, which runs into lake Michigan. N. lat. 44° 31′. W. long. 86° 38′.

FOURCHEE, or Fourchy, in *Heraldry*, denotes a croſs forked at the ends.

Upton rather repreſents it as anchored, the extremities turning in a circular manner to ſharp points; whereas the true croſs fourchee, *i. e.* forked, has its forks compoſed of ſtraight lines, and blunt ends.

FOURCHER, or Fourchir, Fr. an ancient law term, ſignifying a putting off, prolonging, or delaying an action.

As by ſtammering we draw out our ſpeech, not delivering that we have to ſay in ordinary time; ſo by fourching we prolong a ſuit that might be ended in a ſhorter ſpace.

In ſtat. Weſtm. I. cap. 42. we have theſe words: "Coparceners and joint-tenants ſhall be no more fourch, but only ſhall have one eſſoin," &c. And anno 6 Edw. I. cap. 10. it is uſed in the ſame ſenſe: "The defendants ſhall be put to anſwer without fourching," &c. In the Latin it is called *furcare*, and is uſed where a man and his wife do eſſoin ſeverally. "Caveat vir & mulier implacicati, quod ſemper in eſſonio alterius alter compareat, quamdiu furcare poſſint; & cum ultra non poſſint, concurrant coram eſſonio in ſuis locis: alter autem earum tantum unam eſſonium de malo lecti habere poteſt." Hengham Mag. cap. 9.

FOURCHES, in *Geography*, a chain of mountains in Switzerland, at the eaſtern extremity of the Valais, in which the Rhone riſes.

FOURCHETTE. *Fer de* Fourchette. See Fer.

FOURDAN-HOTUN, in *Geography*, a town of Corea, 653 miles E.N.E. of Peking. N. lat. 42° 51′. E. long. 131° 20′.

FOURMILLIER, in *Zoology*, the name given by Buffon to the *myrmecophaga didactyla* of Linnæus, or the little ant-eater; or leſſer yellowiſh *tamandua*; or the white American *coati*. See Myrmecophaga.

FOURMONT, Stephen, in *Biography*, diſtinguiſhed for his knowledge of languages, was born, 1683, in the neighbourhood of Paris. He had the misfortune to be early deprived of his parents, but his uncle placed him at the Mazarin college in Paris, where he quickly acquired a thorough knowledge of the Greek and Latin tongues. While a ſtudent he publiſhed "The roots of the Latin language put into French verſe," which was not only well received by the public, but immediately adopted as a ſchool book in various places of education. In connection with theological and philoſophical ſubjects, he began the ſtudy of the oriental languages. In the college of the Trente-ſois, he formed, in conjunction with the abbé Sevin, a ſociety of young eccleſiaſtics, ardent in literary purſuits, to read privately together the Greek and Latin poets, for which the leaders were expelled. Fourmont removed to the college of Montaigu, where he had the felicity of occupying the ſame apartment in which Eraſmus once lived, a circumſtance which increaſed his ardour for ſtudy. He gave a tranſlation of Aben Ezra's Commentary on Eccleſiaſtes, which increaſed his reputation as an orientaliſt. He was, after this, admitted an advocate, but never practiſed in that profeſſion. He was invited to Spain by the count de Toledo, who procured for him a penſion from the Spaniſh court, though he could not prevail upon Fourmont to leave his country. In 1715 he was appointed Arabic profeſſor in the royal college, and an aſſociate in the academy of inſcriptions and belles lettres; he gave public lectures in the Hebrew language, and put the Hebrew, Syriac, and Arabic roots into French verſe. He beſtowed much labour in attaining a knowledge of the Chineſe language; and engaged in the diſpute concerning Homer and the ancients which then divided the French literati. He was regarded by foreigners as well as by his own countrymen as an oracle in oriental learning, and was elected a member of the London and Berlin royal ſocieties. He died in the year 1745, leaving behind him many works that teſtify to his talents, his induſtry and learning; among theſe are "Reflexions critiques ſur les Hiſtoires des anciens Peuples juſqu'au Tems de Cyrus," in two vols. 4to. "A Chineſe grammar in Latin," folio. Moreri.

FOURNELS, in *Geography*, a town of France, in the department of Lozére, and chief place of a canton in the diſtrict of Marvejols. The place contains 571, and the canton 5932 inhabitants, in a territory of 197½ kiliometres, and 11 communes.

FOURNIER, Peter Simon, in *Biography*, an eminent engraver and letter founder, born at Paris in 1712, excelled in the practice of the typographical art, and illuſtrated it by his writings. He wrote ſeveral treatiſes on the origin and progreſs of his favourite art, which were collected in one volume 8vo. divided into three portions, of which the laſt contained a curious hiſtory of engravers in wood; but his moſt conſiderable production is entitled "Manuel Typo-

Typographique," in two vols. 8vo, deſigned as well for general readers as for the inſtruction of artiſts. He died in 1768; he was a man of great piety, fond of retirement, and extremely induſtrious.

FOURNIS, in *Geography*, a town of the iſland of Samos; two miles N.E. of Carlovaſſi.

FOURNO, a town of Aſiatic Turkey, in Caramania; 104 miles W.S.W. of Satalia.

FOURS, a town of France, in the department of the Niévre, and chief place of a canton in the diſtrict of Nevers. The place contains 80[illegible], and the canton 8222 inhabitants, on a territory of 382½ kiliometres, and in 13 communes.

FOURTEENTH, in *Muſic*, is the replicate or octave of the ſeventh; the major fourteenth has a ratio of $\frac{4}{15} = 1167\,\Sigma + 23\,f + 101\,m$; the greater minor fourteenth of ſome is $= \frac{5}{18} = 1131\,\Sigma + 22\,f + 98\,m$, and the leaſt minor fourteenth $= \frac{9}{32} = 1120\,\Sigma + 22\,f + 97\,m$.

FOURTH, one of the harmonic intervals or concords.

The fourth is the fourth in order of the concords. It conſiſts in the mixture of two ſounds, which are in the ratio of 4 to 3; *i. e.* of ſounds produced by chords, whoſe length are to each other as 4 : 3.

It is called fourth, becauſe containing four terms, or ſounds, between its extremes, and three degrees; or, as being the fourth in the order of the natural ſcale, from the fundamental.

Some modern muſicians have doubted whether the fourth ſhould be received among the number of concords, or not. The ancients expreſsly admitted it as ſuch, and Andreas Papius wrote a treatiſe againſt thoſe moderns who reject it. Merſen. Harm. lib. iv. prop. 8. Wallis, Append. Ptolem. Harm. p. 182. Indeed the ancients always regarded it as a concord of the moſt perfect kind. Its terms were the boundaries of all the tetrachordal ſyſtems; and though ranked as a diſcord by ſeveral moderns in counterpoint, it is ſtill a mathematical conſonance in the diviſion of the monochord; and even in counterpoint, as an inverſion of the fifth $\begin{matrix} C \\ G \end{matrix}$; nor can a common chord in triad be played in its firſt ſtage without a fourth in its compoſition $\begin{matrix} C \\ G \\ E \end{matrix}$. When accompanied by the fifth it is certainly a diſcord, and ſo is the third accompanied by the fourth, the fifth by the ſixth, &c. Dr. Pepuſch and Padre Martini claſs the fourth among perfect concords, and ſo do all theoriſts who have dipt into the muſic of the ancients, or mathematics.

N. B. Examples of the uſe of the fourth, in three and four parts, will be given in notation upon one of the muſic plates.

This is the interval which the ancients called diateſſaron or tetrachord: it is the complement of the fifth, and partakes much of its ſweetneſs of harmony; it conſiſts of five of the half-notes of keyed inſtruments which have 12 ſounds in the octave. It is uſually marked fourth in the works of thoſe who treat of muſical intervals, and it is the largeſt of the three concordant elements: its ratio is $\frac{3}{4} = \frac{3}{2^2}$, and in Mr. Farey's new notation is expreſſed by $254\,\Sigma + 5\,f + 22\,m$: its common logarithm is .8750612,6339, and its binary or Euler's logarithm .415038 (wherein the octave = 1); it is = 23.158110 major commas: it is alſo the ſum of a major, a minor, and a major ſemi-tone, is equal to two tones and a limma, to a minor third and minor tone, a major third and a major ſemi-tone, to a major tone, two limmas, and an apotome, and is a medius ſemi-tone leſs than the tritone. Beſides the above, ſeveral other intervals bear the names of fourth, as

FOURTH, *Flat*, the diminiſhed fourth of Tartini, or dieſis-exceſſive major third; it is leſs than a true fourth by the minor ſemi-tone, and conſiſts of four half-notes; its ratio is $\frac{25}{32}$ $= 218\,\Sigma + 4\,f + 19\,m = \frac{5^2}{2^5}$; its common logarithm is .8927900,3035, and its binary log. = .356143; it contains 19.87198 major commas, and conſiſts of a major third and an enharmonic dieſis, a minor third and a major ſemitone, a major tone and two major ſemi-tones; it is the exceſs of a major third over a minor third and minor fourth, and of an octave over two major thirds; by either of which laſt it may be tuned on an organ.

FOURTH, *Sharp*, the ſuperfluous or greater fourth of ſome, or deficient tritone, is greater than a true fourth by the minor ſemitone, and conſiſts of ſix half-notes; its ratio is $\frac{18}{25} \frac{= 2 \cdot 3^2}{5^2} = 290\,\Sigma + 6\,f + 25\,m$, its common logarithm is .8573324,9643, and its binary log. = .473932; it contains 24.44423 major commas, and conſiſts of a major and two minor tones; it is the difference between three major tones and two major commas, of a tritone and major comma, of a minor third and the ſum of a major third and minor fourth, and of a minor third and major ſixth, whence it may be tuned.

FOURTH, *Greateſt Sharp*, or redundant ſharp fourth, the tritone, falſe fourth, or tritonus of ſome, exceeds a true fourth by the medius ſemi-tone; its ratio is $\frac{32}{45} = \frac{2^5}{3^2 5} = 301\,\Sigma + 6\,f + 26\,m$: its common logarithm is .8519374,6454, and its binary log. .491851; it is 27.44423 major commas: it is equal to two major and one minor tones, to a major third and major tone, to the difference between a fifth and a major ſemi-tone, or three tones and a major comma; it is alſo the difference between a fourth, and two major and one minor third, or between a minor fourth and a fifth and major third, whence it may be tuned.

FOURTH, *Greateſt Sharp*, or double redundant ſharp fourth, the tritonus of the Greek ſcale, or ancient, or redundant, or ſuperfluous tritone of ſome, is larger than a true fourth by the apotome; its ratio is $\frac{512}{729} = \frac{2^9}{3^6} = 312\,\Sigma + 6\,f + 27\,m$; its common logarithm is .8465424,3266, and its binary log. 509772: it is 28.44423 major commas, and conſiſts of three major tones, or of three apotomes and three limmas: it is the difference between a fifth and a limma; between ſix fifths and three octaves, or between three fifths and three fourths, whence it can be tuned.

FOURTH, *Leſſer Flat*, or deficient flat fourth, is leſs than a true fourth by the medius ſemi-tone; its ratio is $\frac{405}{512} = \frac{3^4 5}{2^9}$ $= 207\,\Sigma + 4\,f + 18\,m$: its common logarithm is .8981850,6224, and its binary log. .338224: it is 18.87198 major commas: it is equal to a minor tone and two major ſemi-tones, to a minor third and a limma, to a major third and a minor comma; to a major tone, a major ſemi-tone, and a limma: it is alſo the difference between three 4ths and

and two major and one minor thirds, whence it may be tuned.

Fourth, *Leaſt Flat*, or double deficient flat fourth, is an apotome leſs than a true fourth, its ratio is $\frac{6561}{8192} = \frac{3^8}{2^{13}}$ $= 196\,\Sigma + 4f + 17m$; its common logarithm is .9035800,9412, and its binary log. = .320303; it is 17.87198 major commas; it is equal to a major tone and two limmas, to an apotome and three limmas; it is the difference between a major third and a ſchiſma, alſo between five octaves and eight fifths, or five fourths and three fifths, whence it may be tuned.

Fourth, *Comma-deficient*, the deficient fourth, or the leſſer fourth of Holder, is a comma leſs than a true fourth, as its name imports; its ratio is $\frac{243}{320} = \frac{3^5}{2^7 5} = 243\,\Sigma + 5f + 21m$; its common logarithm is .8804562.9528, and its binary log. = .397117; it is 22.15811 major commas, and conſiſts of two minor tones and a major ſemitone; of a major third and a limma; and is the difference between three fourths and two minor and one major thirds, whence it can be tuned.

Fourth, *Comma-redundant*, the redundant fourth, the greater fourth of Holder, and the ſuperfluous fourth of Galileo, exceeds a true fourth by the major comma; its ratio is $\frac{20}{27} = \frac{2^2 5}{3^3} = 265\,\Sigma + 5f + 23m$; its common logarithm is .8690662.3150, and its binary log. = .432958: it is 24.15811 major commas, and is equal to two major tones, and a major ſemitone, to a minor third and a major tone; it is the difference between two minor and one major thirds and a fourth, alſo between two fifths and a major ſixth, whence it may be tuned.

Fourth, *Diaſchiſma-exceſſive*, exceeds a true fourth by the diaſchiſma, being the reſulting fourth, or that between the *bearing notes*, when eleven ſucceſſive perfect fourths (or 11 fifths) are tuned in an octave: its ratio is $\frac{131072}{177147} = \frac{2^{17}}{3^{11}} = 266\,\Sigma + 5f + 23m$; its common logarithm is .8691761,2437, and its binary log. = .434583; it is 24.24895 major commas, is equal to two major tones and an apotome, to three apotomes and two limmas: it is the difference between a fifth and two limmas, between 11 fifths and ſix octaves, between five octaves and 11 fourths, or between five fifths and ſix fourths; whence it may be tuned.

Fourth, *Extreme diminiſhed*, the enharmonic leſſer third of ſome, is two minor ſemitones ſmaller than a true fourth, and an enharmonic dieſis greater than a minor third; its ratio is $\frac{625}{768} = \frac{5^4}{2^8 3} = 182\,\Sigma + 3f + 16m$: its common logarithm is .9105187,9731, and its binary logarithm .297249; it is 16.58587 major commas, and is equal to three major ſemitones and a major comma, to a major and a minor tone and an enharmonic dieſis: it is the difference between a minor fourth with two major thirds, and two minor thirds, or between a major twelfth and four major thirds, and hence it may be tuned on an organ.

Fourth *Point, Arches of the.* See Arch.

Fourth *Rate.* See Rate.

FOUSSERAT, in *Geography*, a town of France, in the department of the Upper Garonne, and chief place of a canton in the diſtrict of Murat; 29 miles S. W. of Toulouſe. The place contains 2,100. and the canton 7,857 inhabitants, on a territory of 187½ kiliometres, in 18 communes.

FOU-TCHEOU, a city of China, of the firſt rank, in the province of Fo-kien, and one of the moſt conſiderable cities in the province; diſtinguiſhed by the beauty of its ſituation, the trade it carries on, the number of its learned men, and the convenience of its rivers and port; and particularly by the magnificence of its principal bridge, which has more than 100 arches, conſtructed of white ſtone, and ornamented throughout with a double baluſtrade. This city is the reſidence of a viceroy, and has under its juriſdiction nine cities of the third claſs; 870 miles S. of Peking. N. lat. 26° 4′. E. long. 119° 4′.

Fou-tcheou, or *Vou-tcheou*, a city of China, of the firſt rank, in the province of Kiang-ſi, and formerly one of the moſt beautiful cities in China; but ſince the invaſion of the Tartars it has been a heap of ruins, conveying ſtill ſome idea of its ancient magnificence. The air is pure, the people are active and induſtrious, and the adjacent fields well cultivated. Its diſtrict is about 25 leagues in extent; and belonging to it are ſix cities of the third claſs.

FOU-TCHING-Y, a town of China, in the province of Kiang-nan; 17 miles N. E. of Liu-tcheou.

FOU-TCHUEN, a town of China, in the province of Chan-ſi; 35 miles E. N. E. of Ping-lo.

FOU-TSING, a town of China, of the third claſs, in the province of Fo-kien; 17 miles S. S. E. of Fou-tcheou.

FOUX, Cape, a cape on the N. W. coaſt of the iſland of Hiſpaniola. N. lat. 19° 46′. W. long. 74° 14′.

FOU-YANG, a town of China, of the third rank, in the province of Tche-kiang; 31 miles N. N. E. of Yen-tcheou.

FOUYU, a town of the kingdom of Corea; 16 miles N. of Hetſin.

FOWEY, or Fawey, a borough, market, and ſea-port town, in the hundred of Poweter, and county of Cornwall, is ſituated on the weſtern banks of the river Fawey, which here expanding its waters into a ſpacious eſtuary, forms a ſecure harbour, capable of receiving veſſels of a thouſand tons burthen at all ſtates of tide. This is a place of conſiderable antiquity, and made a diſtinguiſhed figure in a maritime and commercial view at ſeveral periods of our hiſtory. Leland informs us, that, ſubſequent to the conqueſt, it belonged to one Caridinham, a perſon celebrated in his day, who beſtowed it on a priory, ſaid to have been founded by him, near Tywardreth, at which time it was a ſmall fiſhing town. It owed its proſperity originally to the wars between the Engliſh and French; afterwards to an extenſive piratical ſyſtem; and at length flouriſhed by the more honourable means of commerce. This place was conſpicuous in the reigns of king Edward the Firſt and Third. In the time of the latter the veſſels of this port, ſailing by Rye and Winchelſea, and refuſing the demanded curteſy to thoſe havens, engaged the armed veſſels ſent to enforce it, which having defeated, the place in future, as a memorial of this event, quartered the arms of thoſe towns with its own armorial inſignia. In the reign of Edward the Fourth, after a peace had been concluded between this country and France, "the *gallants* of Fowey," as they were then termed, ſtill kept their ſhips in a warlike condition, and, in deſpite of the royal mandate to the contrary, carried on hoſtilities againſt the French; for which offence the veſſels belonging to this port were ſeized, and their commanders ſent priſoners to London. This induced the inhabitants to turn their attention from martial to commercial ſpeculations. In return for its devaſtations on the coaſt of France, Fowey received frequent hoſtile viſits from the French. For its defence in the time of Henry the Fourth, two ſquare baſtion forts

forts were erected with port-holes for mounting of cannon, the remains of which ſtand on each ſide the entrance to the harbour. As an additional ſecurity alſo, a large chain extended from fort to fort. Sir Thomas Treffry, in the time of Henry the Sixth, embattled and fortified his houſe, and erected a ſtrong additional tower, and thus converted it into a formidable caſtellated manſion. This, called *place*, though in a dilapidated ſtate, is worthy of notice from its antiquity, ſtyle of architecture, and ornamental ſculpture. During the civil wars this and the adjacent towns were occupied by the parliamentarians, under the command of the earl of Eſſex, where he was ſo hard preſſed, and ſurrounded by the king's troops, as to be driven to the diſgraceful expedient of abandoning the army to its fate, while he, the lord Roberts, and a few other officers made their eſcape, by embarking in a ſmall veſſel at Fowey, which conveyed them to Plymouth.

The houſes of the preſent town are in general conſtructed of ſtone, and extend for about a mile along the ſide of the river; but the ſtreets are ſo inconveniently narrow and irregular, that ſcarcely carriages of any deſcription can paſs through them. The church is a handſome edifice with a tower at the weſt end, decorated with many carved ornaments, and ſtrengthened by buttreſſes at the angles, terminating in purfled pinnacles. The roof is embelliſhed with angels carved in wood, ſuſtaining armorial ſhields, and various other devices; and ſome of the pews are ornamented in a ſimilar manner.

The market houſe is large and ſpacious, over which a neat town hall was erected a few years ago, at the expence of Philip Raſhleigh, and lord viſcount Valletort, at that time the parliamentary repreſentatives of the borough. The charitable eſtabliſhments are two free ſchools, an almſhouſe for eight decayed widows, and an excellent poor-houſe. Fowey is governed by a corporation, conſiſting of a mayor, eight aldermen, a recorder, and two aſſiſtants; of which the mayor and aldermen are juſtices of the peace. It is a feudal tenure, held under the prince of Wales as part of his duchy of Cornwall, and firſt ſent two members to parliament, the fourteenth year of Edward the Third, but the following year the privilege was diſcontinued, and the franchiſe not reſtored till the thirteenth of Elizabeth. The right of election, twice conteſted in one ſeſſions, appears to reſide in the prince's tenants, admitted to fealty and homage, and in all the inhabitants who pay ſcot and lot. Here are a well ſupplied weekly market on Saturdays, and three annual fairs. According to the returns made under the population act in 1801, the number of houſes was 213, containing 1155 inhabitants.

Fowey, by a late traveller, has properly been denominated "a colony of fiſhermen;" for moſt perſons here are either directly or remotely connected with the *pilchard* fiſhery, in which concern many veſſels belonging to the town are uſually employed. At the ſeaſon when the annual ſhoal of pilchards is expected, a number of watchmen, called *huers*, are ſtationed on the neighbouring rocks, to obſerve and give notice to the fiſhermen of the courſe and direction taken by the fiſh: ſmall ſail-boats are alſo diſpoſed of along the coaſt for the ſame purpoſe. It is eſtimated, that, on an average every ſeaſon, upwards of 28,000 hogſheads of fiſh are caught and brought into this port. The refuſe of the ſalt and broken fiſh are generally ſold for agricultural purpoſes, at about half a guinea per cart load. During other parts of the year, numerous trawl-boats are occupied in taking divers kinds of white fiſh, and ſome of the inhabitants find employ in the tin mines of the vicinity. The harbour is now defended by two ſmall batteries, recently erected, and St. Catherine's fort, built by the townſmen in the reign of Henry the Eighth, which is ſituated on the ſummit of a magnificent pile of rocks, that bound one ſide of the river. Theſe rocks are compoſed of a hard blueiſh ſlate, containing veins of a ſubſtance, which, from the greaſineſs to the touch, is denominated by mineralogiſts *fat quartz*. Thoſe on the Polruan ſide are extremely rude and bold, and, with the ruins of a chapel, form highly pictureſque ſcenery. See Leland's Itinerary. Polwhele's Hiſtory of Cornwall. Beauties of England and Wales.

FOWL, in a general ſenſe, is of equal import with bird.

Fowl is, in a more peculiar manner, underſtood of poultry, or the larger ſort of birds, both domeſtic and wild, either bred up, or hunted, for the table.

Such as turkies, geeſe, cocks, hens, and ducks, both wild and tame, pheaſants, partridges, pigeons, ſnipes, &c. See Poultry.

Though birds of this ſort can only afford profit under particular circumſtances, and in ſituations that are adapted to them, the farm yard cannot be ſaid to be properly ſtocked unleſs they are found in it. They are beſides, in many caſes, extremely convenient in affording eggs and feathers, as well as in the young brood. They are generally the moſt profitable on farms of the arable kind, where grain muſt be unavoidably ſcattered, and near large market towns, where they can be readily diſpoſed of at good prices. In chooſing ſtock of this ſort, young hens are to be preferred where eggs are wanted, and old ones, where chickens are the chief objects of the farmer. Some ſorts of hens are much better layers and breeders than others, which ſhould always, of courſe, be choſen. They may be ſet from two years old to five, with moſt advantage, and from the beginning of February to near Michaelmas. They ſit about three weeks in general, and ſhould be well ſupplied with meat, water, and ſand, during the time, that they may not leave their eggs too long, in ſeeking them. One male bird is ſufficient for ten or twelve females.

Breeding and laying fowls ſhould be kept well, but not by any means ſo as to be fat. They may be fed with any ſort of grain or ſeeds; but where their food is buck-wheat, hemp, canary, or other ſeeds of a ſimilar kind, they are ſaid to lay the beſt. Animal ſubſtances are likewiſe aſſerted to make them lay earlier than uſual.

In fattening fowls, the common food is moſtly ſome ſort of grain, or barley meal moiſtened with milk; but ſome prefer wheat flour mixed with ſteamed potatoes, and others buck-wheat ground into flour and made into a ſort of paſte with milk. They require to be carefully and regularly fed during the time they are fattening.

It is neceſſary, in order to derive the greateſt poſſible profit from fowls, to have a proper houſe, and ſmall incloſure ſet apart for their reception, contiguous to the farm yard, into which they ſhould conſtantly have free acceſs. They ſhould in addition be regularly fed once or twice in the day in the houſe, and kept ſufficiently warm during the ſevere weather in the winter ſeaſon.

Turkeys require care at the time of their hatching, and while the brood is young, but are afterwards equally hardy with the common fowl. See Turkey and Poultry.

Geeſe and ducks are fowls of the water kind, which require but little care where they have large ponds or other waters to feed and ſwim upon. They will however require to be fed in the ſevere winter months with ſome ſort of grain, or other kinds of food. Geeſe and ducks that are ſome years old are the beſt for breeding from, and one male bird is ſufficient for ſeveral females.

The

The lighteſt coloured geeſe are the beſt, and thoſe that begin to lay the ſooneſt; as they have a chance of hatching twice in one year. They begin to lay in the ſpring, and lay twelve or ſixteen eggs. Green geeſe are begun to be fattened at a month old, and will be fattened in a month more. Old geeſe are chiefly fattened at ſix months old, in or after the harveſt. A wild gooſe, if red-footed and hairy, is old; but if white-footed, and not hairy, ſhe is young. See Goose and Poultry.

When the eggs are ſet under a hen, or other fowl, it is adviſeable to mark the upper ſides thereof: and when ſhe goes to feed, to note whether ſhe minds to turn them upſide down or not; if ſhe neglect that office it may be done for her.

The *Sea-fowls*, which come on ſhore in immenſe numbers to rooſt in the north iſlands of Scotland, ſet their watches and centinels at diſtant poſts, to give them notice of any danger; on the leaſt alarm from theſe, the whole body riſes, but without ſuch notice they are not to be alarmed by almoſt any thing. The people of the country know this; and when they go out to take them, they employ all their art to take the centinels without noiſe; this they ſometimes ſucceed in, and when they do, they often afterwards catch three hundred of the others, or more, in one night. Phil. Tranſ. N° 233.

The laying of theſe ſea-birds is leſs certain as to time than might be imagined. They can occaſionally defer it; and as they uſually lay in a rainy ſeaſon, if the rain does not come on at the uſual time, they will defer it ſome weeks; and if the April moon goes far in May, that alſo has been obſerved to hinder them from laying ten or twelve days longer than ordinary. See Bird.

Water-fowl may be taken in great abundance by nets properly managed. The net for this purpoſe ſhould be always made of the ſmalleſt and ſtrongeſt packthread that can be got. The meſhes may be large, but the nets ſhould be lined on both ſides with other ſmaller nets, every meſh of which is to be about an inch and a half ſquare each way, that as the fowl ſtrike either through them or againſt them, the ſmaller may paſs through the great meſhes, and ſo ſtraighten and entangle the fowl.

Theſe nets are to be pitched for every evening flight of fowl, about an hour before ſun-ſet, ſtaking them on each ſide of the river, about half a foot within the water, the lower ſide of the net being ſo plummed, that it may ſink ſo far and no farther; place the upper ſide of the net ſlantwiſe, ſhoaling againſt the water, but not touching it by near two feet; and let the ſtrings, which ſupport this upper ſide of the net, be faſtened to ſmall yielding ſticks ſet in the bank; theſe, as the fowl ſtrikes, will give the net liberty to play, and to entangle them. Several of theſe nets ſhould be placed at once over different parts of the river, at about twelve ſcore fathom diſtance one from another: and if any fowl come that way, the ſportſman will have a ſhare of them. It is a good method, when the nets are ſet, to go to places ſufficiently diſtant from them with a gun, to frighten them toward the places where the nets are; and wherever any of the fowl are ſtarted from, it may not be amiſs to plant ſome nets alſo there, to take them as they return. The nets are to be left thus placed all night, and in the morning the ſportſman is to go and ſee what is caught; he ſhould viſit the river firſt, and take up what are caught there, and frightening the reſt away to the other places where his nets are, he is next to viſit them, and take what are there ſecured.

The Ceyloneſe have great plenty of water-fowl wild on their iſland, and have a very remarkable way of catching them, which is this: the fowler enters a lake or other water which has a good bottom, and is not very deep; he puts an earthen pot upon his head, in which there are bored holes, through which he can ſee; he keeps himſelf ſo bent down in the water, that only the pot is above the ſurface; in this manner he enters the place where the wild fowl are in cluſters, and they think it is only ſome floating block. He then takes ſome one by the legs, and gently draws it under water, and wrings its neck till he has killed it; then putting it into his bag, which is faſtened about his middle, he takes hold of another in the ſame manner, and ſo on, till he has got as many as he can carry off, and then he goes back in the ſame manner in which he came, not diſturbing the reſt of the birds, who never miſs their companions, but only ſuppoſe that they dive down for their diverſion, when the fowler pulls them under. In places where this has been practiſed ſo long or ſo careleſsly, that the birds are ſhy, the fowler uſes a gun; but this he does in the following manner: he makes a ſcreen of about five feet high, and three feet wide, which he carries in one hand ſtraight between himſelf and his game, and in the other hand his gun. The birds are not alarmed at what appears only a buſh; for this ſcreen is always covered with branches of trees freſh cut down, and full of leaves, ſo that the ſportſman behind advances as near as he pleaſes, and then putting the gun through ſome crevice of the ſcreen, he fires. See Decoy. See alſo Bird-*Catching*.

Fowl *Dung*, the dung of all ſorts of domeſtic birds, which is ſaid to be excellent as a top-dreſſing, when ſown over young corn crops by the hand. See Top-*dreſſing*.

Fowl *Manure*, that ſort which is afforded by fowls, See Manure.

Fowl, *Wild, driving of*. See Driving.

FOWLER, Edward, in *Biography*, was born in the year 1632, at Weſterleigh, in Glouceſterſhire, of which place his father was miniſter, till he was ejected by the act of uniformity. Having been well grounded in the elementary parts of learning, he obtained the appointment of one of the clerks to Corpus Chriſti college, in the univerſity of Oxford. In 1653 he was choſen one of the chaplains of the inſtitution, and ſoon after took his degree of bachelor of arts. At Trinity college, Cambridge, he took the degree of maſter of arts, and was incorporated in the ſame degree at Oxford, in the year 1656. He was preſented about this period with the rectory of Northill, in Bedfordſhire, but as he had been educated in Preſbyterian principles, he ſcrupled, at firſt, to comply with the terms of conformity, eſtabliſhed at the reſtoration of Charles II.; his views being, however, changed, he was admitted a clergyman of the church of England, to which he ſteadily adhered to the end of his life. In the year 1673 he was introduced by archbiſhop Sheldon to the living of All-hallows, Bread-ſtreet, London: and ſoon after he was preſented with a prebend in the cathedral church of Glouceſter; and with the vicarage of St. Giles's, Cripplegate. In 1681 he accumulated the degrees of bachelor and doctor of divinity in the univerſity of Oxford. Dr. Fowler poſſeſſed a mind much too liberal for the times in which he lived. He was proſecuted and ſuſpended by the inſtruments of James II.'s tyranny, under pretence of having tranſgreſſed the canons of the church. He was not to be intimidated by the infliction of illegal puniſhments: he ſtill reſiſted the unconſtitutional attempts of king James to extend the regal prerogative by aſſuming a power to diſpenſe with the exiſting laws; and was the ſecond perſon who, in 1688, ſigned a reſolution entered into by the London clergy, not to read the king's new declaration for liberty of conſcience. This reſolution

was

was taken in oppoſition to the king's aſſumption of a diſpenſing power, which tended to the ſubverſion of the conſtitution, and to inveſt him with arbitrary authority. The clergy in this cauſe were ſupported by all the conſiſtent friends of liberty among the diſſenters, and in the eſtabliſhment. When the new government was ſettled, Dr. Fowler's learning and zeal were not forgotten: he was in 1691 nominated to the ſee of Glouceſter, in which ſituation he remained, diſcharging with exemplary aſſiduity the duties of his biſhopric until he was diſabled by his growing infirmities. He died at Chelſea, near London, in 1714, in the eighty-ſecond year of his age. He had been a great writer, but his works being chiefly of the controverſial kind, it would be of little uſe to enumerate them here, ſince almoſt all the ſubjects then in diſpute have long ſince been laid at reſt. One of the principal of the biſhop's works, and which reflects much credit on his underſtanding and memory, was entitled, "The Deſign of Chriſtianity, or a plain demonſtration and improvement of this propoſition, *viz.* that the enduing men with inward, real righteouſneſs, or true holineſs, was the ultimate end of our Saviour's coming into the world, and is the great intendment of his bleſſed goſpel." Biog. Brit.

Fowler, Thomas, was born at York on the 22d of January, 1736, and, after having gone through a courſe of claſſical and medical education, he engaged in the practice of pharmacy, in his native city, in the year 1760. In 1774, however, he relinquiſhed this branch of practice, in order to apply himſelf more cloſely to the ſtudy of medical ſcience; and for this purpoſe he went to Edinburgh, where he graduated in 1778. He then ſettled at Stafford, and was ſoon after elected phyſician to the infirmary at that place, where he practiſed with conſiderable reputation and ſucceſs until the year 1791, when he returned to his native city. Here he met with the moſt flattering encouragement in the exerciſe of his profeſſion: but his ardent attention to his profeſſional duties and ſtudies was conſiderably interrupted, in July 1793, by an attack of a painful, anomalous diſeaſe of the cheſt, which he deſcribed as "fits of ſpaſmodic aſthma, attended with moſt of the painful ſymptoms of the angina pectoris." After conſulting many eminent phyſicians, and trying a variety of medicines, with partial and tranſient relief, for two years, he was agreeably ſurpriſed by a ſpontaneous and gradual decline of the ſymptoms, and was at length totally free from them. Notwithſtanding the check to his exertions which he received from this complaint, his profeſſional emoluments and reputation continued to increaſe; and in 1796 he was appointed, without ſolicitation, and even without his knowledge, phyſician to the lunatic aſylum, near York, called the "Retreat," eſtabliſhed by the ſociety of quakers, for the relief of the inſane members of their community. He was a member of the medical ſocieties of Edinburgh, of the medical ſociety of London, and of the Briſtol medical ſociety; in the latter of which he was propoſed by a gentleman to whom he was perſonally unknown, (Dr. Fox,) and who informed him of his election in an epiſtle highly flattering to his literary and profeſſional attainments. Dr. Fowler continued his uſeful career, active in every duty that benevolence could dictate, or friendſhip demand, and, in the exerciſe of his profeſſion, an example of generoſity, unwearied diligence and humanity, until the year 1801, when he died, on July 22d, while upon a viſit to ſome friends in London.

He was attached to the ſtudy of medicine with almoſt enthuſiaſtic partiality, and ſtudiouſly cultivated as a ſcience, what he induſtriouſly practiſed as a duty. He exemplified the method recommended by lord Bacon for the improvement of medicine, perhaps more than any of his predeceſſors or contemporaries; and ſome idea of his indefatigable labours may be conceived, when we mention, that he left in manuſcript the hiſtory of more than ſix thouſand caſes, which fell under his own inſpection and treatment. From this ſtore of experimental knowledge he publiſhed ſeveral works. The firſt of theſe was entitled, "Medical Reports on the Effects of Tobacco," which was publiſhed in the year 1785; and in the year following his ſecond treatiſe appeared, under the title of "Medical Reports on the Effects of Arſenic." Theſe uſeful works tended, in a conſiderable degree, to remove the fears and prejudices of practitioners with regard to theſe violent, but, under proper regulation, important and moſt beneficial agents, and to inſtruct the profeſſion in the means of rendering them ſafe and manageable as remedies; and accordingly they are now, more eſpecially the latter, in daily and familiar uſe, and rank among the valuable articles of the materia medica. Even during the two years, in which his literary exertions were conſiderably impeded by the painful diſeaſe under which he laboured, he was actively employed, in the intervals of eaſe, in arranging from his notes materials for other works upon the ſame plan; and in 1795 he dedicated to the medical profeſſors of Edinburgh a volume of "Medical Reports on the acute and chronic Rheumatiſm." Had his uſeful life been prolonged, he would have purſued ſtill farther this plan of inductive experience, after the Baconian ſyſtem, and have contributed to the farther advancement of his favourite ſcience. He was, beſides, the author of ſeveral papers, printed in different volumes of the Medical Commentaries, and Annals of Medicine, edited by Drs. Duncan of Edinburgh. See Ann. of Med. for 1801.

FOWLING, the act or art of catching birds with nets, birdlime, decoys, and other devices; as alſo of breeding up the ſame.

Fowling is alſo uſed for the purſuing and taking of birds with hawks, falcons, and other birds of prey; more properly called falconry and hawking.

Fowling-*piece*, a portable fire-arm for the ſhooting of birds. Of fowling pieces, thoſe are reputed the beſt, which have the longeſt barrel, *viz.* from $5\frac{1}{2}$ feet to 6, with a moderate bore; though for different occaſions they ſhould be of different ſorts and ſizes: but in all it is eſſential the barrel be well poliſhed, and ſmooth within, and the bore of an uniform bigneſs, from one end to another; which may be proved by thruſting in a piece of wood, cut exactly to the bore of the muzzle, down to the touch-hole; for if this goes down without ſtoppage, you may conclude that the bore is good. The bridge-pan ſhould be a little above the touch-hole, and ought to have a notch to let down a little powder, which will prevent the piece from recoiling. The locks ſhould be accurately filed, and their ſprings be neither too ſtrong nor too weak. The hammer ought to be well hardened, and pliable, ſo as to go down to the pan with a quick motion.

The following obſervations on the manufacture and perfection of a fowling-piece are extracted from the "Pantologia." In forming the gun-barrel, the workmen begin by heating and hammering out a bar of iron into the form of a flat ruler, thinner at the end intended for the muzzle, and thicker at that for the breech; the length, breadth, and thickneſs of the whole plate being regulated by the intended length, diameter, and weight of the barrel. This oblong plate is then, by repeated heating and hammering, turned round a cylindrical rod of tempered iron, called a mandril, whoſe diameter is conſiderably leſs than the intended bore of the barrel. The edges of the plate are made to overlap each

other about half an inch, and are welded together by heating the tube in lengths of two or three inches at a time, and hammering it, with very briſk but moderate ſtrokes, upon an anvil which has a number of ſemi-circular furrows in it, adapted to the various ſize of the barrels. The heat required for welding is the bright white heat, which immediately precedes fuſion, and at which the particles of the metal unite and blend ſo intimately with each other, that, when properly managed, not a trace is left of their former ſeparation. Every time the barrel is withdrawn from the forge, the workman ſtrikes the end of it once or twice gently againſt the anvil in an horizontal direction: this operation, called by the Engliſh artiſts "jumping," and by the French "eſtoquer," ſerves to conſolidate the particles of the metal more perfectly, and to obliterate any appearance of a ſeam in the barrel. The mandril is then introduced into the bore or cavity; and the barrel, being placed in one of the furrows or moulds of the anvil, is hammered very briſkly by two perſons beſides the forger, who all the while keeps turning the barrel round in the mould, ſo that every point of the heated portion may come equally under the action of the hammers. Theſe heatings and hammerings are repeated until the whole of the barrel has undergone the ſame operation, and all its parts are rendered as perfectly continuous as if it had been bored out of a ſolid piece.

The imperfections to which a gun-barrel is liable in forging are of three kinds, *viz.* the chink, the crack, and the flaw. The chink is a ſolution of continuity, running lengthways of the barrel; the crack is a ſolution of continuity, more irregular in its form than the chink, and running in a tranſverſe direction, or acroſs the barrel; the flaw is a ſmall plate or ſcale, which adheres to the barrel by a narrow baſe, from which it ſpreads out as the head of a nail does from its ſhank; and, when ſeparated, leaves a pit or hollow in the metal. The chink and flaw are of much greater importance with regard to the ſoundneſs of the barrel than the crack, as the effort of the powder is exerted upon the circumference, and not upon the length of the barrel. The flaw is much more frequent than the chink. Theſe defects, within the barrel, are of a material diſadvantage, by affording a lodgement to moiſture and foulneſs that corrode the iron, and thus continually enlarge the excavation until the barrel burſts, or becomes dangerous to uſe.

The barrel, when forged, is either finiſhed in the common manner, or made to undergo the operation of twiſting, which is a proceſs employed in thoſe barrels that are intended to be of a ſuperior quality and price to others. This operation conſiſts in heating the barrel, in portions of a few inches at a time, to a high degree of red heat; when one end of it is ſcrewed into a vice, and into the other is introduced a ſquare piece of iron with a handle like an augre; and by means of theſe, the fibres of the heated portion are twiſted in a ſpiral direction, that is found to reſiſt the efforts of the powder much better than a longitudinal one.

It is a circumſtance of conſiderable importance with reſpect to the excellence of a barrel, that it ſhould be forged as nearly as poſſible to its weight when finiſhed, ſo that very little may be taken away in the boring and filing: for, as the outer ſurface, by having undergone the action of the hammer more immediately than any other part, is rendered the moſt compact and pure, we ſhould be careful to remove as little of it as poſſible. Such is alſo the caſe, though in a leſs degree, with regard to that portion of the middle of the barrel which is to be cut out by the boring inſtrument.

Piſtol-barrels are forged in one piece, and are cut aſunder at the muzzles after they have been bored; by which there is not only a ſaving of iron and of labour, but a certainty of the calibre being perfectly the ſame in both.

The next operation conſiſts in giving to the barrel its proper calibre; this is termed boring. The boring bit is a rod of iron, ſomewhat longer than the barrel; one end being made to fit the ſocket of the crank, and the other being furniſhed with a cylindrical plug of tempered ſteel, about 1½ inch in length, and having its ſurface cut in the manner of a perpetual ſcrew, the threads being flat, about ¼ of an inch in breadth, and running with very little obliquity. This form gives the bit a very ſtrong hold of the metal; and the threads, being ſharp at the edges, ſcoop out and remove every roughneſs and inequality from the inſide of the barrel, and render the cavity ſmooth and equal throughout. A number of bits, each a little larger than the preceding one, are afterwards ſucceſſively paſſed through the barrel in the ſame way, until it has acquired the intended calibre. The equality of the bore is of great moment; and it may be tried with tolerable accuracy, by means of a plug of lead, caſt on a rod of iron or wood; or even by a muſket-ball, filed ſo as to fit the bore exactly, and puſhed through the barrel by the ram-rod; care being taken not to uſe an iron ram-rod, or much force, leſt the ball be flattened, and an artificial difficulty created.

The gun-ſmiths afterwards poliſh the barrel; and it is then in a condition to receive its proper form and proportions externally, by means of the file. To do this with accuracy, four flat ſides or faces are firſt formed; then eight, then ſixteen, and ſo on, until it is made quite round; except the reinforced part, which, in moſt of the modern work, is left with eight ſides.

It is abſolutely neceſſary to the ſoundneſs of a barrel, that it ſhould be of an equal thickneſs on every ſide; or, in the language of the workmen, a barrel ought to be perfectly upright. To accompliſh this, the gun-ſmiths employ an inſtrument which they call a "compaſs," conſiſting of an iron rod bent ſo as to form two parallel branches, about an inch diſtant from each other. One of theſe branches is introduced into the barrel, and kept cloſely applied to the ſide by means of one or more ſprings with which it is furniſhed; the other branch deſcends parallel to this, on the outſide, and has ſeveral ſcrews paſſing through it with their points directed to the barrel. By ſcrewing theſe until their points touch the ſurface of the barrel, and then turning the inſtrument round within the bore, it is ſeen where the metal is too thick, and how much it muſt be reduced in order to render every part of the barrel perfectly equal throughout its circumference. To form the ſcrew in the breech-end of the barrel, the firſt tool employed is a plug of tempered ſteel, ſomewhat conical, and having upon its ſurface the threads of a male ſcrew. This tool, which is termed a "ſcrew-tap," being introduced into the barrel, is turned from left to right, and back again, until it has marked out the three or four firſt threads of the ſcrew; another leſs conical tap is then introduced; and when this has carried on the impreſſion of the ſcrew as far as it is intended to go, a third tap is employed, which is nearly cylindrical, and ſcarcely differs from the plug of the breech which is intended to fill the ſcrew thus formed in the barrel. The breech-plug has its ſcrew formed by means of a ſcrew-plate made of tempered ſteel, and has ſeveral female ſcrews correſponding with the taps employed to form that in the barrel. A plug of ſeven or eight threads is ſufficiently long; and the threads ought to be neat and ſharp, ſo as to fill completely the turns made in the barrel by the tap. The breech-plug is afterwards caſe-hardened, or, has its ſurface

converted into ſteel, by being covered over with ſhavings of horn, or parings of horſe-hoof, and kept red-hot in the fire for ſome time, after which it is plunged into water.

The laſt operation is that of colouring the barrel, previouſly to which it is poliſhed with fine emery and oil, until it preſents to the eye, through its whole length, and in whatever direction it is obſerved, a perfectly ſmooth, equal, ſplendid ſurface. Inſtead of blueing the barrels by expoſing them to a degree of heat, which produced an elegant blue tinge, which was formerly done, they are now browned, as it is termed. To do this, the barrel is rubbed over with aqua fortis, or ſpirits of ſalt, diluted with water, and laid by until a complete coat of ruſt is formed upon it; a little oil is then applied; and the ſurface, being rubbed dry, is poliſhed by means of a hard bruſh and bees' wax.

Barrels intended for a double-barrelled piece, after having been dreſſed to their proper thickneſs, which is generally leſs than for ſingle barrels, are filed flat on the ſides that are to join each other, ſo that they may fit cloſe together. Two correſponding notches are then made at the muzzle and breech of each barrel; and into theſe are fitted two ſmall pieces of iron, to hold them more ſtrongly together. The barrels being united by tinning the parts which touch, the ribs are fitted in, and made faſt by the ſame means. Theſe ribs are the triangular pieces of iron which are placed between the barrels, running on the upper and under ſides their whole length, and ſerving to hold them more firmly together. The under rib is a late improvement, and is found more effectually to prevent the barrels from warping. When the barrels are thus joined, they are poliſhed and coloured in the manner already deſcribed.

The twiſted barrels are deſervedly commended for their ſuperior elegance and ſtrength, as well as for the accuracy with which they throw their ball or ſhot. The iron employed in them is formed of old horſe-ſhoe nails, originally made from the ſofteſt and tougheſt iron, which is farther purified by the numerous heatings and hammerings by which it is reduced firſt into a bar, and then into nails. About 28 pounds of theſe ſtubs, purchaſed at about 10*s. per cwt.*, are required to make a ſingle barrel of the ordinary ſize. A hoop of iron, about an inch broad, and ſix or ſeven inches in diameter, is placed perpendicularly; and the ſtubs, previouſly waſhed, are neatly piled in it, with their heads outermoſt on each ſide, until the hoop is quite filled and wedged tight with them; the whole reſembling a rough circular cake of iron. This is put into the fire until it has acquired a white heat; when it is hammered, either by the ſtrength of the arm, or by the force of machinery, until it becomes one maſs of ſolid iron; the hoop is then removed, and the heatings and hammerings repeated, until the iron, by being thus wrought and kneaded, is freed from all impurity, and rendered very tough and cloſe in the grain: the workman then draws it out into pieces of about 24 inches in length, half an inch or more in breadth, and half an inch in thickneſs. Theſe pieces, however, are of different thickneſs, according to the propoſed thickneſs of the barrel, and that part of it which the piece was intended to form. One of theſe pieces, being heated red-hot for five or ſix inches, is turned like a cork-ſcrew, without any other tools beſides the anvil and hammer. The remaining portions are treated in the ſame manner, until the whole piece is turned into a ſpiral, forming a tube whoſe diameter correſponds with that of the intended barrel. Four of theſe are generally ſufficient to form a barrel of the ordinary length, which is from 32 to 38 inches, and the two which form the breech or reinforced part are conſiderably thicker than thoſe which conſtitute the fore-part, or muzzle of the barrel. The workman firſt welds one of theſe tubes to a part of an old barrel, which ſerves as a handle. He then proceeds to unite the turns of the ſpiral to each other, by heating the tube two or three inches at a time, to a bright white heat, and ſtriking the end of it ſeveral times againſt the anvil in a horizontal direction, and with conſiderable force; this is termed jumping by the barrel; and the heats given for this purpoſe are called jumping-heats. A mandril is then introduced into the cavity; and the heated portion is hammered ſlightly, to flatten the ridges or bars raiſed by the jumping at the place where the ſpirals are joined. As ſoon as one piece is jumped its whole length, another is welded to it, and treated in the ſame manner, until the four pieces are united; when the part of the old barrel, being no longer neceſſary, is cut off. The welding of the turns of the ſpiral is performed in the manner already deſcribed, and is repeated three times. The barrel is afterwards finiſhed in the ſame mode as the common one.

Stub iron is alſo wrought into plain barrels; which, as they require much leſs labour, are only half the price of the twiſted ones.

The "canons or rubans," or ribbon barrels of the French, very much reſemble the Engliſh twiſted barrels. The proceſs by which they are formed is much more operoſe than that above deſcribed, without poſſeſſing any ſuperior advantage.

It is obſerved, as the reſult of various experiments with barrels of 28, 30, 32, 34, 36, 38, and 40 inches in length, that the difference of 10 inches in the lengh of the barrel, which ſeems to be more than ſportſmen require, produces no ſenſible difference in the range of the piece; and, therefore, that every one may pleaſe himſelf in the length of his barrel, without detriment or advantage to the range. (See RANGE.) The circumſtance, it is ſaid, of a duck-gun killing at a greater diſtance than a fowling-piece, is not owing to its length, but to its greater weight and thickneſs, allowing the charge of powder to be doubled, trebled, or even quadrupled; which cannot be done in a fowling-piece, though ſtrongly reinforced. Duck-guns are generally bent a little upwards near the muzzle, which, as the gunſmiths ſay, makes them throw their ſhot further than if they were perfectly ſtraight. To obtain from a piece of the ordinary length the ſame effects as from a duck-gun, nothing more, perhaps, is neceſſary, than to have the barrel ſufficiently ſtrong to admit of the charge being doubled or trebled as required, and the whole piece heavy enough to render the recoil ſupportable. It is further obſerved, that an increaſe of the powder above the charge generally uſed, does not produce a proportional increaſe of range in the ball or ſhot: thus, a double charge of powder will not throw the ball or ſhot to twice the diſtance, nor a treble charge to three times the diſtance, of the ſingle charge. This is owing to the great reſiſtance given by the air to the motion of the ball or ſhot, which is proved to be four-fold if the velocity be doubled, and nine-fold when it is trebled by an increaſe of powder; for the reſiſtance of the air is not proportional to the velocity itſelf, but only to the ſquare of the velocity. (See GUNNERY and RESISTANCE.) So great is the change in opinion of late, with regard to the proper length of gun-barrels, that many gunſmiths will now tell us, that ſhort barrels carry farther than long ones; and the reaſon they give for it is, the greater friction of the ball or ſhot in paſſing through a long barrel, by which their velocity is retarded and their force diminiſhed. If the barrel is ſo long that the additional impulſe which the ball or ſhot is continually receiving in its paſſage

becomes leſs than the friction between them and the ſides of the calibre, then, indeed, the barrel, by being ſhortened, will ſhoot with greater force; but as the length of the barrel required to produce this effect is vaſtly greater than can ever be employed for any purpoſe, the objection does not hold. It ſeems clear, that a piece may be made ſo long, that it will not throw a ball with ſo great velocity as one that is conſiderably ſhorter; and the reaſon of this decreaſe of velocity may be, that in very long pieces the increaſe of the counter-preſſure of the external air in the cylinder, may greatly exceed the force of the powder, and that the elaſtic fluid generated by the exploſion of the powder is conſtantly eſcaping whilſt the ball paſſes along the cylinder, which it not only does at the touch-hole, but alſo between the ball and the ſides of the barrel; and hence may be inferred the neceſſity of touch-holes which do not prime of themſelves, and of wadding that ſtops the barrel hermetically. The following opinion is given by the ingenious writer of the article to which we have referred with regard to the length of barrel that is beſt calculated for general uſe. The barrels which are found to anſwer beſt for every purpoſe are from thirty-two to thirty-eight inches; and whether we conſult the appearance of the piece, its lightneſs, or the eaſe with which it is managed, we believe, (he ſays,) that a barrel not exceeding the one, or below the other, of theſe numbers, is the moſt eligible. We know that many of the gunſmiths pique themſelves on the proportion they give to the different parts of their fowling-pieces, and thence deduce a ſuperiority over their contemporaries in favour of their own. To us it appears that the beauty of thoſe proportions is more attended to than any good reaſon why they are made ſo rather than otherwiſe. For other particulars ſee PROVING *of Guns*, RANGE, RECOIL, and RIFLE.

In ſhooting, obſerve to do it with the wind, if poſſible, and rather ſide-ways, or behind the fowl, than full in their faces. Obſerve alſo to chuſe the moſt convenient ſhelter, as a hedge, bank, or tree. If you have not ſhelter enough, you muſt creep upon your hands and knees, or uſe a ſtalking-horſe. Let your dogs be under good command. See DOG, SETTING-*Dog*, and SPANIEL.

FOX, RICHARD, in *Biography*, a celebrated Engliſh ſtateſman and prelate, was deſcended from parents in mean circumſtances, and born at Ropeſley, near Grantham, in Lincolnſhire, about the end of the reign of Henry VI. Having paſſed through the introductory ſteps of learning, he was ſent to Magdalen college, Oxford, where he acquired diſtinguiſhed reputation by the progreſs he made in his ſtudies. The plague, then not unfrequent in England, broke out in Oxford, which forced Mr. Fox to finiſh his education at Pembroke Hall, Cambridge, and from thence he went to Paris to ſtudy canon law and theology. In this city he obtained the notice and friendſhip of Dr. Morton, biſhop of Ely, who had been driven from his native ſoil by the perſecutions of the infamous Richard III. It was by the means of this prelate that Fox, who had been created doctor, was introduced to Henry, earl of Richmond, who was at that time projecting a ſcheme to dethrone Richard. Dr. Fox entered into his views, was admitted into his moſt ſecret counſels, and undertook and accompliſhed that part of the plan which was entruſted to him. After Henry had gained the crown of England as the reſult of the victory of Boſworth-field, he appointed Dr. Fox one of his privy councillors, and, next to Dr. Morton, admitted him to the greateſt ſhare of his confidence and familiarity. Beſides other inſtances of preferment, he was nominated in 1486-7 biſhop of Exeter; appointed keeper of the privy ſeal; made principal ſecretary of ſtate, and maſter of St. Croſſe, near Wincheſter. From this time, notwithſtanding his high ſtation in the church, Dr. Fox was conſtantly engaged by his ſovereign, either in the management of public affairs at home, or on important foreign embaſſies. In 1491 he was tranſlated from Exeter to the biſhopric of Bath and Wells; whence he was afterwards removed to Durham in 1494. He was now ſent on an embaſſy to James IV. of Scotland to terminate ſome differences reſpecting the fiſheries of the river Eſk; but with all his ability and addreſs he was unable to effect the purpoſe. War was commenced by James, who invaded England, but by the exertions of the biſhop he was driven back to his own country. Shortly after Henry appointed biſhop Fox his ambaſſador to the court of Scotland, where he ſigned a ſeven-years truce between the two kingdoms. Henry now made overtures for a marriage between the king of Scotland and his own daughter Margaret, and Dr. Fox was ſent to negociate the important buſineſs, which was concluded in the beginning of the year 1501-2. During this negociation he was choſen chancellor of the univerſity of Cambridge; and about the ſame time tranſlated to the vacant ſee of Wincheſter. Here he ſpent the remainder of his days in great affluence and proſperity, unleſs when ſtate affairs required his attendance at court, or he was engaged in conducting negociations of moment with foreign powers. During the reign of Henry VII. no important affair was undertaken without his advice and ſanction, but when Henry VIII. ſucceeded to the crown, the influence of biſhop Fox began to decline, and that of Thomas Howard, earl of Surrey, to prevail. To ſupplant his rival the biſhop introduced Wolſey, one of his chaplains, to court, who ſpeedily ſucceeded in wholly engroſſing the favour of the king. No ſooner did he find himſelf ſecure of the royal attachment, than he ſeized the ſole adminiſtration of public affairs, and found means of driving from court all who could give him any jealouſy or uneaſineſs, by dividing with him the monarch's eſteem. Biſhop Fox, though not wholly neglected, was mortified and chagrined at ſeeing his own intereſts completely undermined by Wolſey, whom he had been the means of raiſing to power, and receiving from him inſults and mortifications which his ſpirit could not brook, retired to his dioceſe in diſcontent and diſguſt. Here he did not live for himſelf alone, but was ever projecting ſome plans that might be beneficial to poſterity. He founded Corpus Chriſti college, Oxford, and eſtabliſhed ſchools at Taunton, where he had a manor, as biſhop of Wincheſter, and at Grantham, near his native place. Towards the cloſe of life he had the misfortune to loſe his ſight, of which circumſtance Wolſey, then a cardinal, wiſhed to take advantage, by perſuading him to reſign his biſhopric, and to receive, in its ſtead, a penſion from the crown. Fox, indignant at the propoſal, ordered the perſon ſent to him on the buſineſs to tell his maſter, "that though he was blind, and was not able to diſtinguiſh white from black, yet he could diſcern between true and falſe, right and wrong: and plainly ſaw, without eyes, the malice of that ungrateful man, which he did not ſee before. That it behoved the cardinal not be ſo blinded with ambition as not to foreſee his own end." The biſhop died in the year 1528, at a very advanced age, leaving behind him a character very eminent for political ſagacity, and the ability and addreſs with which he conducted the moſt important and difficult ſtate negociations of his time. He has been regarded as a patron of learned men, and is certainly entitled to gratitude on account of the uſeful inſtitutions which he founded for the encouragement of literature and ſcience. One letter is preſerved in Strype's Memorials, which he wrote on the ſubject of the cardinal's intended general

neral viſitation and reformation of the Engliſh clergy. That day, he ſays, he wiſhed as ardently to ſee, as Simeon did to behold the Meſſiah; and he adds, that for three years paſt, almoſt all his ſtudies, labours, thoughts, and cares, had been directed to that object within his own particular juriſdiction. Biog. Brit.

Fox, Edward, likewiſe a prelate and ſtateſman, was born at Durſley, in Glouceſterſhire; educated at Eton, and purſued his more advanced ſtudies at King's college, Cambridge, to which he was admitted in the year 1512. He was ſoon found to poſſeſs great talents, and to be eminently qualified for ſtations of activity and confidence. In the year 1528 he was elected provoſt of his college, and retained that poſt to the time of his death: in the ſame year Wolſey appointed him, jointly with Gardiner, afterwards the biſhop of Wincheſter, embaſſador to Rome to obtain the conſent of pope Clement VII. for the divorce of Henry VIII. from his queen Catherine of Arragon. After his return he was appointed to embaſſies both in France and Germany; and having accompliſhed theſe to the ſatisfaction of his maſter, he was ſent to Cambridge with Gardiner, and, notwithſtanding the oppoſition they met with, they obtained the univerſity's determination, that "the king's marriage was againſt the law of God." From this time he was in high favour, and received as a remuneration for his ſervices valuable preferments in the church, and in 1535 he was promoted to the biſhopric of Hereford. In the ſame year he was ſent to the proteſtant princes then aſſembled at Smalkalde, whom he exhorted to unite in point of doctrine with the church of England. After three months' negociation nothing was effected, and the biſhop returned to England in 1536, and having enjoyed his biſhopric ſomewhat leſs than three years, he died at London in the year 1538. As an author he left behind him a treatiſe "De vera differentia regiæ Poteſtatis et eccleſiaſticæ, et quæ ſit ipſa veritas utriuſque," 1534, which was afterwards tranſlated into Engliſh by Henry lord Stafford. He wrote "Annotations upon the Mantuan poet." There is alſo extant an "Oration" of his, and a joint letter from him and Gardiner, concerning their proceedings at Cambridge. This is among the collection of records at the end of the firſt volume of Burnet's hiſtory of the Reformation. He was a man of great talents and learning, an excellent preacher, but choſe rather to devote himſelf to the buſineſs of a ſtateſman than to the duties of the clerical character. He was a ſecret well wiſher to the reformation, and contributed privately, by his influence and advice, to the furtherance of the meaſures by which it was ultimately effected. Biog. Brit.

Fox, John, was born at Boſton, Lincolnſhire, of reſpectable parents, in the year 1517. At ſixteen years of age he was entered at Brazen-noſe college, Oxford; in the year 1538, he took his firſt degree, and, on account of his extraordinary proficiency, he was, in 1543, elected a fellow of Magdalen college, and proceeded M. A. Early in life he diſcovered a turn for poetry, and wrote ſeveral Latin comedies; of which one, entitled, "De Chriſto triumphante," was publiſhed at London and at Baſil, and tranſlated by Richard Day, ſon of the famous printer, in the reign of queen Elizabeth. Fox had a ſtill ſtronger predilection for divinity than for poetry, and ſtudied with the utmoſt fervour and aſſiduity, till he had made himſelf maſter of all the controverſies that then agitated the Chriſtian world, and to diſcover from his own inquiries what was truth. For this purpoſe he had, when he was thirty years of age, read over all the Greek and Latin fathers, the ſchoolmen, the decrees of councils and conſiſtories; and had acquired an accurate knowledge of the Hebrew language. In the courſe of his inquiries, he became ſatisfied of the errors of popery; and being reſolved to follow truth wherever ſhe might lead him, he abſtained from the eſtabliſhed worſhip of the country. His enemies, ſuſpecting the fact, charged him with hereſy, for which he was tried, and found guilty. He was expelled the houſe, and told that he might conſider it a mark of great clemency and particular favour towards him, that the puniſhment did not extend to take away his life. By this event, Mr. Fox loſt the favour of his friends, who were alarmed at being ſuppoſed to countenance and protect a perſon convicted of ſo great a crime. His father-in-law, alſo, who was entruſted with the care of his property, took advantage of his ſituation to withhold from him his paternal eſtate; thinking, no doubt, that as he was become obnoxious to the penalties of the law himſelf, he would find it difficult to maintain his rights, ſhould he appeal to the courts for that purpoſe. Mr. Fox was now on the verge of great diſtreſs, when he unexpectedly met with a friend in ſir Thomas Lucy of Warwickſhire, who appointed him tutor to his children. In the houſe of this gentleman he continued till his pupils were grown up, during which time he had married the daughter of a citizen of Coventry. A few years before the death of Henry VIII. he went to London; but not being able to meet with employment, he was again reduced to extreme diſtreſs, and in danger of periſhing through want. From an unknown perſon, who had ſeen him ſitting one day in St. Paul's cathedral, bent down under his diſtreſſes, he received relief; and in a very ſhort time afterwards he was ſo fortunate as to be taken into the ducheſs of Richmond's family, to educate the children of her brother, the famous Henry Howard, earl of Surrey, who were entruſted to her care, when their father was ſent to the Tower by Henry VIII. In this noble family he continued to reſide during the remainder of Henry's reign, through the whole of that of Edward, and part of that of Mary; being protected in the latter period by the duke of Norfolk, who had been one of his pupils. He is ſaid, by Anthony Wood, to have been reſtored to his fellowſhip in Magdalen college, under the reign of Edward VI., and to have been the firſt perſon who preached the reformed doctrines at Ryegate. The bloody-minded Gardiner was thirſting after the life of this excellent man; and it was with the utmoſt difficulty that he eſcaped the ſnares laid for him by that cruel prelate, who had iſſued warrants for apprehending him and his wife. At length they reached the continent in ſafety, and took up their reſidence at Baſil. Here he gained a ſubſiſtence, by correcting the preſs for Oporinus, a celebrated printer; and here he formed the deſign of his "Acts and Monuments of the Church." He had, ſome time before this, publiſhed at Straſburgh, "Commentarii Rerum in Eccleſia geſtarum, maximarumque per totam Europam Perſecutionum a Wicleví Temporibus ad hanc uſque Ætatem Deſcriptarum," in one book; to which he now added five others, and they were all printed at Baſil, in 1559, in folio. In Germany, Mr. Fox joined the other Engliſh exiles in publicly uſing the liturgy adopted by the French and Genevan reformed churches, in preference to that ordered by king Edward. On the acceſſion of queen Elizabeth, Mr. Fox returned to his native country, where he was kindly received by his former pupil, the duke of Norfolk, who maintained him at his houſe as long as he lived, and ſettled a penſion upon him at his death. By the intereſt of Cecil, he had formerly obtained a prebend in the church of Saliſbury: ſo high did he now ſtand with people in power and rank, that he might have had any preferment; but he choſe to decline farther

elevation,

elevation, becauſe he could not conſcientiouſly ſubſcribe to the articles enforced by the eccleſiaſtical commiſſions, and becauſe he alſo diſapproved of ſome of the ceremonies of the church. To give countenance to conformity, Mr. Fox was called on by archbiſhop Parker to ſubſcribe. He attended, according to the ſummons; but, in reply to the command, he took from his pocket a Greek Teſtament, and ſaid, "To this will I ſubſcribe." And on another occaſion, when he was required to ſubſcribe to the canons, he refuſed, ſaying, "I have nothing in the church ſave a prebend at Saliſbury, and much good may it do you, if you will take it from me." He was, however, too highly reſpected by the biſhops, moſt of whom had been his fellow-exiles, to be further moleſted; and he was allowed to retain his prebend till his death. In 1564, he addreſſed a Latin panegyric to the queen, upon her indulgence to certain divines, who ſcrupled ſtrict conformity, and yet were ſuffered to hold their livings, and retain their dignity in the church. This moderation was not always the characteriſtic of the queen. In 1575, a furious perſecution was commenced againſt the baptiſts. A number of them were apprehended in a private houſe, where they were aſſembled for worſhip, and afterwards tried for hereſy. Eleven were condemned to die; and of theſe nine were baniſhed, and two ſentenced to the flames. Mr. Fox underſtood too well the nature of Chriſtian liberty, and the principles of toleration, not to feel moſt acutely for the victims about to be ſacrificed at the ſhrine of prejudice and intolerance. He wrote a Latin letter to the queen, in which he expoſed the cruelty and iniquity of puniſhing with death perſons guilty of error, or obſtinacy of judgment; and ſhewed how inconſiſtent ſuch conduct was with the benevolent ſpirit and pure precepts of the goſpel. His interceſſion was without effect; for though Elizabeth had ſo high a reſpect for Fox as conſtantly to denominate him "Father," yet in this inſtance ſhe reſolved to ſhew no mercy, as it was falſely called, unleſs the unfortunate men ſhould recant. Mr. Fox, as we have ſeen, would accept of no higher preferment; nevertheleſs he was frequently engaged as a preacher, and never omitted an opportunity of exerting his talents, where he thought he could promote the real intereſts of religion. His piety and zeal were ardent and animated; his moral conduct ever correſponded with his principles, and was irreproachable. He was modeſt, humble, obliging, and remarkable for his humanity and kindneſs to the poor. He died in his 70th year, on the 18th of April, 1587, generally eſteemed and lamented by all who knew him. He was author of many pieces, beſides thoſe which have been already noticed: their titles, with their ſeveral dates, are given in the Biographia Britannica. We may here refer to his "Tables of Grammar," which were at firſt recommended by eight lords of the privy council, but which were ſoon laid aſide on account of their brevity; being, it is ſaid, as much too ſhort for general uſe, as king Henry VIII.'s grammar was too long. "The four Evangeliſts, in the old Saxon tongue, with the Engliſh verſion added to it." But the grand work of this good man is his "Hiſtory of the Acts and Monuments of the Church," generally known by the title of "Fox's Book of Martyrs." This, as we have ſeen, was begun at Baſil; but the greater part of it was written after the author's return from exile to his native land, where he had acceſs to ample authorities, and could avail himſelf of the teſtimonies of living witneſſes. He was eleven years in completing the great undertaking, and, according to Whitgift, he "very diligently and faithfully laboured in this matter, and ſearched out the truth of it as learnedly as any man has done." Camden gives the following teſtimony to Mr. Fox, and his "Acts and Monuments:" "Ex eruditorum numero obiit Johannes Foxus Oxonienſis, qui eccleſiaſticam Angliæ hiſtoriam, ſive martyrologiam, indefeſſo veritatis ſtudio, primum Latinè, poſtea Anglicè auctius, magna cum laude contexuit." The "Acts and Monuments" were firſt publiſhed in one thick volume, folio, in the year 1563; but in 1583, a fourth edition of it was printed at London, in two volumes, folio; and in the middle of the following century it came out in three volumes. The ninth edition of this work appeared in 1684, in three volumes, folio, with copper-plate cuts, inſtead of the wooden ones which had been interwoven with the former impreſſions. In queen Elizabeth's time, an order was made that this book ſhould be placed in the common halls of the archbiſhops, and of all biſhops, deans, archdeacons, heads of colleges, &c. It was, indeed, ſo highly valued by proteſtants in general, that it was not unuſual to have it kept in churches. We have ſeen a copy in a country church, faſtened by chains in ſome conſpicuous place, for the benefit of thoſe who reſorted to the place for the purpoſes of devotion and information. The papiſts, as was natural, did all in their power to ruin the credit of the work, and injure the reputation of the author; and ſome proteſtants have taken every opportunity to undervalue and depreciate it, aſſerting that the facts are deſignedly miſrepreſented. Such a charge led to a ſtrict examination of the merits of the performance; and it was acknowledged by Burnet and Strype to be a faithful record of the events that took place, not indeed without defects, not wholly without error, but free from every imputation of deſigned miſrepreſentation: and, to the honour of the author, he was ever ready to correct ſuch miſtakes as were pointed out to him. This ſubject is diſcuſſed with candour and ability in the Biographica Britannica, to which the reader is referred.

Fox, George, founder of the ſociety of friends, commonly called quakers, was born at Drayton, in Leiceſterſhire, in 1624. His father was a weaver, much reſpected by his neighbours for his piety and virtues; and he ſeems to have taken great pains in educating his ſon in the principles of piety and virtue. He was, at a proper age, apprenticed to a dealer in wool and grazier, and was a good deal employed in keeping ſheep: an occupation that afforded him opportunities for contemplation and reflection. When he was about nineteen years of age, he experienced much trouble and anxiety on obſerving the intemperance of ſome perſons, profeſſing to be religious, with whom he had gone to an inn for refreſhment; and on the following night he was perſuaded that a divine communication was made to him, urging him to forſake all, to ſeparate himſelf from the old and the young, and devote his life to the duties of religion. Satisfied with the divine command, he renounced ſociety, quitted his relations, dreſſed himſelf in a leathern doublet, and wandered about from place to place. At length he reached the metropolis, when his friends interfered, and beſought him to return and ſettle in ſome regular employment. He returned, but did not remain with them many months; determining to embrace an itinerant mode of life. He faſted much and often, walked abroad in retired places, with no other companion but the bible, and ſometimes ſat in the hollow of a tree for a day together, and walked in the fields by night, as if in a ſtate of deep melancholy. He occaſionally attended upon public teachers, but did not derive that benefit from them that he looked for: and hearing, as he ſuppoſed, a voice exclaiming, "There is one, even Chriſt Jeſus, that can ſpeak to thy condition," he forſook the uſual outward means of religion; contending that as God did not dwell in temples made with hands, ſo

the

the people ſhould receive the *inward* divine teaching of the Lord, and take that for their rule of life. About the year 1648, he felt himſelf called upon to propagate the opinions which he had embraced, and commenced public teacher in Mancheſter, and ſome of the neighbouring towns and villages, inſiſting on the certainty and efficacy of experiencing the coming of Chriſt in the heart, as a light to diſcover error, and the knowledge of one's duty. He now made more extenſive journies, and travelled through the counties of Derby, Leiceſter, and Northampton, addreſſing the people in the market-places, and inveighing ſtrongly againſt injuſtice, drunkenneſs, and the other prevalent vices of the age. About this time he apprehended that the Lord had forbidden him to take off his hat to any one; and required him to ſpeak to the people in the language of *thou* and *thee*; that he muſt not bend his knee to earthly authorities, and that he muſt, on no account, take an oath. His peculiarities expoſed him to much cruel treatment, and his zeal frequently was the cauſe of impriſonment and the moſt inhuman uſage. At Nottingham, while the miniſter was exhorting the people to try all doctrines, opinions, and religions, by the holy ſcriptures, Fox ſtood up, and exclaimed, "Oh no! it is not the ſcriptures, but the holy ſpirit, by which opinions and religions are to be tried; for it was the ſpirit that led 30 people into all truth, and gave them the knowledge of it." Such an interruption was not likely to be endured; he was not only turned out of the church, but thrown into priſon, where he was detained during the pleaſure of the magiſtrates. At Manſfield, on a ſimilar occaſion, he was impriſoned, thrown into the ſtocks, and afterwards expoſed to the madneſs of an infuriated mob, ſo that he ſcarcely eſcaped with his life. At Derby he was committed to priſon for ſix months, under the pretence of having uttered divers blaſphemous opinions; and at the expiration of the term, refuſing to enliſt as a common ſoldier, he was ordered into the dungeon, and confined for another term of ſix months. At Derby, the followers of Fox were firſt denominated "quakers," as a term of reproach, either on account of the trembling accent uſed in the delivery of their ſpeeches, or, becauſe, when brought before the higher powers, they exhorted the magiſtrates and other perſons preſent "to tremble at the name of the Lord." At Lancaſter, Carliſle, and other places, Fox met with ſimilar uſage, and in 1655 he was ſent priſoner to Cromwell, who contented himſelf with obtaining a written promiſe that he would not take up arms againſt him or the exiſting government; and having diſcuſſed various topics with mildneſs and candour, he ordered him to be ſet at liberty. Fox probably now felt himſelf bold in the cauſe, recommenced his miniſterial labours at London, and ſpent ſome time in vindicating his principles by means of the preſs, and in anſwering the books circulated againſt the ſociety which he had founded, and which began to attract public notice in many parts of the kingdom. Notwithſtanding the moderation of Cromwell towards Fox, he was perpetually ſubject to abuſe and inſult, and was frequently impriſoned and hardly uſed by magiſtrates in the country whither he felt himſelf bound to travel: and more than once he was obliged to ſolicit the interference of the Protector, to free him from the perſecutions of ſubordinate officers. Once he wrote to Cromwell, ſoliciting his attention to the ſufferings of his friends; and on hearing a rumour that he was about to aſſume the title of king, Fox ſolicited an audience, and remonſtrated with him very freely upon the meaſure, as what muſt bring ſhame and ruin on himſelf and his poſterity. He alſo addreſſed a paper to the heads and governors of the nation, on occaſion of a faſt appointed on account of the perſecutions of the Proteſtants abroad; in which he embraced the opportunity that ſuch appointment offered, of holding up, in proper colours, the impropriety and iniquity of perſecution at home. The hiſtory of Fox, for ſeveral years previouſly to 1666, conſiſts of details of his miſſions, and accounts of his repeated impriſonments. In this laſt-mentioned year he was liberated by order of the king, and he immediately ſet about forming the people who had embraced his doctrines into a compact and united body: monthly meetings were eſtabliſhed, and other means adopted to provide for the various exigences to which they might be liable.

About the year 1669 he married Margaret, the widow of judge Fell, at whoſe houſe he had been entertained in his progreſs through Lancaſhire. The ceremony, on this occaſion, was according to that ſimple form which is practiſed to this day among the people of his perſuaſion. He only acquainted their common friends of their intention; and having received their approbation, they took each other in marriage, by mutual public declarations to that intent, at a meeting appointed for the purpoſe at Briſtol. After this Mr. Fox ſailed for America, where he ſpent two years in making proſelytes, and in confirming the faith and practice of thoſe who had already joined in his cauſe. Soon after his return to England he was taken into cuſtody, and thrown into Worceſter gaol, under the ridiculous charge of having "held a meeting from all parts of the nation, for terrifying the king's ſubjects." During his impriſonment he was ſeized with an alarming illneſs, which rendered his recovery very doubtful. His wife went to London to ſolicit his releaſe of the king, who was willing to grant it by means of a pardon. Fox, however, rejected the mode, as he conceived a pardon implied guilt: he choſe rather to ſtand a trial, by which he was honourably acquitted, though not till he had ſuffered more than a year's very ſevere confinement. He next went to Holland, and on his return, a ſuit was inſtituted againſt him for refuſing to pay tithes; his opponents were ſucceſsful, and he was obliged to ſubmit to the conſequences. In 1684, Fox again viſited the continent, and upon his return he found his health and ſpirits too much impaired by inceſſant fatigues, and almoſt perpetual perſecutions, to contend any more with his enemies, he accordingly lived more retired; and in 1690 he died, in the ſixty-ſeventh year of his age; having, however, performed the duties of a preacher, till within a few days of his deceaſe. His writings, excluſive of a few ſeparate pieces, which were not printed a ſecond time, were collected in 3 vols. folio: the firſt contains his "Journal;" the ſecond a collection of his "Epiſtles;" the third, his "Doctrinal Pieces." Fox was a man of good natural talents, and thoroughly converſant in the ſcriptures. The inceſſant zeal which he exhibited through life, affords abundant evidence of his piety, ſincerity, and purity of intention; and his ſufferings bear teſtimony to his fortitude, patience, and reſignation to the Divine will. William Penn, ſpeaking of him, ſays, that "he had an extraordinary gift in opening the ſcriptures, but that, above all, he excelled in prayer. The reverence and ſolemnity of his addreſs and behaviour, and the ferventneſs and fullneſs of his words, often ſtruck ſtrangers with admiration." He alſo mentions, in terms of high commendation, his meekneſs, humility, and moderation; and he adds that he was civil beyond all forms of breeding; in his behaviour very temperate, eating little, and ſleeping leſs, though a bulky perſon. Toulmin's edit. of Neal's hiſt. of Puritans. Gen. Biog.

Fox,

FOX.

Fox, Charles James, one of the moſt eminent ſtateſmen that ever lived, was third ſon of Henry Fox, afterwards lord Holland, by lady Georgiana Carolina Lennox, eldeſt daughter to Charles, ſecond duke of Richmond, and was born January 13, 1749. Being intended for public life, he was ſent firſt to Weſtminſter-ſchool, and afterwards to Eton, when that ſeminary had attained a high degree of celebrity, under the direction of Dr. Bernard, the provoſt. Here Mr. Fox was not only diſtinguiſhed with regard to claſſical attainments; but he was obſerved to be equally ardent in the purſuit of amuſements and pleaſures. Dr. Newcombe, the late learned primate of Ireland, was his private tutor, and, to the laſt hour of his life, is ſaid to have thought more highly of the honour of having been inſtrumental in educating ſo great a ſtateſman as Mr. Fox, than of any other circumſtance in his life. His pupil obtained a decided ſuperiority in every claſs which he joined. As his father hoped to introduce him early into public life, and was anxious to form him for a man of buſineſs, he had always encouraged him to think and to ſpeak freely; hence he acquired the habit of a ready elocution. In every enterprize at ſchool, which required an orator, he was generally ſelected, and nothing can better ſhew the ſtrength of his mind, and of his conſtitution, than, that by turns, literature and diſſipation appeared to engroſs his whole attention, and yet that the apparent preference of the one was not allowed to interfere with the other. He was never ſatisfied with mediocrity in any purſuit; whatever he regarded as deſerving his attention, he followed with ardour. At Eton he formed his early friendſhips with many of the moſt eminent characters of the age, ſome of whom foreſaw in their contemporary all the ſeeds of future greatneſs, and of that renown for which he will be celebrated in every ſucceeding period of Britiſh and European hiſtory. It was not merely the riſing ſuperiority of talents by which he was diſtinguiſhed from his ſchool-fellows: the kindneſs of his heart, and the mildneſs of his manners were equally conſpicuous. He demonſtrated, by the moſt deciſive traits of character, his attachment to the finer ſenſibilities of humanity, by always eſpouſing, if it could be done with propriety, the weakeſt ſide, in thoſe conteſts which occaſionally diſturb the ſociety of young people He was frequently called upon to preſide as judge in diſputes, and when he ſaw any one borne down by partiality and prejudice, he exerted his youthful eloquence in favour of the ſide of juſtice. From Eton he went to Oxford, where he entered himſelf at Hertford college, and is ſaid to have ſtudied more than ten hours a day during the whole term. The uniformity of a college life did not long agree with the ardour of his mind, and after ſome time he ſet out on the uſual tour of Europe. No young man was ever better qualified to derive inſtruction from thoſe ſcenes which are ever preſented to the mind of the traveller; and though he did not refrain from indulging in the diſſipations, over which his rank and fortune gave him the command, yet he did not fail to acquire that intimate knowledge of the world and of human nature, which fitted him for the moſt exalted rank in the ſtate, and prepared his mind for the reception of thoſe enlarged principles by which, with the exception of the firſt year or two of his political life, he was diſtinguiſhed, as the zealous and ſteady friend to the liberties and happineſs of the people; by which he was, as it were, habitually the advocate of the oppreſſed, whoſe cauſe he pleaded with a force and eloquence unknown in modern times. An unfortunate attachment to the gaming table, which can never be paſſed over in ſilence, nor ſpoken of without becoming cenſure, was the principal error of Mr. Fox's youth. Before he was eighteen years of age he had laviſhed away large ſums of money, and had contracted very heavy debts. His father, being apprized of theſe exceſſes, urged his favourite ſon to return home; he complied, though with ſome degree of reluctance. From the faſcinating theatre of diſſipation and pleaſure, he was tranſplanted into that of oratory and politics; if the former had been more attractive, and apparently more accordant to his mind and habits, the latter was more important and honourable, and that on which he was deſtined to act a part that can never be forgotten, and never ſufficiently applauded. Lord Holland, well knowing the lively and impetuous diſpoſition of his ſon, foreſaw that a ſeat in parliament would be likely to detach him from a courſe which threatened irreparable injury to his conſtitution, and ruin to his fortune; he, accordingly, in the election of 1768, when his ſon was but nineteen years old, procured him the return for the borough of Midhurſt, which was then under the patronage of his lordſhip, but which at preſent is under that of lord Carrington. By the laws of England, a perſon under age is not deemed competent to judge for himſelf, much leſs to make laws to govern others; and on this account our youthful ſenator was ineligible to a ſeat in the houſe of commons. The circumſtance ſeems to have been wholly overlooked by the ſpeaker, and by that "committee of privileges," which is appointed by every parliament as the conſervator of the rights of the commons of Great Britain. Such an overſight can ſcarcely be accounted for; his attachments were ſuppoſed, from the conduct of his father, to be favourable to the exiſting miniſtry, whoſe power and influence were, every day, attacked by an oppoſition as formidable for rank and talents as ever exiſted in the country. It is probable, yet we own there are no particular facts to bear us out, if the ſuppoſition be denied, that the conciliating manners, which, it is acknowledged on all hands, attracted the admiration, and even challenged the good will and affection of every perſon who knew him, prevented any meaſures from being taken to diſpoſſeſs him of his ſeat in parliament.

In the debates and proceedings of parliament, which we have carefully collated, from that period to the deceaſe of Mr. Fox, we do not find that he took any part in the diſcuſſions till the 10th of January 1770, when he was within three days of attaining the full age, required by cuſtom and by law, to entitle him to give his opinion in the houſe. Whether he had voted before this period, we have no means of aſcertaining, becauſe it ſhould ſeem that even now he defended the meaſures of the adminiſtration, whoſe names, in the diviſions of the houſe, are rarely mentioned, though it has ever been the cuſtom to record the names of thoſe who dare, in bad times, to ſtand in a minority, and to ſhare in the obloquy which weak and vulgar minds are apt to attach to the conduct of men who are ſeeking their country's welfare at the expence of their own eaſe and advancement in life. On the ninth of January 1770, there had been a warm debate of more than twelve hours in the houſe on his majeſty's ſpeech, which referred, among other topics, to the diſcontents exiſting about the meaſures of the Middleſex election: an amendment was moved "That the houſe would take into conſideration the cauſes of the unhappy diſcontents that prevailed in every part of his majeſty's dominions." On this, which was ſuppoſed as intended to annul the former reſolutions of the houſe, debates ran very high; the oppoſition held language which was deemed encroaching on the privilege of the houſe, and the reſpect due to it.

The

The oppoſition divided 138 to 254, and their names are given in the "Proceedings of Parliament," vol. v. p. 205—6. On the following day, when the addreſs was reported, previouſly to its being delivered to his majeſty, a ſimilar diſcuſſion took place, when the leaders of oppoſition took a moſt diſtinguiſhed part. Sir George Saville diſtinctly aſſerted, that "the houſe of commons had betrayed the rights of the people:" upon this he was called to order, and threatened to be ſent to the Tower; but another member, friendly to miniſters, endeavoured to ſoften matters, and to aſſume that the honourable baronet had ſpoken in the hurry of anger; which ſir George denied, and ſaid he would always uſe the ſame language when the ſame ſubject was diſcuſſed: and he added at another period of the debate, that he was as cool as he could be; "bring me," ſaid he, "to teſt, and I the matter will re-word, which madneſs would gambol from; therefore, ſtanding in my place, as member for the county of York, I do declare, that this houſe of commons has betrayed the rights of the nation." On this, Mr. Fox replied in a very ſhort ſpeech, "That the licence gentlemen had taken in their language yeſterday and to-day, ſeemed as if the old decent freedom of debate was at an end, and that they were endeavouring to eſtabliſh new forms." He then explained away much of the force of the addreſs and of his majeſty's ſpeech, which gave Mr. Burke the opportunity of ſaying, by way of a cloſe to the diſcuſſion, "that it was not what we meant, but how the people out of doors would take it; however, he was glad to hear that the houſe meant nothing by their addreſs." Theſe facts are introduced to ſhew that Mr. Fox began his parliamentary career by defending and juſtifying the meaſures of lord North's adminiſtration; yet he was never that violent party-man, on this ſide, ſuch as he has been repreſented: he ſeems to have taken no lead whatever, and no part in many of the weighty diſcuſſions agitated at this period. The reporters of the parliamentary debates for that ſeſſion did not look to him as a man of much conſequence in the ſcale; for in mentioning a motion made by Mr. Welbore Ellis, and which was ſeconded by Mr. Fox, they only ſay "Mr. C. Fox ſeconded the motion in a lively, academical manner, of ſtating and taking off arguments uſed in favour of the bill;" while to every other ſpeaker on the occaſion, many of whoſe names have long ſince been buried in everlaſting oblivion, they have aſſigned comparatively large portions of their work to diſplay the arguments. Early in the next ſeſſion of parliament we find him juſtifying the conduct of miniſters: ſtill he is only repreſented as "diſplaying great ingenuity, in endeavouring to confound the reaſonings of his opponent, and moving the previous queſtion." But on a ſubſequent day, December 6, when Mr. Serjeant Glynn moved "That a committee be appointed to inquire into the adminiſtration of criminal juſtice, and the proceedings of the judges of Weſtminſter-hall, particularly in caſes relating to the liberty of the preſs, and the conſtitutional power and duty of juries," Mr. Fox ſpoke decidedly againſt the motion; as he did on ſome other occaſions, for which, no doubt, he was in after-life aſhamed. On the 27th of February 1771, on a diſcuſſion of the *nullum tempus* act, as it referred to the claims of ſir James Lowther, Mr. Fox burſt forth in a ſtrain of manly eloquence, "I take ſhame to myſelf," ſays he, "that I have not riſen ſooner to declare my ſentiments on this important queſtion; for I think it diſgraceful in any man to ſit ſilent on ſuch an occaſion, who ever had the uſe or faculty of ſpeaking in this houſe: but, ſir, my ſilence was owing to my aſtoniſhment; I was amazed! I was confounded! for though I ſaw this bill at firſt in the ſame light in which I now behold it, yet I endeavoured to perſuade myſelf that I muſt rather be miſtaken, than that any thing ſo bad, ſo violent, ſo lawleſs, ſo monſtrous, could be advanced by ſuch men as thoſe who propoſed this bill. But I could not long remain undecided; I ſoon beheld the propoſition in all its naked, genuine deformity: then, ſir, as I was firſt ſtruck dumb with aſtoniſhment, I was ſeized with horror and indignation. Who, ſir, that has a conſcience to revere juſtice, a ſenſe of liberty, or a regard for the conſtitution, can liſten, without feeling an honeſt zeal to defeat a propoſition which, at one blow, deſtroys our conſtitution, our liberty, and our laws! Gentlemen are loud in their clamours againſt miniſterial influence. I avow the ſyſtematic ſupport of that miniſter in all his meaſures, who has my good opinion and confidence; but that miniſter ſhall never have my aſſiſtance and ſupport, who ſhall dare to propoſe what theſe gentlemen, who are ſo proud of their oppoſition to miniſters, now propoſe." After this open and unreſerved avowal in favour of the courſe purſued by lord North, it was to be expected he would not be long unnoticed; accordingly, we find him in a very ſhort time advanced to a ſeat at the admiralty board, which he occupied a few months only, when, from cauſes not diſtinctly known, he reſigned his office; but towards the end of the year 1772, or early in the following year, he was appointed one of the lords of the treaſury. On this occaſion he was violently aſſailed as a placeman, bound to vote for every meaſure that the miniſter might propoſe; he denied the charge, avowing himſelf a free man, and that he would never ſupport the meaſures of government longer than while he believed they were calculated to promote the welfare of the Britiſh empire; and opportunities were not wanting in which he exerciſed this right. Of theſe, not the leaſt memorable occurred during the debate on the bill brought into the houſe of commons by that excellent man ſir William Meredith, to give relief from ſubſcription to the thirty-nine articles. On this occaſion Mr. Fox voted againſt the miniſter, and delivered an admirable ſpeech in favour of religious liberty; and to the principles which he then avowed, he firmly and uniformly adhered to the laſt hour of his life. Mr. Fox was no longer in high favour with the miniſter, but he ſtill gave him his general ſupport and vote, though he had a mind ſuperior to go all the lengths of a party-man: he muſt at all times think for himſelf, and ſometimes, as we have ſeen, he claimed to act according to his own judgment, which is ill reliſhed by a man whoſe motto muſt be "aut Cæſar aut nullus." Mr. Fox's immediate removal from the treaſury was not owing to any oppoſition to lord North's meaſures, but to a difference of opinion as to the beſt mode of carrying them into effect. The miſunderſtanding aroſe reſpecting the committal of Mr. H. S. Woodfall, the printer of the Public Advertiſer, who had been brought to the bar of the houſe for inſerting a letter ſuppoſed to have been written by the Rev. J. Horne, now J. Horne Tooke, in which moſt unjuſtifiable liberties had been taken with the character of the ſpeaker, ſir Fletcher Norton. Mr. Woodfall having given up the author, and thrown himſelf on the mercy of the houſe, it was moved by Mr. Herbert that he ſhould be committed to the cuſtody of the ſerjeant at arms. Mr. Fox, at that period a great ſtickler for the privileges of the houſe, avowed that the puniſhment was not ſufficiently ſevere, and moved "that he be committed to Newgate, as the only proper place to which offenders ſhould be ſent; though hints," he ſaid, "had been thrown out that the ſheriffs would not admit him." To this lord North replied, that he was very ſorry (he undoubtedly meant *angry*) that hints had been thrown out of what the ſheriffs would do; he hoped there were no perſons who would diſpute the power of that houſe;

houſe; he therefore moved that the printer be committed to the Gate-houſe, as he thought it imprudent to force themſelves into a conteſt with the city. Mr. Herbert carried his motion in oppoſition to the others, by a majority of 152 to 68, to the great diſpleaſure of lord North, who aſſerted that it was entirely owing to the interference of Mr. Fox that he was left in a minority.

It was on the occaſion of Mr. Horne's examination and triumph on this ſubject, that colonel Barré ſeized the opportunity of widening the breach between the miniſters, by ſarcaſtically jeering the premier with want of ſucceſs in the buſineſs; "At the firſt commencement of this buſineſs," ſaid the colonel, "I augured that it would end ill, and I laſt night felt inconceivable pain for the noble lord; his troops were no more prepared to defend than to fight for him. I know ſome little matter about the arrangement of troops, but in my life I never ſaw a body of regulars cut ſo wretched a figure! The noble lord has been charged with what I never ſhould have ſuſpected him guilty of, a precipitancy. I hope he will take his ſpirited friend's advice (Mr. Fox) and learn a little caution. Advice, whether coming from a grey or a green head, if good, ſhould be followed." And again, "We have heard a deal of ſound law; I wiſh we had a little more ſound ſenſe from the other ſide of the houſe. I have every thing to hope from the noble lord; he is at preſent moſt happily ſituated, for if he wants law, he has but to look at the left (to Mr. Wedderburne); if he ſtand in need of common ſenſe, his ſpirited friend on the right (Mr. Fox) can abundantly ſupply him."

This was on the 17th of February 1774, and in two days afterwards, while he was actually engaged in converſation with his lordſhip on other ſubjects in the houſe of commons, he received the following laconic, and, as he deemed it, contemptuous epiſtle, by the hands of one of the meſſengers of the houſe.

"His majeſty has thought proper to order a new commiſſion of treaſury to be made out, in which I do not ſee your name.

North."

Mr. Fox in a ſhort time entered avowedly the liſts of oppoſition to the miniſter. Sometimes, indeed, when the privileges of the houſe were concerned, he voted with the majority, yet he never failed to make him feel the power of his eloquence, and at length raiſed ſuch a force againſt him as to ſubvert his power, and almoſt to bring him to condign puniſhment. Mr. Fox had never given his voice for the coercive meaſures that were at this period adopted with regard to America; on this ſubject he was always conſiſtent, always the friend of liberty, and of the rights of our tranſatlantic brethren. To the firm ſtand which he now took may be aſcribed the foundation of that reputation which has been ſo beneficial to his country, and which has immortalized his name. He commenced his oppoſition in the midſt of circumſtances which enabled him to foreſee and foretel the impending calamities of the public, and that with an inſtantaneous deciſion which excited in his hearers a confidence in the reſolutions of his enlightened mind. For ſome years the adminiſtration had been rendered an object of popular jealouſy, owing to the uniform excluſion of the whig intereſt from any ſhare in the government: the influence of the crown had increaſed, and had been perpetually ſet in competition with the intereſts of the people. A number of oppreſſive ſtatutes, enacted againſt the intereſts, and contrary to the conſent of the colonies in America, had alienated the affections of their inhabitants, and juſt apprehenſions were excited of a civil war which was likely to endanger the ſafety of the whole empire. Notwithſtanding a majority in parliament was for coercive meaſures againſt the Americans, deſpondency ſpread itſelf over the country, and the public credit, as was evident from the ſtate of the funds, began rapidly to decline. In this ſtate of things, Mr. Fox joined the oppoſition, among whom were a Burke, a Camden, a Barré, and a Dunning, and at their head ſtood the virtuous and enlightened marquis of Rockingham. Mr. Fox now began to take the foremoſt rank among the ſpeakers of the houſe: his vaſt and comprehenſive mind ſoared beyond all his contemporaries; it embraced, as it were, intuitively, all ſubjects, and the habit of profound reflection had given him a degree of preſcience which ſeemed almoſt ſupernatural. His deep penetration, and his knowledge of cauſes and effects, were indeed greatly beyond that of any other man of the age: he viewed things in their diſtant relations and their remote conſequences. The experience, the fatal experience of an American and French revolution, has ſhewn that there was ſcarcely any great political meaſure which he reprobated that was not ultimately found miſchievous in its operations; and hardly any line of conduct which he adviſed, that time did not prove to be that which ought to have been purſued. "But his remonſtrances, his exhortations and ſuggeſtions, like the predictions of Caſſandra, to which they were often compared, were neglected and deſpiſed till the time in which they might have been executed had glided away." Thus, early in the year 1774, he oppoſed the introduction of the Boſton Port bill, and apologized for the conduct of the coloniſts; and on this and other occaſions he arraigned the proceedings of the miniſter in bold and energetic language: on the motion to repeal the tea act, April 17, he averred that this and other ſimilar bills had been brought in with the view to irritate, and declare war in America, "which," ſays he, looking to the treaſury-bench, "if you perſiſt in, I am clearly of opinion you will effect, or force it into open rebellion." It was now that the miniſter began to calculate the loſs he had ſuſtained, and the oppoſition to eſtimate the ſtrength it had acquired. The reflecting part of the nation were animated, and openly rejoiced to behold, in the perſon of a youthful ſenator, whom they had heretofore looked on as an enemy, a firm, intrepid advocate of the rights of the oppreſſed. On the 22d of June the parliament was diſſolved; one of its laſt, or rather its laſt act, was the Quebec bill, which was oppoſed by Mr. Fox, and which was ſaid in the houſe to contain, among others equally abſurd, the following propoſitions, *viz.* "That a ſtate of ſlavery is better than a ſtate of freedom:—that the popiſh religion was more congenial to the principles of Chriſtianity than the proteſtant:—that juries are unneceſſary, and therefore to be diſuſed:—that French laws are preferable to Engliſh; and that the conſtitution, which our anceſtors had preſerved with ſo much wiſdom, and eſtabliſhed at the expence of ſo much blood and treaſure, is to be deſtroyed." The act was however paſſed, and the parliament diſſolved; and upon the aſſembling of a new parliament Mr. Fox appeared in his place, as member for the ſame borough of Midhurſt, pledging himſelf to uſe every effort in bringing the miniſter to anſwer for the miſchief occaſioned by his incapacity. It was on this occaſion that colonel Barré characterized the late parliament as having "began their political life with a violation of the ſacred right of election in the caſe of Middleſex: they had died, he ſaid, in the act of popery, when they eſtabliſhed the Roman catholic religion in Canada, and they had left a rebellion in America as a legacy."

During the interval between the two parliaments, *viz.*

in July 1774, lord Holland died, bequeathing Mr. Fox, who by the death of his brother Henry was now a ſecond ſon, large property, and conſiderable eſtates in the Iſle of Thanet. At Kingſgate he had left him a houſe, built in imitation of Cicero's Formian villa on the coaſt of Baiæ. Mr. Fox, who had never been an economiſt, ſoon diſſipated the property bequeathed him by his father, and ſold Mr. Jenkinſon, the late lord Liverpool, a ſinecure place which had been obtained for him. Forlorn as his ſituation now was, and brought on by his own extravagance, or by his inclination for gaming, his mind did not bend under the calamity; it ſeemed to rebound from the fall, and inſtead of ſinking in deſpair, to have actually riſen into celebrity and even independence. Without following him ſtep by ſtep in his illuſtrious career, we may obſerve generally, that he ſpoke and voted during the whole conteſt in direct oppoſition to a criminal ſyſtem, which, as it had been fondly and fallaciouſly prognoſticated, was to produce the unconditional ſubmiſſion of the colonies, and lay them proſtrate at the feet of the mother country. At length all the evils that had been foreſeen were realized. America declared herſelf independent: France joined in the conteſt: the capture of Burgoyne and Cornwallis proclaimed the triumphs of liberty, and a new conflagration lighted in Europe, by the fire-brands that had been ſcattered by the Britiſh miniſtry in another hemiſphere, waſted the ſtrength and exhauſted the reſources of England.

At the general election in 1780, the family borough of Midhurſt having fallen into different hands, Mr. Fox, conſcious of his own powers, became candidate for the city of Weſtminſter, in which, after a violent conteſt, he ſucceeded, though oppoſed by the formidable intereſt of the Newcaſtle family, and by the whole influence of the crown. Being now the repreſentative of a great city, he appeared in parliament in a more dignified capacity, and acquired a conſiderable increaſe of conſequence to his political character. In himſelf he was ſtill the ſame: he now neceſſarily lived and acted in the boſom of his conſtituents: his eaſineſs of acceſs, his pleaſant, ſocial ſpirit, his friendly diſpoſition and conciliating manners, which appeared in all he ſaid, and the good temper which predominated in all he did, were qualities that rendered him the friend and acquaintance, as well as the repreſentative, of thoſe who ſent him into parliament: his ſuperior talents, and their powerful and frequent application to popular purpoſes, made him beſt known among political men, and gave him a juſt claim to the title ſo long applied to him, of "The man of the people."

The ſubjects of debate in the new parliament afforded the oppoſition fine opportunities for the diſplay of their eloquence: they had ever been diſtinguiſhed for integrity and talent, and now they became formidable by an increaſe of numbers. Miniſters were aſſailed in the houſe by arguments which they could neither repel nor contradict, and from without they were overwhelmed by the clamours of an indignant people; till at length lord North and his adherents, confounded, overwhelmed, and almoſt driven to deſpair, were obliged to reſign, and it was hoped that they would have been made really reſponſible for all the miſchiefs and bloodſhed that had occurred during their calamitous adminiſtration. The Rockingham party, however, contented themſelves with the defeat of their opponents. Mr. Fox obtained the office of ſecretary of ſtate for foreign affairs, and the marquis was nominated the firſt lord of the treaſury. The expectation of the nation was now raiſed to the higheſt pitch: with this party, they hoped to ſee an end to national calamity, and the intereſts of the country ſupported and maintained in all quarters of the globe. Much indeed was performed by them conſidering the ſhortneſs of their adminiſtration. Though they had ſucceeded to an empty exchequer, and a general and moſt calamitous war, yet they reſolved to free the people from ſome of their numerous grievances. Contractors, thoſe dead weights in the ſcale of corruption, were excluded by act of parliament from the houſe of commons: cuſtom and exciſe officers were diſqualified from voting at elections: all the arbitrary proceedings with reſpect to the Middleſex election were reſcinded; while a reform bill aboliſhed a number of uſeleſs offices. A more generous policy was adopted in regard to Ireland: a general peace was meditated, and America, which could not be reſtored, was at leaſt to be conciliated. In the midſt of theſe promiſing appearances, the marquis of Rockingham, who was the ſupport of the new adminiſtration, ſuddenly died, an event which afflicted the nation, and divided the friends of liberty. The council board was inſtantly torn in pieces by political ſchiſms: a diſpute, as had been foreſeen, immediately took place reſpecting the perſon who ſhould ſucceed as firſt lord of the treaſury. The candidates were lord Shelburne, afterwards marquis of Landſdowne, and the late duke of Portland; the former ſuppoſed to have the ear of the king, and a majority in the cabinet, was immediately entruſted with the reins of government, and Mr. Fox retired in diſguſt, declaring that "he had determined never to connive at plans in private, which he could not publicly avow." He now reſumed his ſtation in oppoſition, and joined the very man whoſe conduct he had for a ſeries of years deprecated as the moſt deſtructive to the intereſts of his country, and moſt baneful to the happineſs of mankind: while his former colleague, the earl of Shelburne, was buſied in concluding a peace with France, Spain, Holland, and the united ſtates of America. This nobleman, though by no means deficient in political wiſdom, had omitted to take thoſe ſteps which preceding miniſters had ever adopted to ſecure ſafety. A confederacy was formed againſt him by the union of the friends of Mr. Fox and lord North, known by the name of "The coalition," which proved in the event as impolitic, as it was odious to the great maſs of the people. It anſwered, however, the temporary purpoſe of thoſe who adopted it, by enabling them to ſupplant their rivals, and to ſeize upon their places. Their ſucceſs was, however, ephemeral; they had a majority in the houſe of commons, but the people at large were decidedly hoſtile to an union which appeared to them to be bottomed on ambition only, and deſtitute of any common public principle. It was aſſerted, with too much appearance of truth, that they agreed in no one great meaſure calculated for the benefit of the country, and the nation ſeemed to unite againſt them as one man. Their conduct in the cabinet led the ſovereign to uſe a watchful and even jealous eye upon their acts; and the famous India bill proved the rock on which they finally ſplit, and on account of which they forfeited their places. Mr. Fox had now to contend for the government of the empire with William Pitt, a ſtripling ſcarcely arrived at the age of manhood, but who nevertheleſs ſucceeded to the poſt of premier, and maintained the ſituation for more than twenty years.

The tide of popularity had ſet in ſo ſtrongly againſt Mr. Fox, that at the general election many of his moſt active friends and partizans loſt their ſeats in the houſe of commons, and he himſelf was forced into a long and expenſive conteſt for the city of Weſtminſter. He had, as we have ſeen, been originally returned for that place by the voice of the inhabitants, in oppoſition to the influence of the crown

united to that of ſome of the leading families. Now, though ſupported by the Portland and Devonſhire intereſts, he had to maintain a ſevere and very dubious ſtruggle, but after the lapſe of forty-ſeven days he appeared, at the cloſe of the poll, to have a majority of 236 votes in his favour. A ſcrutiny was demanded and obtained by his adverſary, by which Mr. Fox would have been excluded for a time from the houſe of commons, had he not been returned by the intereſt of ſir Thomas Dundas for ſome Scotch boroughs. At length his triumph was complete, the houſe of commons, after the ſcrutiny had continued from May to the following March, ordered the high bailiff to make his return, when the majority for Mr. Fox was 231, he having at this period loſt only five by the inveſtigation. At this election 12,301 electors polled, of whom 6126 gave their votes for Mr. Fox. A proſecution was commenced againſt the high bailiff; and a verdict was obtained, with 2000*l.* damages. From this period to his death, a long ſpace of twenty-five years, Mr. Fox had been gradually riſing in the eſtimation of his fellow citizens. He took an active and leading part in the proſecution of Mr. Haſtings, a meaſure that ſeemed abſolutely neceſſary to clear the honour of the nation, and to prove to the inhabitants of India, that in England they would ſtill find avengers of their wrongs. Mr. Fox had ever ſhewn himſelf a friend to peace, as well from the true principles of humanity, as to promote the intereſts of his country; and on two great occaſions his overbearing eloquence proved of the laſt importance to the nation; once when his rival, Mr. Pitt, at the inſtigation of the court of Berlin, wiſhed to wage an unprofitable war with Ruſſia, relative to the poſſeſſion of Oczakow; the other, when he urged a conteſt with Spain. And it is now a matter of aſtoniſhment, that a miniſter who derived all his credit from the management of the finances, laboured to impoveriſh the nation by two ridiculous but bloody conflicts, one of which had for its object the preſervation of the Turkiſh frontier, and the other a participation in the trade of cat-ſkins.

In the year 1788, Mr. Fox, diſguſted or wearied with public buſineſs, repaired to the continent, and after ſpending a few days with Gibbon the hiſtorian, at Lauſanne, entered the claſſic regions of Italy; ſcarcely had he time to look about him, when a meſſenger from the prince of Wales arrived, deſiring his immediate attendance in forming an adminiſtration, which the king's alarming and ſingular illneſs rendered neceſſary. Mr. Fox returned, but on the firſt day of his appearing in the houſe, he ſtarted an abſtract queſtion upon the ſubject of the prince's *right* to the regency, which cauſed very violent and protracted diſcuſſions, till at length his majeſty was reſtored to the poſſeſſion of his health, and a regency rendered unneceſſary. On this ſubject his rival contrived to take his ſtand on conſtitutional ground, which cauſed the oppoſition, with their leader, to loſe rather than gain popularity by the meaſure.

No ſooner had the French nation evinced a ſincere deſire to ſhake off the yoke of abſolute power, than Mr. Fox hailed the auſpicious dawn of riſing liberty. At firſt the two great rival chiefs, who agreed in nothing elſe, united cordially in this cauſe, and while one preſaged a long peace, the extinction of the national debt, and the proſperity of the empire; the other gloried in beholding a mighty people reſcued from the moſt oppreſſive ſervitude, and at the ſame time augured the happieſt reſults in favour of the human race. At length however, they became oppoſed to each other, and the moſt ſerious conflicts were the reſult of their diſcuſſions. Mr. Fox experienced the dereliction of many of his aſſociates, among others of Mr. Burke, the man from whoſe lips he had firſt imbibed the principles of freedom.

This was a circumſtance that affected him more than any other through life; he had ſeen his plans for the public good diſappointed; he had been deſerted by a crowd of political adherents; a thouſand times his heart and his motives had been ſlandered, ſtill he had abundant reſources in himſelf to bear up againſt the tide ſetting in againſt him. No oppoſition, no injuries could excite in him the ſpirit of revenge, or the principles of acrimony; even "when his friend, on whom he hung with almoſt idolatrous regard, broke from him in the paroxyſm of political madneſs, and with furious cruelty explored, in his attack on him, every avenue to pain, far from repelling enmity with enmity, he diſcovered his ſenſibilities of wrong only with tears, and he ſubſequently wept with a pertinacity of affection almoſt without example, over the ſepulchre of that very man, who had unrelentingly ſpurned all his offers of reconciliation, and who, with reference to him, had expired in the bitterneſs of reſentment."

War was commenced; to this, in every ſtage, Mr. Fox gave his decided negative, but Mr. Pitt, who was ſuppoſed to engage in it, at firſt, with reluctance, left no means untried to carry his meaſures with a high hand. Titles, offices, and honours were diſtributed with the utmoſt profuſion, the oppoſition benches were nearly deſerted, and his political rival, the ſubject of this memoir, was left almoſt alone to contend againſt a hoſt of foes. Conſcious of his integrity, and of the juſtice of the great principles on which he was acting, and at the ſame time ſeeing that his oppoſition was almoſt without effect, he determined to ſecede from parliament, and had evinced a wiſh to retire altogether from public buſineſs. But the entreaties of his friends, and the occurrence of new and ſingular events, prevented the meaſure. He again took his place in parliament at the head of an oppoſition, feeble in point of numbers, but formidable in reſpect to talents and abilities.

At length, after eighteen years, Mr. Pitt retired from office, and was ſucceeded by Mr. Addington, now viſcount Sidmouth, who concluded the peace of Amiens, and who on this occaſion received the ſupport of Mr. Fox and his friends. When a renewal of the conteſt was meditated, he expreſſed himſelf hoſtile to the meaſure, avowing that he thought the continuance of peace was infinitely deſirable, and that the preſervation of national honour was the only legitimate cauſe of war. In ſtrict conſiſtency, therefore, with this notion, when the royal meſſage was brought down to the houſe declaratory of hoſtilities, Mr. Fox expreſſed his opinion both againſt the war as unneceſſary, and againſt the criſis at which it took place, as impolitic. This meaſure ſoon proved fatal to Mr. Addington's adminiſtration, and the reins of government having dropped from his hands, were immediately ſeized by Mr. Pitt. Mr. Fox now joined lord Grenville, and it was ſuppoſed an extended adminiſtration would have been formed, in which theſe gentlemen and their friends would have made a part. While however Mr. Pitt expreſſed his readineſs, and even his anxious wiſh to comply with what was ſuppoſed the deſire of the country, he, at the ſame time, hinted that inſurmountable obſtacles had occurred in a *certain quarter*. Scarcely had the diſcuſſions on this ſubject ſubſided, when Mr. Pitt, who had long been ill, ſickened and died. A vote of parliament for a public funeral, and the payment of his debts at the expence of the nation, added to his ſudden fate, and univerſally acknowledged talents, all tended to render his memory reſpected. His aſſociates, after a ſhort trial, gave way for the introduction of Mr. Fox once more into office. He re-

ſumed his ſituation as ſecretary of ſtate for the foreign department which he had ſurrendered twenty-two years before. It could not be his wiſh, at this period of his life, to embark on ſo hazardous a voyage, yet at the call of his ſovereign and his country he was willing to ſpend the remains of life in their ſervice. Aware that he had but a ſhort ſpace before him, he declared he ſhould die contented and happy if he could but previouſly obtain peace, an honourable peace for Britain; remove all legal diſabilities ariſing out of religion in order to unite more cloſely the intereſts of Ireland with thoſe of England; and laſtly, obtain a complete abolition of the ſlave trade. Every eye was now directed towards him, and every mind anticipated the good effects of the meaſures that they fondly hoped would, by his influence, be adopted. It was, however, a moſt unfortunate circumſtance, that his colleague, lord Grenville, already an auditor of the exchequer, inſiſted on being alſo firſt lord of the treaſury, offices which had heretofore been incompatible. Mr. Fox, to promote the union, ſo deſirable in the cabinet, vindicated their compatibility, but loſt much credit for his good nature, in the country; nor was his ſecond act better reliſhed, *viz.* of inviting the lord chief juſtice of the king's bench to a ſeat in the cabinet; theſe were regarded as unconſtitutional meaſures, and violent clamours were raiſed againſt him, as introducing precedents moſt fatal to the liberties of the country. The preliminaries being now arranged, one of his firſt acts was a meaſure for the reſtriction of the ſlave trade, and by his means a ſolemn reſolution was voted by the ſenate, and carried up to the ſovereign, on the juſtice and policy, the duty and neceſſity, of the total abolition of this abominable traffic. He declared, in one of the debates on this buſineſs, on behalf of himſelf and ſuch of his colleagues as had voted with him on the ſubject when out of office, that they felt the total abolition of the ſlave trade as a ſtep involving the deareſt intereſts of humanity, and as one which, however unfortunate they might be in other reſpects, ſhould they be ſucceſsful in effecting it, would entail more true glory upon their adminiſtration, and more honour upon their country, than any other tranſaction in which they could be engaged. Scarcely had he commenced his career of public and official buſineſs, in which his country and the world would have been benefitted, before the powers of his body ſunk exhauſted by the too vigorous exertions of his mind; and the immenſe preſſure of public concerns broke down a conſtitution which had previouſly indicated ſymptoms of decay, and in a few months deprived his country of the moſt enlightened and patriotic ſtateſman which this, or any other nation could boaſt, before the mighty ſchemes revolving in his breaſt could be matured and developed, and almoſt before any one of his wiſe and ſalutary plans could be carried into effect. Had he lived but a year, or even a few months longer, he might probably have reſtored peace to a diſtracted world; he might, had he not been thwarted and oppoſed by his colleagues, ſome of whom could not poſſibly enter into his feelings, nor comprehend the grand motives of his actions, have reſtored the conſtitution of Britain to its ancient ſplendour, by an annihilation of the diſgraceful traffic in the repreſentation, and by expunging from the ſtatute book thoſe modern acts which diſfigure and diſgrace it. He died Sept. 13, 1806, without pain and almoſt without a ſtruggle, in the 58th year of his age. It happened to few men, if to any, to leave ſo many ſorrowing friends; his deceaſe was the ſubject of univerſal lamentation, and the general regret which took place when the event was announced, and which followed him to his grave by the myriads who aſſembled to teſtify their reſpect to his memory, ſpoke more powerfully of the merits and claims of Mr. Fox than language could deſcribe. Nevertheleſs the pulpit and preſs were made uſe of by the clergy of all denominations, and by perſons of different, and even oppoſite political parties, to illuſtrate his virtues and celebrate his well earned fame. Many of the characters drawn of this great man have been collected in a volume by one of the moſt learned men of the age, who aſſumes the title of "Philopatris Varvicenſis." Of this work we have already made much uſe in the courſe of the foregoing article, and to ſeveral parts of it we ſhall be ſtill more indebted for the following delineation of Mr. Fox's character.

"To an extraordinary natural capacity, improved and embelliſhed by a liberal education, and to a quickneſs of apprehenſion which inſtantly ſeized every object that was preſented to it, and which with incredible facility developed the moſt intricate problems, this great man added a memory richly ſtored with the treaſures of ſcience and literature, and well fraught with hiſtorical and political knowledge. He was profoundly verſed in the hiſtory and the conſtitution of his country. He perfectly underſtood its external relations, its connection with foreign powers, its political and commercial intereſts, its financial reſources, its military and naval ſtrength. He was well acquainted with the hiſtory, the ſtrength, the policy, the ſeparate and relative intereſts and views of thoſe ſtates which once conſtituted what has not been improperly called the great republic of Europe; and upon the juſt equipoiſe of the political power and influence of which the liberty, ſafety, and proſperity of the whole was ſuppoſed to depend. And, in a word, he was ignorant of nothing which was neceſſary to conſtitute the conſummate ſtateſman. To this was added an extent of views, a comprehenſion of mind, and an energy of character peculiarly his own. All theſe were combined with a philanthropy, which originated in a natural goodneſs of heart, improved and extended by hiſtorical knowledge, and perſonal obſervation, of the ineſtimable bleſſings which reſult from civil liberty, and from a wiſe adminiſtration of government, and of the miſeries which accrue to mankind from unjuſt wars, from tyranny and perſecution; and confirmed by generous exertions in defence of the injured, inſulted, and oppreſſed: ſo that what was originally nothing more than a natural bias of the mind, became by degrees a moral principle, and grew up into a fixed habit of univerſal, active, and diſintereſted benevolence. His eloquence, that divine eloquence, which aſtoniſhed and captivated the world, conſiſted, not in pomp of diction nor in melody of ſound; not merely in a happy ſelection of expreſſions, though the beſt and the moſt appropriate which the language could ſupply ſpontaneouſly offered themſelves to his uſe; not in dazzling the fancy with brilliant imagery; not in bewildering the underſtanding with plauſible ſophiſtry; not in flattering the prejudice of his hearers, nor in exciting falſe hopes or groundleſs terrors to render them blindly ſubſervient to party purpoſes:—to ſuch unworthy artifices his manly ſpirit diſdained to ſtoop. His eloquence was of a nobler kind. Plain, nervous, energetic, vehement: it ſimplified what was complicate, it unravelled what was entangled, it caſt light upon what was obſcure, and through the underſtanding it forced its way to the heart. It came home to the ſenſe and feelings of the hearer; and by a ſecret, irreſiſtible charm, it extorted the aſſent of thoſe who were moſt unwilling to be convinced. And to crown all, this aſtoniſhing eloquence was uniformly exerted in the cauſe of liberty and juſtice, in defence of the oppreſſed and perſecuted, and in vindicating the rights, the freedom, and the happineſs of mankind.

"Never,

"Never, during the whole of his long parliamentary life, was his voice lifted up to juſtify oppreſſion or perſecution: never did the injured or oppreſſed appeal to the Britiſh ſenate, that he did not exert his noble eloquence on their behalf. He made the cauſe of all that were wronged his own; and, even where he failed, through the perverſeneſs of the times, of procuring juſtice for them, he in a meaſure compenſated their ſufferings, by lending his great talents to their cauſe, and by drawing towards it the ſympathy of mankind. In him, the moſt diſcordant ſects, and the moſt diſtant provinces, found an ever ready defender and a generous patron. He pleaded (and with what ſtrength of argument, what rich variety of illuſtration, what dignity of ſentiment, what majeſty of diction!) for the equitable privileges of the Roman Catholic and the Proteſtant diſſenter; and he contended, with an eloquence alternately indignant and pathetic, for the rights of the haraſſed Iriſh, the oppreſſed Hindoos, and the ſuffering Africans.

"The various opinions which Mr. Fox delivered, during the long courſe and diverſified conflicts of his public life, contain a treaſure of political philoſophy, which no ſtateſman can ſtudy without becoming more benevolent and more wiſe. The notions which he uttered were not taken up at random, and again laid down without conſideration, as intereſt or paſſion might impel. Such may be, and ſuch are, the fluctuations of thoſe who venture on the ſea of politics, without ſagacity to direct their way, or honeſty to keep them ſteady in their courſe. The axioms which Mr. Fox embraced as the pole-ſtar of his political conduct, and which he inculcated as the beſt means of promoting the happineſs of nations, were deduced from a profound and comprehenſive ſurvey of human affairs, from an intimate acquaintance with human nature, and from an enlightened view of the end for which government was eſtabliſhed. His political ſentiments, originating in principles which are as immutable as the attributes of the deity, from which they are derived, were not ſubject to any vicious defection or capricious fluctuations. Though Mr. Fox was no formal religioniſt, yet the eſſence of religion, which centres in charity, was the predominant ſenſation of his heart. If religion conſiſt in doing to others as we would that they ſhould do to us; if it have any connection with a holy endeavour to preſerve peace on earth, and good will among men, (and what Chriſtian will deny this?) then we will venture to ſay, that Mr. Fox, who never made any ſhew of religion, was, in fact, one of the moſt religious men of the age. The great object of his political life was to prevent the havock of war, and to preſerve the world in peace. His exertions were indeed ineffectual, but they were unintermitted; and if he who ſaves the life of one man deſerves a civic crown, what recompence muſt be due to him who laboured, with ſo much conſtancy and zeal, to reſcue millions from an untimely grave? If peace, ſince the commencement of the Chriſtian era, ever had a ſteady, a diſintereſted advocate, it was in Mr. Fox. Peace was his conſtant aim, his ardent hope, his living counſel, and his dying prayer."

Mr. Fox muſt now be conſidered as an author. While at Eton, his compoſitions were highly diſtinguiſhed, ſome of which are in print; as one compoſed in or about the year 1761, beginning, "Vocat ultimus labor;" another, "I, fugias, celeri volitans per nubila curſu," written in 1764; and his "Quid miri faciat Natura," which was followed by a Greek dialogue in 1765. See Muſæ Etonenſes, &c.

Mr. Fox is author of the 14th, 16th, and perhaps, ſays the preſent lord Holland, his nephew, a few other numbers of a periodical publication in 1779, called the Engliſhman.

In 1793, he publiſhed "A Letter to the Electors of Weſtminſter," which paſſed through thirteen editions within a few months. This pamphlet contains a full and ample juſtification of his political conduct, with reſpect to the diſcuſſions in which he had engaged on the French revolution.

It does not appear that the parliamentary ſpeeches, printed ſeparately as his, of which there are many, were ever reviſed by him, but were taken from the public papers. But "A Sketch of the Character of the late moſt noble Francis Duke of Bedford, as delivered in his introductory Speech to a Motion for a new Writ for Taviſtock, on the 16th of March, 1802," was printed by his authority, and from his own manuſcript copy; and it is ſaid, that he obſerved on that occaſion, "that he had never before attempted to make a copy of any ſpeech which he had delivered in public." Since this, he wrote an epitaph on the late biſhop of Downe, which is engraved on his tomb, in the church of St. James, in the Hampſtead road. "There are," ſays lord Holland, "ſeveral ſpecimens of his compoſition in verſe, in different languages; but the lines on Mrs. Crewe, and thoſe on Mrs. Fox, on his birth-day, are, as far as I recollect, all that have been printed." An ode to Poverty, and an epigram upon Gibbon, though very generally attributed to him, are certainly not his compoſitions.

To lord Holland, however, the world is indebted for an important and ſingularly valuable poſthumous publication of this great ſtateſman, entitled, "A Hiſtory of the early Part of the Reign of James the Second, with an introductory Chapter," &c. It is not known when he firſt formed the deſign of writing a hiſtory; but in the year 1797, he publicly announced in parliament his intention of devoting a greater portion of his time to his private purſuits: "After ſeeing," ſays he, "the conduct of this houſe, after ſeeing them give to miniſters their confidence and ſupport, upon convicted failure, impoſition, and incapacity; after ſeeing them deaf and blind to the conſequences of a career that penetrates the hearts of all other men with alarm; and that neither reaſon, nor experience, nor duty, are ſufficiently powerful to influence them to oppoſe the conduct of government, I certainly do think that I may devote more of my time to private purſuits, and to retirement which I love, than I have hitherto done." When he had determined to conſecrate a part of that time in writing hiſtory, he was naturally led, from his intimate knowledge of the Engliſh conſtitution, to prefer the hiſtory of his own country, and to ſelect a period favourable to the general illuſtration of the great principles of freedom on which it is founded. With this view, he fixed on the revolution of 1688, as being the moſt ſignal triumph of that cauſe to which his public life had been devoted; and alſo, with the deſire of reſcuing from miſrepreſentation the moſt glorious tranſaction of our hiſtory; of inſtructing his countrymen in the real nature of their conſtitution, and of impreſſing on mankind thoſe leſſons applicable to all times, which are to be drawn from that memorable occurrence. It is to be lamented that the author had made ſo little progreſs in this work, when he was called to take a principal part in the government of the country. The volume comprehends only the hiſtory of the tranſactions of the firſt year of the reign of James II., with an introductory chapter on the character and leading events of the times immediately preceding. Short, however, as this fragment is, yet the advantages reſulting from it are numerous and important. It contains a picture, drawn with a maſterly hand, of the practical tyranny that was exerciſed over this nation, under

the

the reigns of Charles II. and James II.; which ſhews, that had affairs proceeded, for a ſhort time only, in the ſame courſe, the forlorn and deſolate aſpect of deſpotiſm muſt have been permanently impreſſed upon the country: it likewiſe exhibits a mournful picture of that ſervile ſubmiſſion, which then ſeemed to form the character of the nation, and to point them out as the willing victims of oppreſſion: and it ſtigmatizes thoſe time-ſerving and bigotted hiſtorians, who have endeavoured to diſguiſe the enormities of that period; to write the apology of venality and deſpotiſm; to repreſs the virtuous emotions of hatred and indignation, which the ſcenes then paſſing are calculated to excite; and who have contributed ſo largely to corrupt the moral ſentiments of our people, and extinguiſh among us the love of our country, and a diſintereſted courage in public affairs. Engliſh Peerage. Parliamentary Debates. Hiſtory of the early Part of the Reign of James II., &c. &c.

Fox de Morzillo, Sebastian, a Spaniſh philoſopher and man of letters, was born at Seville in 1528, and purſued his ſtudies partly in his own country and partly in the Netherlands. He began to attract the notice of the learned world by his literary productions ſoon after he was twenty years of age; and in a ſhort time acquired ſo high a reputation, that Philip III. fixed upon him as a fit perſon for the office of preceptor to the Infant Don Carlos. When he was nominated to this high charge, he was a reſident at Louvain; but, on its being notified to him, he inſtantly prepared to return to Spain by ſea. The ſhip in which he embarked was unfortunately wrecked, and he periſhed in the morning of life. The principal works which he left behind him were, "De Studii Philoſophici Ratione;" "De Uſu et Exercitatione Dialecti;" "De Honore;" "De Juventute;" "De Regno et Regis Inſtitutione Lib. iii." Moreri.

Fox, in *Engineery*, ſometimes ſignifies a heading, or ſough underground. See Smeaton's Reports, i. 48.

Fox, in *Geography*, a town of Peru; 9 miles E. of Lopes.

Fox *Iſland*, an iſland near the weſt coaſt of Ireland; 7 miles E. of Slyne head.—Alſo, an American iſland, near the coaſt of Main. N. lat. 44° 2′. W. long. 68° 40′.

Fox *Iſlands*, a group of iſlands between Kamtſkatka and America, forming a part of the chain called the *Aleutian* iſlands, which ſee. Theſe conſtitute, according to the arrangement of Mr. Muller, the fourth claſs of iſlands lying between Kamtſkatka and America; the other three claſſes being the *Saſignes*, comprehending ſix iſlands, *viz.* Behring's and Copper iſlands, and the neareſt Aleutians, of which Otma, Semia, and Anatto are moſt eminent; and *Chao*, comprehending eight iſlands, *viz* Immak, Kiſka, Tſhetgina, Ava, Chavia, Tſhagulak, Ulagabma, and Amtſhigda, or the more diſtant Aleutians; and *Negho*, containing what are called the Andreanofskiye iſlands, ſuch as the ſixteen following, *viz.* Amatkineg, Ulek, Unalga, Navotſha, Uliga, Anægin, Chagulak, Illaſhe, Tekavanga, Kanaga, (which two are remarkable for burning mountains,) Lek, Shetſhuna, Tagalukos, behind which follow ſome uninhabited little rocks and iſlands, one of which, on account of its black cliffs, is called by the Ruſſians Goreloi (the burnt), and laſtly, Atſhak and Amlak. The fourth claſs, or Fox iſlands, called *Kavalang*, comprehend the following ſixteen; *viz.* Amukta, Tſhigama, Tſhagula, Uniſka, Ulaga, Tanagulæna, Kagamin, Kigalga, Shalmaga, Unmak, Agua-Alæſka or Unalaſhka, Unimga or Unimak, toward which a point of land from the continent of America, with a few circumjacent iſlands, is ſaid to project; and beyond this point are Uligan, Autun-Duſſuma, Semedit, and Senegak, whence perhaps Kadiak was formed. The Andreanofskiye and Fox iſlands are in general as mountainous as the Aleutian and Behring's iſland. Their coaſts are rocky, and ſurrounded by breakers. The land riſes immediately from the coaſts to ſteep, bold, rock-mountains, gradually aſcending higher behind each other, and aſſuming the appearance of chains of mountains, with a direction lengthwiſe of the iſland, and having, commonly in the midway of the breadth, the higheſt ridges. Springs riſe at the foot of the mountains, and either flow in broad and rapid ſtreams into the neighbouring ſea; or collecting themſelves in the rocky vales and glens beneath, form ample lakes, which let off their ſuperfluous waters by natural canals into the adjacent bays. Several of theſe iſlands, where at preſent no ſmoking volcano is any longer diſcernible, as Ayak and Tſhetekina, ſeem anciently to have had them, as their traces are ſtill to be ſeen in the ſulphureous boiling ſources that are met with at various intervals. On Tatavanga and Kanaga, among the Andreanofskiye iſlands, and again on Umnak, on the great iſland Unalaſhka, and on Unimga, among the Fox iſlands, are ſtill active volcanoes, which continually emit ſmoke, and from ſome of them frequently iſſue flames. No traces of metals have ever yet been deſcried on theſe volcanic iſlands. But carneoles and ſardonyxes are brought from them. The ſoil of theſe iſlands is ſaid to reſemble that of Kamtſkatka; the ſame kinds of edible wild berries and roots have been found there, excepting ſome few vegetables which ſeem to be of foreign produce. Beſides creeping twigs of willow, larches, alders, and birch, which ſeem as little as on the ſnow mountains, no wood has been perceived on theſe iſlands, Radiak excepted. On Unalaſhka, however, in ſome deep holes, a ſmall quantity of wood ſhoots up. But the ſea wafts all ſorts of floating timber to their ſhores. On the Fox iſlands they have an extraordinary number of foxes, black and grey, as well as red and brown. Here are alſo bears, wolves, river-otters, river-beavers, martins, and ermines, which ſeem to have come over from America. The ſea-otter is frequently caught here. Their ſeas abound in all ſorts of ſeals, dolphins, and whales; ſea-lions and porpoiſes are rare, and ſea-cows not at all to be ſeen. The water-fowl or fiſh are the ſame as at Kamtſkatka. The winter is tolerably mild, but the ſummer equally ſhort and unpleaſant. Theſe iſlands are pretty well peopled; the inhabitants moſtly pay tribute to Ruſſia, and drive a bartering trade with the Ruſſian mariners, who go thither on account of the very profitable chace of ſea-otters and foxes. They are, however, not always to be truſted, as no ſmall number of Ruſſians have experienced to their coſt, having been robbed and murdered by theſe ſavages. Tooke's Ruſſ. Emp. vol. i.

Fox *Iſlands*, are alſo a ſmall cluſter of ſmall iſlands on the ſouth ſide of the gulf of St. Lawrence. N. lat. 51°. W. long. 59° 10′.

Fox *River*, a river of Canada, which runs into the gulf of St. Lawrence; 9 miles N.N.W. of Cape Roſieres.—Alſo, a river of North America, which forms a communication between Green bay in lake Michigan, and lake Winnebago. For four or five miles from the bay the river has a gentle current; then, till you arrive at the Winnebago lake, it is full of rocks and very rapid, ſo that it is neceſſary at many places to land the canoes, and carry them for a conſiderable interval. Its general breadth from the Green lake to Winnebago lake is between 70 and 100 yards; the land on its borders is very good, and thinly wooded with hickery, oak, and hazel. The Attigaumies and Saulies once inhabited the banks of this river. The mouth lies W. long 87° 53′. N. lat. 43° 48′.—Alſo, a river of Canada, which

runs

runs into lake Michigan. N. lat. 48° 30'. W. long. 87° 20'.—Alſo, a river of the weſtern territory of America, which runs into the Theakiki. N. lat. 41° 28'. W. long. 87° 58'.—Alſo, a river of the weſtern territory of America, which runs into the Wabaſh. N. lat. 38°. W. long. 88° 33'.

Fox's *Tram-road*, in Glamorganſhire, is one of the numerous ſeparate eſtabliſhments for improved communication which have ariſen of late years in South Wales. Of this tram road we were uninformed at the time of compiling the general alphabetical account of ſuch eſtabliſhments affixed to our article CANAL; it commences in Neath river, at Neath town, and croſſing the public bridge by the ſide of the carriage way, (a ſingular inſtance,) proceeds one mile to Neath Abbey iron furnace, to the foot of the ſteep plane for horſes, 200 yards long and 70 feet riſe, which aſcends to the bridge-loft, whence the furnace is charged with ore, coak, and lime-ſtone.

Fox, in *Sea Language*, ſignifies a ſort of ſtrand, formed by twiſting ſeveral rope-yarns together, and uſed as a ſeizing, or to weave a mat or paunch, &c.

Fox, *Vulpes*, in *Zoology*, an animal of the dog-kind; much reſembling the common dog in form, and of the ſize of the ſpaniel. It is chiefly diſtinguiſhed by its long, ſtraight tail, with a white tip to it. See VULPES.

It differs, however, from the common dog in the length, denſe diſpoſition, and ſoftneſs of the hairs, eſpecially thoſe about its tail, which is buſhy, much admired by the animal itſelf, and in cold weather wrapped round its noſe; and in its ſmell, which is peculiarly rank and diſagreeable. The ſmell of its urine is remarkably fœtid; inſomuch that the animal covers it in the earth. It is ſaid that the fox makes uſe of its urine as an expedient to force the cleanly badger from its habitation; however, it makes uſe of the badger's hole. Its uſual colour is a reddiſh tawny, though it is ſometimes found white, and ſometimes black. Its fore-feet and tops of the ears are black; the ears are erect, and the lips are white. Its manner of digging itſelf a hole in the earth is alſo a cuſtom wholly different from that of all the dog-kind; and it is far from the tameneſs of that animal, being with difficulty made to loſe its fierceneſs. Of all animals the fox has the moſt ſignificant eye, by which it expreſſes every paſſion of love, fear, hatred, &c.

The fox is a crafty, lively, libidinous animal; it breeds only once a year, unleſs ſome accident befalls its firſt litter, and brings four or five young, which, like puppies, are born blind.

The fox is the Αλοπηξ of Ariſtotle and Ælian, and the Κεῤῥω of Oppian. It inhabits Europe, Aſia, Africa, and America, as far as Chili, and accordingly is a native of moſt northern countries; and there are three varieties of it, differing a little in form but not in colour. They are diſtinguiſhed in Wales by different names. The greyhound fox is the largeſt, talleſt, and boldeſt, and will attack a grown ſheep or wether: the maſtiff fox is leſs, but more ſtrongly built; the cur fox is the leaſt, lurks about hedges, outhouſes, &c. and is the moſt pernicious to the feathered tribe. The firſt of theſe has a white tip to the tail; the laſt a black. The ſkin of this animal is furniſhed with a ſoft and warm fur, which in many parts of Europe is uſed to make muffs and fine cloths.

A fox in the firſt year is called a cub; in the ſecond a fox, and afterwards an old fox. It is a beaſt of chace, uſually very prejudicial to the huſbandman, by taking away and deſtroying his lambs, geeſe, and poultry. It will feed on fleſh of any kind; and, when urged by hunger, eat carrots and inſects, and the dung of other animals; and, near the ſea-coaſts, for want of other food, eat crabs, ſhrimps, or ſhell fiſh. In France and Italy it does incredible damage in the vineyards, by eating the grapes, of which it is very fond, and which make it fat; ſo that at this time its fleſh is reckoned good food. The fox is a great deſtroyer of rats and field animals. It ſecures its booty by digging holes in ſeveral places; and if a whole ſtock of poultry ſhould happen to be its prey, will bring them one by one, thruſt them in with its noſe, and conceal them by ramming the looſe earth upon them, till the calls of hunger induce him to devour them. It does not readily commit thefts in the neighbourhood of its own haunts. It is much terrified by fire-arms, flies from the ſmell of gunpowder, and may be chaſed away by means of ſmoke. The common way to catch him is by gins, which being baited, and a train made by drawing raw fleſh acroſs his uſual paths or haunts to the gin, it proves an inducement to allure him to the place of deſtruction. They are alſo taken with greyhounds, hounds, terriers, and nets; it is a commendable exerciſe to hunt theſe miſchievous beaſts, the nature of which, in many reſpects, is like that of wolves. See HUNTING.

Fox, *Antarctic*, *C. Vulpes Auſtralis*, Coyotl, or Indian fox, Fernand. Mex. Wolf-fox, Bougainville, has the tail pendent, buſhy, and tipt with white, the ears ſhort, erect, and pointed. This animal inhabits America and Falkland iſlands. It is about a third larger than the common fox, and has the habits of the wolf in the ears, tail, and ſtrength of limbs. In Falkland's iſlands it lives near the ſhore, kennels like foxes, and has regular paths from one part of the ſhore to another for ſurpriſing the ſea-fowl, on which it chiefly feeds. It is very tame, barks like a dog, and has a very fœtid ſmell; the head and body are covered with woolly hair of a cinereous brown colour; the legs are daſhed with ruſt-colour. The tail is duſky; and the inſides of the ears are lined with white hair.

Fox, *Arctic*. See LAGOPUS.

Fox, *Black*, *C. Vulpes Lycaon*, reſembles the wolf, and is of an intermediate ſize between that animal and the fox. It has a ſtraight tail, and the body is wholly black; ſometimes variegated with greyiſh, or having the tips of the hairs of a ſilvery whiteneſs. It inhabits the coldeſt regions of Europe, Aſia, and America; and is reckoned the moſt cunning animal of the genus. Its fur is deemed very valuable, being preferred in Ruſſia to the fineſt ſables, one ſkin ſometimes ſelling for two roubles. Thoſe of America are of inferior beauty.

Fox, *Brant*. See ALOPEX.

Fox, *Coal*. See ALOPEX.

Fox, *Corſac*, *C. Vulpes Corſac*, is diſtinguiſhed by its ſtraight, tawny tail, which is black at the root and tip. This ſpecies or variety is leſs than the common fox, but in other reſpects is very ſimilar to it. It is greedy of birds, has a bad ſmell, and howls and barks like thoſe of the common kind; the ears are upright, the hair is ſoft and downy; the tail is buſhy, and as long as the body; the fur is of a pale tawny colour in ſummer, growing grey in winter, with a white throat; the tail is cinereous, except the baſe and tip. It chiefly inhabits the great deſert between the Ural and the Irtiſh, in Aſiatic Ruſſia. Forty or fifty thouſand of the ſkins of this animal are annually ſold by the Kirghis Coſſacks to the Ruſſians, being caught by means of falcons and greyhounds.

Fox, *Croſs*, *C. Vulpes Crucigera*, has a black croſs on the ſhoulder; the fur is thicker and ſofter than that of the common fox, and is reckoned valuable. It inhabits the coldeſt parts of Europe, Aſia, and North America.

Fox,

Fox, *Desert*, or *Karagan*, has a ſtraight tail, with the body of a grey colour, and black ears. It inhabits the deſerts belonging to the Kalmucks and Kirgiſes.

Fox-*hound*. See Dog and Hound.

Fox, *Siberian*. See Lagopus.

Fox, *Silvery*, *C. Vulpes cinereo-argenteus*, has a ſtraight tail, the body of a ſilver-grey colour, and the ſides of the neck of a yellowiſh brown. This animal is ſmaller than the common fox, but agrees with it in figure and manners. It inhabits North America.

Fox, *Grey*, *C. Vulpes Virginianus*, has a ſtraight tail, and the body of a whitiſh-aſh colour. This ſpecies inhabits Carolina, lives in the hollow trunks of decayed trees, and is eaſily tamed.

Fox, *Sea*, *Vulpes marina*, in *Ichthyology*, the name given by authors to a large fiſh, called the *ſea-fox* by us. In the Artedian ſyſtem it is the ſqualus, with a tail longer than the body. See Squalus *Vulpes*.

Fox-*glove*, in *Botany*, the common name of a large well-known plant. See Digitalis.

Fox-*tail Graſs*, the common name of a valuable ſort of natural meadow graſs. See Alopecurus and Grass.

FOXBOROUGH, in *Geography*, a townſhip of America, in Norfolk county, and ſtate of Maſſachuſets; 26 miles S. of Boſton: incorporated in 1778, and containing 779 inhabitants.

FOXERNA, a town of Sweden, in Weſt Gothland; 24 miles N. of Gothenburg.

FOXFORD, a ſmall poſt town of the county of Mayo, Ireland, ſituated on the river Moy, and about two miles from Lough Conn. It is 113 miles W. by N. from Dublin, and eleven from Caſtlebar, on the road to Sligo.

FOXTOWN, a town of America, in the ſtate of North Carolina: 30 miles S. of Newbern.—Alſo, a town of the ſtate of New York; 24 miles W. of New York.

FOY-LA-GRANDE, Sainte, a town of France, in the department of the Gironde, and chief place of a canton in the diſtrict of Libourne. The place contains 2,830, and the canton 11,068 inhabitants, on a territory of 145 kiliometres, in 17 communes.

FOYERS, or Fyers, a ſmall river of Inverneſsſhire, which takes its riſe among the mountains of Abertarff, running in a northerly direction through the valley of Foyers, and emptying itſelf into Loch Neſs, about the midway between its eaſtern and weſtern extremity, is remarkable for a ſtupendous waterfall. In as deep and romantic a glen as perhaps can be imagined, the Foyers pours its waters between lofty mountains, covered with penſile birch trees, exhibiting their naked, abrupt, and broken fronts, from which huge fragments have been detached. The torrent, confined on the rocky ſides, precipitates itſelf with great velocity into the profound beneath, forming a notable cataract. A little below, a bridge has been thrown acroſs the river, whence a ſight of the fall may be obtained; but the moſt advantageous poſition for viewing the object in all its beauty and grandeur, is at the foot of the rocks beneath. Theſe, with the expanſive arch of the bridge, exhibit a fine pictureſque fore-ground, behind which, at the diſtance of about twenty yards, appears the firſt portion of the fall; the central and largeſt break is a few yards nearer, and the third is over a ledge, almoſt under the arch. From accurate meaſurements taken of this, which is called the Upper Fall, the diſtance from the crown of the arch to the ſurface of the water, after the fall, is 200 feet, and of the fall itſelf, 100. Half a mile lower down, the river ruſhes over another ledge, with a noiſe like thunder, into the abyſs below, forming one unbroken ſheet of ſtream as white as ſnow, foaming and raging over the looſe fragments of rock, which retard its impetuous courſe. From the violent agitation ariſes ſo thick a ſpray, as to completely envelope the ſpectator. The ſcenery and effect of this are beautifully and accurately pourtrayed by a real child of nature, the eccentric Burns.

"Among the heathy hills and ragged woods,
The roaring Fyers pours his maſſy floods;
Till full he daſhes on the rocky mounds,
Where through a ſhapeleſs beach his ſtream reſounds.
As high in air the burſting torrents flow,
As deep recoiling ſurges foam below,
Prone down the rock the whitening ſheet deſcends,
And viewleſs echo's ear, aſtoniſhed lends.
Dim ſeen, through riſing miſts and careleſs ſhowers,
The hoary cavern, wide ſurrounding low'rs.
Still through the gap the ſtruggling river toils,
And ſtill below the horrid cauldron boils."

"This," Dr. Garnet obſerves, from whoſe Tour the account has been extracted, "is undoubtedly one of the higheſt falls in the world; and though the immenſe body of water which falls down the celebrated caſcade of Niagara in North America gives a ſuperiority to that, yet it muſt yield to this in point of height; the former fall being 140 feet, and the latter 212.

FOYLE, a river of Ireland, formed by the confluence of the rivers Derg and Fin near Lifford. It paſſes the city of Derry, and four miles below it expands into Lough Foyle. It is navigable by large veſſels to the quay of Derry, and for lighters which carry twenty tons, to Lifford.

Foyle-*Lough*, a large bay, or eſtuary, in the north of Ireland, formed by the expanſion of the waters of the river Foyle, and ſeveral ſmaller ſtreams which run into it. It is twelve miles long, and about ſeven broad, and is land-locked on all ſides, the entrance being only half a mile wide. There is a channel in the middle, which is fourteen fathoms at low water, and ten fathoms at the entrance; but on account of its extreme narrowneſs it is difficult to tack up, when the wind blows down the river. Veſſels turning in with a ſouth-weſterly or weſterly wind alſo run ſome hazard of being ſtranded on the beach of Magilligan. This circumſtance is very unfavourable to the trade of Derry.

FOYLING *of Land*, in *Agriculture*, a term ſometimes made uſe of by old farmers for naked or ſummer fallowing; but which at preſent is ſeldom employed.

Foyling, among *Sportſmen*, a term uſed for the footſteps of a ſtag, on the graſs or leaves.

FOYNA, in *Zoology*, a name given by many to the martin or martes, an animal of the weaſel kind, common with us. See Mustela.

FOZ, in *Geography*, a town of Portugal, in the province of Alentejo, at the conflux of the Zatas and Tagus; 24 miles N. E. of Liſbon.

FOZZANO, a town of the iſland of Corſica; four miles N. of Sarſano.

FRACASTORIUS, Hieronimus, in *Biography*, a celebrated phyſician of Verona, where he was born in 1483. He ſeemed to be born for ſtudy; for ſuch was the ardour with which he applied, and the rapidity with which he advanced in the ſtudy of the languages, the belles lettres, and the ſciences, that he early attained a high degree of excellence as a poet, a philoſopher, an aſtronomer, and a phyſician. Theſe qualities procured him an univerſal eſteem. The general of the Venetian forces gave him his entire con-

fidence, and Fracaſtorius followed him as his phyſician, during many campaigns, and quitted him only at the period of his death, in 1515, when he returned to his native place. It was upon the repreſentations of Fracaſtorius that the fathers, aſſembled at Trent, were induced to transfer the council to Bologna, in order to avoid the contagious epidemic which prevailed at the firſt mentioned place. He maintained a literary correſpondence with moſt of the great men of his age, eſpecially with cardinal Bembo, who was his intimate friend, and to whom he dedicated his elegant poem, entitled "Syphilis," *i. e.* the venereal diſeaſe. This poem was highly admired by Bembo, Sannazarius, and other men of taſte, and was compared with the Georgics of Virgil, for its rich and melodious verſification, its vivid imagery, and its noble ſentiments. Fracaſtorius retired towards the cloſe of his life to a country-houſe near Verona, ſituated at the foot of mount Baldo, where he applied to the ſtudy of aſtrology and coſmography, and died of apoplexy on the 6th of Auguſt, 1553, at the age of 71 years.

All the works of Fracaſtorius have been printed under the title of "Opera omnia Philoſophica et Medica," at Venice, Lyons, &c. His works conſiſt of, 1. "Syphilidis, ſive de Morbo Gallico, Libri tres," firſt publiſhed at Verona in 1530, and afterwards frequently republiſhed, and alſo tranſlated into the Italian and French languages: 2. "Homocentricorum, ſive de Stellis, Liber unus," Venice, 1538, with the following, 3. "Libellus de cauſis dierum criticorum:" 4. "De Sympathia et Antipathia, Liber:" 5. "De Contagionibus, et Contagioſis Morbis, et eorum curatione, Libri tres:" 6. "Naugerius, ſive de Poëtica Dialogus:" 7. "Turrius, ſive de Intellectione Dialogus:" 8. "Fracaſtorius, ſive de Anima Dialogus:" 9. "De Vini Temperatura:" 10. "Joſephi Libri duo:" 11. "Carminum Liber unus:" 12. "Alcon, ſive de cura canum venaticarum."

The town of Verona, which had formerly erected honourable monuments to the memory of Catullus and of Pliny, reſolved to confer the ſame diſtinguiſhing honour on Fracaſtorius; and a ſtatue was acordingly erected to this phyſician, in 1559, "Ex publica Authoritate."

FRACHES, in the *Glaſs Trade*, are flat iron pans, into which the glaſs veſſels already formed are put, when in the tower over the working furnace, and by means of which they are drawn out through the leers, that they may be taken gradually from the fire, and cool by degrees.

FRACTION, in *Arithmetic* and *Algebra*, a part or diviſion of an unit, or integer; or, a number which ſtands to an unit in the relation of a part to its whole.

The word literally imports a broken number.

Fractions are uſually divided into *decimal*, *ſexageſimal*, and *vulgar*.

For *decimal* and *ſexageſimal* fractions, ſee DECIMAL and SEXAGESIMAL.

FRACTIONS, *Vulgar*, called alſo ſimply *fractions*, are always expreſſed by two numbers, the one placed over the other with a line between them.

The lower, called the *denominator* of the fraction, denotes the unit, or whole, that is divided into parts; and the upper, called the *numerator* of the fraction, expreſſes the parts given in the preſent caſe.

Thus, two third parts of a line, or other thing, are written $\frac{2}{3}$; where the denominator 3 ſhews that the whole line is ſuppoſed to be divided into three equal parts; and the numerator 2 indicates or aſſigns two of ſuch parts.

Again, twenty-nine ſixtieths is written $\frac{29}{60}$; where the numerator 29 expreſſes 29 parts of an integer divided into 60; and the denominator 60 gives the denomination to theſe parts, which are called *ſixtieths*.

The real deſign of adding the denominator, is to ſhew what aliquot part the broken number has in common with unity.

In all fractions, as the numerator is to the denominator, ſo is the fraction itſelf to the whole whereof it is a fraction. Thus, ſuppoſing $\frac{3}{4}$ of a pound equal to 15*s*. it is evident, that 3 : 4 :: 15 : 20. Whence it follows, 1°, That there may be infinite fractions of the ſame value, one with another; inaſmuch as there may be infinite numbers found, which ſhall have the ratio of 3 : 4.

Fractions are either *proper* or *improper*.

FRACTION, *Proper*, is that where the numerator is leſs than the denominator; and, conſequently, the fraction leſs than the whole, or integer, as $\frac{2}{4}\frac{5}{6}$.

FRACTION, *Improper*, is where the numerator is either equal to, or bigger than the denominator, and of courſe the fraction equal to, or greater than the whole, or integer, as $\frac{2}{2}\frac{5}{1}$ or $\frac{2}{2}\frac{7}{0}$; or $\frac{9}{2}\frac{0}{2}$.

Fractions, again, are either *ſimple* or *compound*.

FRACTIONS, *Simple*, are ſuch as conſiſt of only one numerator, and one denominator; as $\frac{2}{7}$, or $\frac{14}{350}$, &c.

FRACTIONS, *Compound*, called alſo *fractions of fractions*, are ſuch as conſiſt of ſeveral numerators and denominators; as $\frac{4}{7}$ of $\frac{11}{12}$ of $\frac{5}{6}$ of $\frac{15}{80}$.

Of fractions, thoſe are equal to each other whoſe numerators have the ſame ratio to their denominators.—Thoſe are greater, whoſe numerators have a greater ratio; and thoſe leſs which have leſs: thus $\frac{3}{6} = \frac{4}{8} = \frac{5}{10} = \frac{25}{50} = \frac{1}{2}$. But $\frac{3}{14}$ is greater than $\frac{2}{6}$; and $\frac{4}{6}$ leſs than $\frac{10}{15}$. Hence if both the numerator and denominator of a fraction, as $\frac{4}{6}$, be multiplied or divided by the ſame number 2; the products in the former caſe, $\frac{8}{12}$, and the quotients in the latter $\frac{2}{3}$, will conſtitute fractions equal to the firſt fraction given.

The arithmetic of fractions conſiſts in the *reduction*, *addition*, *ſubtraction*, and *multiplication* of them.

FRACTIONS, *Reduction of*. 1. *To reduce a given whole number into a fraction of any given denominator*.—Multiply the given integer by the given denominator, the product will be the numerator. Thus we ſhall find $3 = \frac{24}{8}$, and $5 = \frac{40}{8}$, and $7 = \frac{28}{4}$, &c.

If no denominator be given, the number is reduced to a fraction, by writing 1 underneath it, as a denominator. Thus $\frac{2}{1}$, $\frac{4}{1}$, $\frac{35}{1}$.

2. *To reduce a given fraction to a fraction equal to it, that ſhall have a given denominator*.—Multiply the numerator by the given denominator, and divide the product by the former denominator, and the quotient ſet over the given denominator is the fraction required. Let it be propoſed to reduce $\frac{3}{4}$ to an equal fraction with the denominator 8; $8 \times 3 \div 4 = 6$, and $\frac{6}{8} = \frac{3}{4}$.

3. *To reduce a given fraction to its loweſt terms*, *i. e.* to find a fraction equivalent to a given fraction ($\frac{20}{48}$), but expreſſed in leſs numbers; divide both the numerator 20, and denominator 48, by ſome one number, that will divide them both without any remainder, as here by 4. The quotients 5 and 12 make a new fraction $\frac{5}{12}$ equal to $\frac{20}{48}$.

And if the diviſion be performed with the greateſt number that will divide them both, the fraction is reduced to its loweſt terms. See COMMON *Meaſures*.

If it happens that unity is the only common meaſure of the numerator and denominator; then is the fraction incapable of being reduced any lower: and numbers whoſe greateſt common meaſure is unit, are ſaid to be *prime* to each other.

4. *To*

4. *To reduce two or more fractions to the ſame denomination*; that is, to find fractions equal to the given ones, and with the ſame denominator. Multiply each numerator, ſeparately taken, into all the denominators but its own, and the products ſhall give the new numerators. Then multiply all the denominators into one another, and the product will be the common denominator. Thus, $\frac{2}{3}$ and $\frac{4}{5}$ are $\frac{10}{15}$, and $\frac{12}{15}$, and $\frac{2}{3}$, $\frac{3}{4}$ and $\frac{4}{5}$ are reſpectively $\frac{40}{60}$, $\frac{45}{60}$, and $\frac{48}{60}$.

5. *To find the value of a fraction, in the known parts of its integer.*—Suppoſe, *e. gr.* it were required to know what is $\frac{9}{16}$ of a pound; multiply the numerator 9 by 20, the number of known parts in a pound, and divide the product by the denominator 16, the quotient gives 11*s.* Then multiply the remainder 4 by 12, the number of known parts in the next inferior denomination; and dividing the product by 16, as before, the quotient is 3*d.* So that $\frac{9}{16}$ of a pound = 11*s.* 3*d.*

6. *To reduce a mixed number, i. e. a number partly integral and partly fractional,* as $4\frac{11}{12}$ *into an improper fraction of the ſame value.*—Multiply the integer 4 by 12, the denominator of the fraction; and to the product 48 add the numerator; the ſum 59 ſet over the former denominator, $\frac{59}{12}$, conſtitutes the fraction.

7. *To reduce an improper fraction into its equivalent mixed number.*—Suppoſe the given fraction $\frac{59}{12}$; divide the numerator by the denominator; the quotient is the integral part, and the remainder ſet over the denominator will be the fractional part. Thus $\frac{59}{12} = 4\frac{11}{12}$.

8. *To reduce a compound fraction into a ſimple one.*—Multiply all the numerators into each other for a new numerator; and all the denominators for a new denominator. Thus, $\frac{1}{2}$ of $\frac{3}{4}$ of $\frac{5}{6}$ reduced will be $\frac{15}{48}$.

9. *To reduce a vulgar fraction to a decimal of the ſame value,* ſee DECIMAL.

FRACTIONS, *Addition of vulgar.*—1. If the given fractions have different denominators, reduce them to the ſame. Then add the numerators together, and under the ſum write the common denominator. Thus, *e. gr.* $\frac{2}{3} + \frac{4}{5} = \frac{10}{15} + \frac{12}{15} = \frac{22}{15} = 1\frac{7}{15}$.

2. If compound fractions are given to be added, they muſt firſt be reduced to ſimple ones; and if the fractions be of different denominations, as $\frac{6}{8}$ of a pound, and $\frac{2}{3}$ of a ſhilling, they muſt firſt be reduced to fractions of the ſame denomination of pounds.

3. *To add mixt numbers.*—The integers are firſt to be added, then the fractional parts: and if the ſum be a proper fraction, only annex it to the ſum of the integers. If it be an improper fraction, reduce it to a mixed number, adding the integral parts thereof to the ſum of the integers, and the fractional part after it. Thus,

$$5\frac{2}{3} + 4\frac{1}{2} = \frac{17}{3} + \frac{9}{2} = \frac{34+27}{6} = \frac{61}{6} = 10\frac{1}{6}.$$

FRACTIONS, *Subtraction of.*—1. If they have the ſame common denominator, ſubtract the leſſer numerator from the greater, and ſet the remainder over the common denominator. Thus, from $\frac{9}{16}$ take $\frac{5}{16}$, and there remains $\frac{4}{16} = \frac{1}{4}$.

2. If they have not a common denominator, they muſt be reduced to fractions of the ſame value, having a common denominator, and then, as in the firſt rule. Thus, $\frac{5}{7} - \frac{2}{5} = \frac{25}{35} - \frac{14}{35} = \frac{11}{35}$.

3. *To ſubtract a whole number from a mixed number, or one mixed number from another.*—Reduce the whole, or mixed numbers, to improper fractions, and then proceed as in the firſt and ſecond rule.

FRACTIONS, *Multiplication of.*—1. If the fractions propoſed be both ſimple, multiply the numerators one by another for a new numerator, and the denominators for a new denominator. Thus $\frac{3}{4}$ into $\frac{5}{8}$ produces $\frac{15}{32}$.

2. If one of them be a mixed, or whole number, it muſt be reduced to an improper fraction; and then proceed as in the laſt rule. Thus, $\frac{2}{8}$ into $5\frac{2}{3}$, gives $\frac{34}{24}$, and $\frac{4}{9}$ into $\frac{10}{1} = \frac{40}{9}$.

In multiplication of fractions, obſerve that the product is leſs in value than either the multiplicand, or multiplicator; becauſe in all multiplications, as unity is to the multiplicator, ſo is the multiplicand to the product: or, as unity is to either factor, ſo is the other factor to the product. But unity is bigger than either factor, if the fractions be proper; and therefore either of them muſt be greater than the product.

Thus, in whole numbers, if 5 be multiplied by 8, it will be as 1 : 5 :: 8 : 40; or 1 : 8 :: 5 : 40. Wherefore in fractions, alſo, as 1 : $\frac{3}{4}$ :: $\frac{5}{8}$: $\frac{15}{32}$; or as 1 : $\frac{5}{8}$ :: $\frac{3}{4}$: $\frac{15}{32}$. But 1 is greater than either $\frac{3}{4}$ or $\frac{5}{8}$: wherefore either of them muſt be bigger than $\frac{15}{32}$.

FRACTIONS, *Diviſion of.*—1. If the fractions propoſed be both ſimple, multiply the denominator of the diviſor by the numerator of the dividend; the product is the numerator of the quotient: then multiply the numerator of the diviſor by the denominator of the dividend, the product is the denominator of the quotient. Thus $\frac{3}{7})\frac{4}{9}(\frac{28}{27}$. Or, invert the diviſor and proceed as in multiplication. 2. If either dividend, diviſor, or both, be whole, or mixed numbers, reduce them to improper fractions; and if they be compound fractions, reduce them to ſimple ones, and proceed as in the firſt rule.

In diviſion of fractions obſerve, that the quotient is always greater than the dividend; becauſe in all diviſion, as the diviſor is to unity, ſo is the dividend to the quotient: as if 3 divide 12, it will be as 3 : 1 :: 12 : 4. Now 3 is greater than 1; wherefore 12 muſt be greater than 4: but in fractions, as $\frac{7}{5}$: 1 :: $\frac{4}{9}$: $\frac{28}{27}$; where $\frac{7}{5}$ is leſs than 1; wherefore $\frac{4}{9}$ muſt be leſs than $\frac{28}{27}$.

FRACTIONS *in ſpecies*, or *algebraic quantities.*—1. *To reduce fractions in ſpecies to their leaſt terms.*—The numerators and denominators are to be divided by the greateſt common diviſor, as in numbers.

Thus the fraction $\frac{aac}{bc}$ is reduced to a more ſimple one $\frac{aa}{b}$ by dividing both aac and bc by c: and $\frac{203}{667}$ is reduced to a more ſimple one $\frac{7}{23}$ by dividing both 203 and 667 by 29; and $\frac{203\,aac}{667\,bc}$ is reduced to $\frac{7aa}{23b}$ by dividing by $29c$. And ſo $\frac{6a^3 - 9acc}{6aa + 3ac}$ becomes $\frac{2a^2 - 3cc}{2a + c}$ by dividing by $3a$. And $\frac{a^3 - aab + abb - b^3}{aa - ab}$ becomes $\frac{aa + bb}{a}$ by dividing by $a - b$. See COMMON *Meaſure.*

2. *To reduce fractions in ſpecies to a common denominator.*—The terms of each are to be multiplied by the denominator of the other.

Thus, having $\frac{a}{b}$ and $\frac{c}{d}$; multiply the terms of one $\frac{a}{b}$ by d, and alſo the terms of the other $\frac{c}{d}$ by b, and they will become $\frac{ad}{bd}$ and $\frac{bc}{bd}$, whereof the common denomi-

nator is $b\,d$. And thus a and $\frac{a\,b}{c}$ or $\frac{a}{1}$ and $\frac{a\,b}{c}$, become $\frac{a\,c}{c}$ and $\frac{a\,b}{c}$.

But where the denominators have a common diviſor, it is ſufficient to multiply them alternately by the quotients.

Thus the fractions $\frac{a^3}{b\,c}$ and $\frac{a^3}{b\,d}$ are reduced to theſe $\frac{a^3\,d}{b\,c\,d}$ and $\frac{a^3\,c}{b\,c\,d}$ by multiplying alternately by the quotients c and d, ariſing by the diviſion of the denominators by the common diviſor b. The other operations, with reſpect to numbers, are eaſily applied to algebraic quantities.

Addition and ſubtraction of fractions in ſpecies.—The proceſs is, in all reſpects, the ſame in ſpecies as in numbers. E. gr.

Suppoſe it be required to add the fractions $\frac{a}{b}$ and $\frac{c}{d}$.

Theſe, when reduced to the ſame denomination, will be $\frac{a\,d}{b\,d}$ and $\frac{b\,c}{b\,d}$; conſequently their ſum is $\frac{a\,d+b\,c}{b\,d}$.

So, if the fraction $\frac{a}{b}$ were to be ſubtracted from $\frac{c}{d}$; having reduced them they will be $\frac{a\,d}{b\,d}$ and $\frac{b\,c}{b\,d}$, as before. Their difference therefore is $\frac{b\,c-a\,d}{b\,d}$.

Multiplication and diviſion of fractions in ſpecies.—Here, too, the proceſs is perfectly the ſame as in vulgar arithmetic. Thus, *e. gr.* ſuppoſe the factors, or fractions, to be multiplied, $\frac{a}{b}$ and $\frac{c}{d}$: the product will be $\frac{a\,c}{b\,d}$.

Or ſuppoſe the fractions required to be divided, $\frac{a\,c}{b\,d}$ and $\frac{a}{b}$; the quotient will be $\frac{a\,c}{b\,d}\times\frac{b}{a}=\frac{a\,b\,c}{a\,b\,d}=\frac{c}{d}$.

Hence as $a=\frac{a}{1}$; the product of a into $\frac{c}{d}$, that is, of an integral quantity into a fraction, $\frac{c}{d}\times\frac{a}{1}=\frac{a\,c}{d}$. Whence it appears, that the numerator of the fraction is to be multiplied by the integer.

Hence, alſo, the quotient of $\frac{c}{d}$ by a, that is, of the broken quantity divided by the whole one, $\frac{c}{d}\times\frac{1}{a}=\frac{c}{a\,d}$.

Beſide the common notion of a fraction, there is another neceſſary to be underſtood. Thus,

Suppoſe $\frac{3}{4}$ of 20*s.* or a pound ſterling were the fraction: this fraction, inſtead of three quarters of one pound, may be conſidered as a fourth part of three pounds; that is, by taking as many of the integers as the numerator expreſſes (*viz.* 3), and dividing them by 4, the denominator, for then the quotient of the ſame value will ariſe; for 4) 60*s.* (15*s.* This ſhews the reaſon of that manner of expreſſion uſed by geometers and algebraiſts, who read $\frac{a}{b}$, thus, a divided by b.

Fraction, *continued*, is uſed for a fraction the denominator of which is a whole number with a fraction, the denominator of which is again a whole number and a fraction, and ſo on, whether this affection be continued *ad infinitum*, or whether the ſeries breaks off after a finite number of terms. Thus,

$$\frac{1}{2}+\frac{1}{3}+\frac{1}{4}+\frac{1}{5}+\text{, \&c.} \qquad \text{or } \frac{1}{2}+\frac{2}{3}+\frac{3}{4}+\frac{4}{5}+\text{, \&c.}$$

are continued fractions.

If we make uſe of letters inſtead of numbers, we ſhall have general expreſſions of theſe fractions, thus,

$$a+\frac{1}{b}+\frac{1}{c}+\frac{1}{d}+\frac{1}{e}+\frac{1}{f}+\text{, \&c.}$$

and

$$a+\frac{\alpha}{b}+\frac{\beta}{c}+\frac{\gamma}{d}+\frac{\delta}{e}+\frac{\varepsilon}{f}+\text{, \&c.}$$

The reduction of theſe continued fractions to thoſe of a common form is not difficult by the uſual rules of arithmetic and algebra. Thus to give an example which may at the ſame time ſhew the uſe of theſe continued fractions; ſuppoſe the continued fractions,

$$3+\frac{1}{7}+\frac{1}{15}+\frac{1}{1}+\frac{1}{292}+\frac{1}{1}+\frac{1}{1}+\text{, \&c.}$$

expreſs the circumference of a circle, when the diameter is one; if we ſtop at $\frac{1}{7}$, we ſhall have $3+\frac{1}{7}=\frac{21+1}{7}=\frac{22}{7}$. If we ſtop at $\frac{1}{15}$, we ſhall have

$$3+\frac{1}{7}+\frac{1}{15}=3+\frac{1}{\frac{106}{15}}=3+\frac{15}{106}=\frac{318+15}{106}=\frac{333}{106}$$

But if we ſtop at $\frac{1}{1}$, which is convenient on account of the ſmall fraction $\frac{1}{292}$ added to the laſt denominator 1, we ſhall then find, $3+\frac{1}{7}+\frac{1}{15}+\frac{1}{1}=\frac{355}{113}$. The firſt of the reductions give the proportion of Archimedes, and the laſt that of Adrian Metius.

But as beginning at the laſt denominator of the continued fraction makes the computation ſomewhat tedious, ſhorter methods have been contrived for the reduction of theſe fractions, and for a continued approximation to their true value. And Mr. Cotes's method for the reduction of ratios or ſmaller terms may be here applied. (See Ratio.) For it is to be obſerved, that when the numerators to the continued fraction are each units, the denominators will be the quotients ariſing from the continued diviſions in Mr. Cotes's method: or in the common, for reducing fractions to a lower denomination, which is in effect the ſame as Euclid's method for finding the greateſt common meaſure of two magnitudes, lib. x. prop. 3. But a detail of theſe things would lead us too far, we therefore refer the reader for

for a farther account of theſe continued fractions to Dr. Wallis's Arithmet. Infinit. prop. 191. Oper. vol. i. p. 469, ſeq. Huygens, Deſcript. Automat. Planetar. in Oper. poſthum. p. 173, ſeq. edit. Amſtelod. 1728, and particularly to Mr. Euler's Analyſ. Infinit. vol. i. cap. xviii. p. 295, ſeq. who has ſhewn the uſe and application of this doctine in many inſtances.

Lord Brouncker ſeems to have been the firſt who conſidered continued fractions, or at leaſt who firſt applied them to the quadrature of curves. The hint ſeems uſeful, but has been pretty much neglected, excepting in approximations to fractions or ratios expreſſed in great numbers. See the article RATIO. His ſeries for the quadrature of the circle, is

$$\square = 1\,\frac{1}{2}\,\frac{9}{2}\,\frac{25}{2}\,\frac{49}{2}\,\frac{81}{2},\ \&c.$$

in his and Dr. Wallis's notation, which amounts to the ſame thing as $1 + \frac{1}{2} + \frac{9}{2} + \frac{25}{2} +$, &c. in the notation of Huygens and Euler.

The ſymbol $\square$ denotes as before the ratio of the ſquare of the diameter to the area of the circle.

FRACTIONS, *Vaniſhing*, are thoſe in which the numerator and denominator vaniſh, or become equal to 0, at the ſame time. Thus, when any quantity N is expreſſed by a fraction $\frac{P}{Q}$, if P and Q vaniſh at the ſame time, we are not thence to conclude, that N is $= 0$. Suppoſe $N = \frac{a\,a - a\,x}{a - \sqrt{a\,x}}$; when $x = a$, the numerator and denominator of N vaniſh together; but if we reduce the value of N to a more ſimple form, by dividing the numerator and denominator by their common diviſor $\sqrt{a} - \sqrt{x}$, we ſhall find $N = a \times \frac{\sqrt{a} + \sqrt{x}}{a} =$ (when $x = a$) $a \times \frac{2\sqrt{a}}{\sqrt{a}} = 2\,a$. The idea of ſuch fractions originated, as Montucla has informed us (Hiſt. Math. vol. ii.) in a ſevere conteſt among ſome French mathematicians, in which Varignon and Rolle were the principal combatants, in reference to the differential calculus, then introduced, which Rolle ſtrenuouſly oppoſed. Among other arguments againſt it, he propoſed an example of drawing a tangent to certain curves at the point where the two parts croſs each other; and, as by that method, the fractional expreſſion for the ſubtangent, had both its numerator and denominator equal to 0, at the point propoſed, he conſidered the expreſſion as abſurd, and hence objected to the method of ſolution. The myſtery was ſoon explained, and firſt of all by Mr. John Bernouilli. Fractions of this kind have been often contemplated by later mathematicians; particularly by Maclaurin (Fluxions, vol. ii. art. 864.) Saunderſon (Algebra, vol. ii. art. 469.) Emerſon (Algebra, p. 212. apud Works, vol. iv.) and De Moivre (Miſcell. Anal. p. 165.) Theſe fractions were the occaſion of a ſharp controverſy between Powell and Waring in their competition for the profeſſorſhip at Cambridge. Waring maintained that the fraction $\frac{p - p^5}{1 - p}$ became 4, when p was $= 1$. Powell objected to this concluſion as abſurd, alleging that when $p = 1$, the fraction $\frac{p - p^5}{1 - p} = \frac{1 - 1}{1 - 1} = \frac{0}{0}$, and loſt the profeſſorſhip. Waring replied that $\frac{p - p^5}{1 - p}$ is $= p + p^3 + p^3 + p^1$ by common diviſion $= 1 + 1 + 1 + 1 = 4$, when p is $= 1$.

Mathematicians have propoſed two methods of finding the value of theſe fractions. The one is by conſidering the terms of the fraction as two variable quantities, continually decreaſing till they both vaniſh together; or finding the ultimate value of the ratio denoted by the fraction. Thus conſidered, it appears that, as the terms of the fraction are ſuppoſed to decreaſe till they vaniſh, or become only equal to their fluxions or increments, the value of the fraction, in that ſtate, will be equal to the fluxion or increment of the numerator divided by that of the denominator, *e.g.* take $\frac{x - x^5}{1 - x}$, when $x = 1$; the fluxion of the numerator is $\dot{x} - 5x^4\,\dot{x}$, and of the denominator $- \dot{x}$; conſequently $\frac{\dot{x} - 5\,x^4\,\dot{x}}{-\dot{x}} = \frac{1 - 5\,x^4}{-1} = \frac{5\,x^4 - 1}{1} = 5 - 1 = 4$; or the value of the fraction $\frac{x - x^5}{1 - x}$, when $x = 1$. Or thus, becauſe $x = 1$, $\frac{x - x^5}{1 - x}$ will be $= \frac{1 - x^4}{1 - x}$; then the fluxion of the numerator, $- 4\,x^3\,\dot{x}$, divided by the fluxion of the denominator, $- \dot{x}$, gives $4\,x^3$ or 4, as before.

The other method is by reducing the given expreſſion to another, in a more ſimple form, and then ſubſtituting the values of the letters. In the former example, $\frac{x - x^5}{1 - x}$ or $\frac{1 - x^4}{1 - x}$, when $x = 1$, divide the numerator by the denominator, and it becomes $1 + x + x^2 + x^3$, which, x being $= 1$, becomes 4 for the value of the fraction, as before. Again, to find the value of $\frac{a\sqrt{a\,x} - x\,x}{a - \sqrt{a\,x}}$, when x is $= a$, in which caſe both the numerator and denominator become $= 0$; divide the numerator by the denominator, and the quotient $\sqrt{a\,x} + x + x\sqrt{\frac{x}{a}}$, when, x being $= a$, becomes $a + a + a = 3\,a$, for the value of the fraction in that ſtate of it. Hutton's Math. Dict. For a farther view of this ſubject, and particularly of Mr. Woodhouſe's objections againſt vaniſhing fractions; ſee *Analytical* FUNCTION.

FRACTION, *Repetend of a decimal.* See REPETEND.

FRACTION, *Logarithm of a.* See LOGARITHM.

FRACTIONS, *ſumming of infinite.* See CALCULUS, and FLUXIONS.

FRACTION, in *Muſic*, is one of the terms implying a part or remainder, which Mr. Overend and other writers on the theory or magnitudes of muſical intervals have adopted as the general name of three different intervals; indeed nearly all the names of ſmall muſical intervals have almoſt the ſame meaning in ſome language, becauſe they all had their origin, or owed their diſcovery from taking the concords, the only intervals marked ſtrongly by nature, from each other, and theſe differences or reſidual intervals again from each other reſpectively, and thus ultimately, what may be called the elementary intervals have been obtained, as the ſame are exhibited in a table, plate V. in vol. xxviii. of the Philoſophical Magazine. See INTERVAL.

Leſſer

Leſſer Fraction of Mr. Overend is an interval, which reſults either by taking a minor comma from a priſma, or a ſemi-comma maxime from a greater reſidual; it is the ſmalleſt interval but one which is yet known, is marked *f*, and forms the ſecond or intermediate term in Mr. Farey's new notation, wherein it has the curious and important property of pointing out, beginning with the ſemitones, and aſcending to what finger-key of the common or Douzeur ſcale any interval belongs; thus $358\,\Sigma + 7\,f + 31\,m$, the expreſſion for the fifth in this notation, ſhews, that it contains ſeven half-notes or finger-key intervals, and ſo of any other interval.

Its ratio is $\frac{450,283,905,890,997,363}{450,395,952,737,049,600}$, which in its component primes is $\frac{3^{17}}{2^{14}\,5^{2}}$; in the new notation it is marked *f*; its common logarithm is .9999266,5010, whereof the reciprocal is 733,4990; its binary or Euler's logarithm is .000259: it having that decimal relation to the octave 1. It is equal to .01,3601 major commas, of which it is the $\frac{1}{73.55198}$ part; it is equal 19.03541 minutes, of which it is the $\frac{1}{.05254}$ part; alſo to .149661 ſchiſmas, of which it is the $\frac{1}{6.5297}$ part.

This interval reſults from the ſubtraction of numerous intervals, as two ſchiſmas from a minor reſidual, three ſchiſmas from a medius reſidual, four ſchiſmas from a ſemi-comma major, five ſchiſmas from a ſemi-comma maxime, two medius reſiduals from three minor reſiduals, five radius reſiduals from three greater reſiduals, two greater reſiduals from five minor reſiduals, a ſemi-comma major from two minor reſiduals, three ſemi-commas major from four medius reſiduals, three diaſchiſmas from a minor ſemitone; this interval alſo reſults when 14 fifths and two minor thirds are taken from 21 minor fourths, but theſe tuneable intervals do not furniſh a practicable mode of tuning this, perhaps, unappreciable interval, becauſe pipes to the compaſs of near nine octaves would be wanted for putting the ſame in practice.

Medius fraction of Dr. Callcott, is an interval which reſults as the difference between a major and a greater reſidual; it is marked *d* in Dr. C's MSS. its ratio is $\frac{50,000,000,000,000,000}{50,031,545,098,999,707}$, which in primes is $\frac{2^{16}\,5^{17}}{3^{35}}$; its value in the new notation is $\Sigma - 3\,f + m$, its common logarithm is .9997260,8915, and reciprocal 2739,1085; its binary or Euler's log. is .000893, and it is .05077 major commas; it is .55888 times the ſchiſma; it reſults as the difference between a greater fraction and two leſſer fractions, and between a minor comma and three medius reſiduals, alſo between the ſum of a ſchiſma and minute and three leſſer fractions, alſo between the ſum of three ſchiſmas and an apotome, and four hyperoches: if 17 minor thirds be added to three fifths and fifteen minor fourths deducted, therefore this interval reſults, but it can ſcarcely admit of accurate tuning by this method, on account of the great number of intervals to be tuned.

Greater fraction of Mr. Overend, is an interval that does not reſult from the ſimple ſubtraction of any two of M. Overend's intervals, but is the ſum of a medius fraction and two leſſer fractions, it is marked F, its ratio is $\frac{4,946,832,462,181,367,513,427,734,375}{4,95\,,760,157,141,521,099,596,496,496} = \frac{3^{39}\,5^{13}}{2^{31}} = \Sigma - f + m$; its common logarithm is .9995793,8935, and reciprocal 4206,1065, its binary log. = .001411; it is = .07797 major commas, and .858202 ſchiſmas; it is the difference between a major reſidual and five ſchiſmas, and between an octave and 13 medius ſemitones; it is the difference between a ſigma and minute, and a leſſer fraction, between a major comma, a minute, and a priſma, between a major reſidual and priſma and a hyperoche. When 25 major thirds and 12 minor thirds are taken from 27 fourths, or when 12 fifths and 13 major thirds are taken from 27 fourths, this interval reſults, but it can ſcarcely admit of correct tuning by theſe methods.

FRACTURE, in *Surgery*, may be defined to be a ſolution of continuity in a bone, commonly occaſioned by external violence; but ſometimes by the powerful action of the muſcles, as is almoſt always the caſe with regard to the knee-pan. The diviſion of a part of a bone with a cutting inſtrument, ſuch as a ſabre, is not uſually conſidered as belonging to the claſs of injuries called fractures, although it will certainly fall within the meaning of the words employed in our definition. However, as every perſon of common ſenſe knows that there is a difference between breaking things and cutting them, we ſhall not offer any apology for the circumſtance of our definition being more comprehenſive than it ſtrictly ought to be. The imperfection is obvious; but, we believe, not very eaſy of removal: all the moſt diſtinguiſhed ſurgical authors have been obliged to be content with defining a fracture in terms, more or leſs, like thoſe which we have ventured to uſe.

General Remarks on Fractures.

Fractures are divided into *ſimple*, *compound*, and *comminuted*.

A *ſimple fracture* is one, in which the bone or bones are only broken in one place, while the ſoft parts remain free from any external wound, communicating internally with the fracture.

A *compound fracture* is ſo called, when the injury of the bone or bones is conjoined with a wound of the integuments; which wound leads down to the fracture, and is in general occaſioned by a protruſion of the broken part of the bone or bones through the ſkin.

A *comminuted fracture* is ſo named, when the injured bone is broken into ſeveral pieces.

The fractured bone may be broad, like the ſcapula and bones of the pelvis; or, it may be ſhort and thick, like the bones of the tarſus and carpus; or, laſtly, it may belong to that long ſet of bones, which are uſually termed by anatomiſts cylindrical.

All the bones of the body are not equally expoſed to fractures. Some are more or leſs protected from the effects of external violence by their ſituation; others, by their ſhape and ſtrength. On the other hand, ſome are particularly often broken, in conſequence of their being ſo placed in the body as to be very liable to receive the force of blows, falls, &c.; while other bones are frequently fractured, on account of their having a certain figure and ſtructure, which render them weak, and incapable of making any conſiderable reſiſtance.

The broad, flat bones are, for the moſt part, ſo ſituated, and ſo circumſtanced, with reſpect to their uſes, that they are not often fractured. The bones of the cranium, and ſome parts of the ſcapula, however, are an exception to this obſervation.

The ſhort, thick bones are ſtill leſs frequently broken. Indeed, their ſhape gives them ſuch ſtrength, and they are generally ſo ſurrounded with elaſtic cartilaginous matter, that

that they can hardly be fractured, without the operation of ſome conſiderable violence particularly directed againſt them. Hence, when they are broken, it is almoſt always in conſequence of their being cruſhed by ſome heavy weight, or waggon-wheel; or by their being ſtruck by a cannon ball, or bullet. We have one exception to make to this remark: the patella, which ranks as a ſhort thick bone, is very often broken; and this by a cauſe widely different from that which uſually produces the fractures of other bones of a ſimilar form. The patella is occaſionally ſplit into two pieces by the powerful action of the muſcles concerned in the extenſion of the leg. Many perſons rate the ſtrength of the muſcles exceedingly high; but few, unacquainted with the facts which preſent themſelves in ſurgery, would have any conception that the muſcles could rend the firm texture of the bones with which they are connected.

The long cylindrical bones, as Boyer remarks, whether they ſerve as pillars, as levers, or as arch-ending points of reſiſtance and ſupport, are more frequently fractured than any other deſcription of bones. They may be broken at any part; but the breach of continuity, in the majority of inſtances, happens at the point of biſection: the fracture being produced, like that of a ſtick bent beyond its natural extenſibility, by a force applied at each extremity. However, the cylindrical bones are alſo ſubject to be fractured near their ends, ſometimes even at their extreme points, as will be ſeen when we treat of fractures of the neck, of the thigh-bone, and humerus.

This diverſity in the ſituation of fractures of the long bones makes a material difference with reſpect to the trouble which is likely to attend the treatment. A fracture near the middle of the bone is the leaſt dangerous; for although the bone is there more ſlender, and the ends of the fracture more apt to be ſeparated, on account of the ſurfaces oppoſed to each other being leſs extenſive, yet the cauſe of the accident, in this kind of caſe, has ſeldom been applied directly to the broken part, and, of courſe, the adjacent ſoft parts are generally free from injury. Beſides, it is a well-known fact, that much more violence is required to break the bone near one of its ends than in the middle; and, conſequently, the firſt caſe muſt commonly be attended with more ſerious miſchief. It is alſo obſerved by Boyer, that the treatment of ſuch fractures, as happen about the middle parts of the long cylindrical bones, can be more effectually conducted, becauſe the apparatus, uſually employed to keep the ends of the fracture in contact, extends a conſiderable way both below and above the ſituation of the injury. In addition to theſe reaſons, why fractures near the heads of the long bones are moſt troubleſome to manage, and moſt dangerous in their conſequences, we have to mention that, in theſe examples, the neighbouring joint is alſo apt to inflame, become ſtiff, and ſometimes affected with an incurable anchyloſis.

Another circumſtance, making a material difference in fractures, is the particular direction which they take, with regard to the axis of the bone, in various caſes. In ſome inſtances, the breach of continuity runs tranſverſely; in others, obliquely. Certain authors, as Duverney and Heiſter, have enumerated and admitted, beſides *tranſverſe* and *oblique* fractures, alſo *longitudinal* ones. But M. Louis and Boyer, with every appearance of reaſon, reject as impoſſible the longitudinal fracture; unleſs by that expreſſion are ſignified the longitudinal ſplinters of comminuted fractures; which ſplinters are very apt to attend theſe injuries, when they are occaſioned by gun-ſhot violence.

A knowledge of the kinds of diſplacement (if we may uſe this term) to which the ends of a fracture are liable, and of the manner in which ſuch diſplacement is produced, is highly important in practice: for the grand object in the treatment conſiſts in preventing the extremities of the fracture from becoming ſeparated, and in rectifying their poſition, whenever they happen to be diſplaced

From the vague, inaccurate way in which the general ſymptoms of fractures are repreſented by moſt ſurgical writers, we ſhould ſuppoſe that the ends of all fractures are neceſſarily diſplaced, and that theſe accidents are invariably attended with deformity. Nothing, however, can be further from the truth than this idea. It is true, that the great ſkill, in the treatment of fractures, conſiſts in keeping the ends of the broken part of the bone in a ſtate of contact; but we are not to infer from this circumſtance, that becauſe a bone is broken, and *may* be diſplaced, that it *muſt always* be ſo. Were we to pronounce that there is no fracture, becauſe there appears no deformity, our deciſion, ariſing from this criterion, would often diſplay ignorance, and be productive of highly miſchievous conſequences to the patient. The leg, that part of the body ſo peculiarly expoſed to a variety of accidents, is frequently broken, while the form of the limb remains unchanged. The caſe which often preſents us with a ſtriking illuſtration of this fact, is when the tibia only is fractured near its upper head, where its diameter is conſiderable, and conſequently the ſurfaces oppoſed to each other ſo extenſive, that they are hardly capable of being ſeparated. In this inſtance, the fibula alſo operates as a ſplint, and keeps the extremities of the fracture in their proper ſituation.

Deſirous, as we have been, of correcting the miſtaken notion, that deformity is a ſymptom *always* attendant on fractures, we ſhould be ſorry to convey to any one a falſe idea, that a deviation of the broken part of a bone from its right and natural poſition, and a conſequent alteration in the original ſhape and appearance of the limb, or part, are not very frequently among the moſt certain ſigns by which the nature of the accident may be known. Fractures of the arm and thigh are, almoſt without exception, attended with deformity, in conſequence of the ends of the broken part of the bone not continuing properly applied to each other. It is the ſame with fractures of the clavicle, as well as with all thoſe in which both bones of the leg and both bones of the fore-arm are concerned.

The derangement to which fractures are ſubject may happen in the direction of the diameter of the bone; be parallel to, or form an angle with, the axis; or merely affect the circumference.

Boyer obſerves, that when a bone is fractured tranſverſely, the contiguous ſurfaces may remain in partial contact, or be totally ſeparated. In a fracture of the tibia, for inſtance, the inferior portion of the bone may be puſhed inward, and totally ſeparated from the ſuperior; or the external part of the former may be placed in contact with the internal of the latter. This incomplete derangement in the direction of the diameter of the bone does not produce any ſhortening of the limb; but when the tranſverſe derangement is complete, then follows that parallel to the axis of the bone. The derangement in the direction of the diameter happens when the fractured bone is of a conſiderable ſize, as the tibia, for inſtance, when the fracture is tranſverſe, and when the proper means of keeping the parts in their natural ſituation have been neglected. But, if the fracture be oblique, the ſurfaces not extenſive, and the accident neglected, the derangement in the direction of the axis takes place, and the limb is ſhortened. Boyer, alſo, notices that the derangement which attends ſuch fractures

as thoſe of the patella, olecranon, &c. might be claſſed with the preceding kind; but with this difference, that the fractured ends, inſtead of riding over each other, recede one from the other, and are always found ſeparated by a greater or leſs diſtance.

Boyer remarks, that the third ſpecies of derangement, or that in which the two portions of a broken bone form an angle one with the other, takes place principally in caſes of comminuted fractures. However, a ſimple fracture of the leg might be diſplaced in this manner, as may eaſily be conceived, by ſuppoſing the foot placed on an inclined plane, in which caſe, the angle formed would be ſalient anteriorly, if the heel were lower than the fore part of the foot; poſteriorly, if the contrary.

The fourth ſpecies of derangement noticed by Boyer, or that affecting the circumference, is produced by the rotation of the inferior portion of the fractured bone on the ſuperior, in ſuch a manner, that the part which was anterior becomes internal, or external. We have an inſtance of this ſpecies of derangement in the fracture of the neck of the thigh bone, when the foot, being ill ſupported by the apparatus, and obeying its weight, aided by that of the leg, and by the contraction of the muſcles, turns outward, and carries the lower portion of the broken bone in the ſame direction. In this caſe the anterior part of the body of the bone correſponds no longer to that of the neck.

It is explained by the above-mentioned writer, that as the bones are only paſſive inſtruments of locomotion, they poſſeſs not, in their own organization, any cauſe of the change of ſituation which takes place with reſpect to the ends of fractures. The cauſes are all aſcribable to external impulſes, the weight of the limb, and the contraction of muſcles. The cauſe of the fracture may be the cauſe of the derangement of the fractured portions. Thus, when the thigh is broken by a fall from ſome height, the weight of the body on the leg, which reſts on the ground, may, beſides bending the thigh bone forward, and breaking it, alſo diſplace the ends of the fracture.

The celebrated ſurgeon Ambroſe Paré had his leg broken, and the ends of the fracture diſplaced by the ſame cauſe. The lower portion of the broken bone was quite ſeparated from the upper, while the latter, driven by the weight of the body, was forced through the integuments, ſtocking, &c. into the very ground.

The angular and the rotatory derangement of the fractures may be occaſioned by the aukward manner in which the aſſiſtants hold the broken limb, as well as by the weight of the limb itſelf. The action of the muſcles, however. is the moſt powerful circumſtance by which the generality of fractures are diſplaced.

It was that great ſurgeon, Mr. Pott, who firſt fixed the earneſt attention of the ſurgical profeſſion on the conſiderable ſhare which the muſcles had in drawing the ends of fractures out of their proper poſition, and in diſplacing them again after they had been ſet.

The ears of every reader muſt be familiarly acquainted with the phraſe of *ſetting* a broken bone; and there is ſcarcely a perſon who does not immediately think, that when a limb is fractured, ſome force muſt be directly uſed, in order to bring the extremities of the fracture into a ſtate of even contact with reſpect to each other. Many, who call themſelves ſurgeons, never take the trouble to conſider whether the ends of a fracture are diſplaced or not. No ſooner do they feel a crepitus, and aſcertain that a bone is broken, than they take it for granted that the extremities of the fracture muſt of courſe be out of their proper place, and that no time ſhould be loſt before they are forcibly pulled back again.

The old writers on ſurgery direct us, in caſes in which the thigh or leg is broken, to place the patient in a ſupine poſture, and the broken limb in a ſtraight one; then, having the upper part of it held firm and ſteady, by proper aſſiſtants, we are ordered, by means of bands, ligatures, or even, in ſome caſes, by pieces of machinery, to make ſuch an extenſion or ſtretching of the limb lengthways, as ſhall enable the ſurgeon to place the ends of the broken bone in as even a poſition, with regard to each other, as the nature of the fracture will admit. "This," ſays Mr. Pott, "is a ſhort deſcription of what, in the vulgar phraſe, is called ſetting a broken bone; and is moſt commonly a painful operation to the patient, a fatiguing one to the operator and his aſſiſtants; and, what is worſe, is, in many inſtances, found to be inefficacious; at leaſt, not fully to anſwer the intention of the one, or the expectation of the other."

After dwelling on the difficulty, inefficacy, and miſchief attending ſuch practice, Mr. Pott remarks, that neither extenſion, nor counter-extenſion, can ever be neceſſary, on account of the mere fracture, conſidered abſtractedly. The broken ends of the bone, or bones, are of themſelves inactive, and, if not acted upon by other parts, they would always remain motionleſs. When any attempt is made to put them in motion, they of themſelves can make no poſſible reſiſtance; nor can any be made on their part, ſave an accidental one ariſing from the points of the fracture being entangled with each other; and when they have been once, by the hand of the ſurgeon, placed properly and evenly with regard to each other, they would of themſelves for ever remain ſo. What, then, is the reaſon why fractured bones always ſuffer a greater or leſs degree of diſplacement? Why is a broken limb almoſt always ſhorter than its fellow? What creates the reſiſtance which we always find in attempting to bring the fractured parts aptly together? Whence does it proceed, that when we have done all that is in our power, (according to this mode of acting,) the ends of the fracture will, in many caſes, become again diſplaced, and lameneſs and deformity frequently enſue? In ſhort, what are the parts, or powers, which act on the bones, and which, by ſo acting on them, produce all theſe conſequences?

Theſe parts, ſays Mr. Pott, are the muſcles, the only moving powers in the animal body. By the action of theſe on the bones all locomotion is performed, and cannot be performed without them; and, although all bones, when broken, are generally in ſome degree diſplaced and ſhortened, yet it will always be found, that in proportion as the muſcles ſurrounding, or in connection with a bone, are ſtrong, or numerous, or put into action by inadvertence or ſpaſm, ſo will the diſplacement of the ends of ſuch bone, when fractured, be. The even and ſmooth poſition of the fractured ends of a tibia, when the fibula of the ſame leg is entire and unhurt, that is, when the muſcles therefore cannot act upon the former; the viſible and immediate deformity, when both the beforementioned bones are broken nearly in the ſame place, that is, when the muſcles can act upon and diſplace ſuch fracture; the great difficulty frequently met with in endeavouring to get a broken os femoris to be even tolerably ſmooth, and to prevent ſuch broken limb from being much ſhorter than the other, are, among others which might be produced, ſuch ſtrong and irrefragable proofs as need no comment.

A very remarkable caſe is cited in "Les Oeuvres Chirurgicales de Deſault par Bichat," to ſhew that the derangement of

of broken thighs is occaſioned by the action of the muſcles. The patient was a carpenter, who had fallen from a ſcaffold, and broken his thigh. On the day after the accident the limb was as long as the other; but the lower extremities were both affected with a complete paralyſis, attended with a retention of urine. However, no ſooner had the muſcles recovered their power of action, in conſequence of moxa being applied, than the ſhortening of the limb made its appearance.

When we come to the conſideration of particular fractures we ſhall have occaſion to point out what muſcles have the moſt conſiderable effect in ſeparating the ends of the broken bone from each other, and what plans may be adopted for the prevention of ſuch diſplacement.

Writers have diſtinguiſhed the cauſes of fractures into two kinds, namely, prediſpoſing and remote.

Among the prediſpoſing are uſually enumerated the ſituation and function of the bones, the age of the patient, and certain diſeaſes under which he may be labouring.

Thus, as Boyer has obſerved, ſuperficial bones are more eaſily fractured than ſuch as are covered with a conſiderable quantity of fleſh. Thus, the radius which ſupports the hand, and ſerves as a kind of handle for it, is more apt to be broken than the ulna. The clavicle alſo is very frequently fractured, in conſequence of its office, which is to keep the ſhoulder in its proper poſition, and bear upon its arched extremity all the motions of the arm.

The bones of old ſubjects are exceedingly brittle, on account of the great quantity of phoſphate of lime contained in their texture, in proportion to the animal matter; or, in other words, by reaſon of the large proportion of the inorganized to the organized part of their ſtructure. On the contrary, the bones of children and young perſons contain a large quantity of fibrous, elaſtic, animal matter, and a ſmaller proportion of earth, ſo that they are very flexible and yielding, by which means they often elude the effects of external violence, and remain unbroken.

Louis and Saviard have related examples, in which female patients labouring under old ulcerated cancers, have had their bones affected with ſuch brittleneſs, that merely moving in bed would break ſome of them. Here the firſt indication is to correct, if poſſible, the ſtate of the ſyſtem which is the cauſe of the fragility of the bones.

Some authors have been abſurd enough to impute the frequency of fractures in cold weather to the bones being then more brittle, as if the great number of falls which happen on icy ſlippery places in the winter ſeaſon were not a more rational explanation of the fact. With regard to the ſymptoms of fractures, ſeveral are only of an equivocal nature, as, for inſtance, the pain, and the difficulty or impoſſibility of moving the limb. The ſame obſervation is alſo applicable to the ſhortening of the limb, and the alteration in its ſhape, which are ſometimes the conſequence of fractures. However, no certain inference can be drawn from theſe ſigns, unleſs it be firſt aſcertained that the deformity is not natural, and does not proceed from a diſlocation. It is true, the limb may occaſionally form ſuch an angle at the broken part, and the ends of the bones may be ſo prominent, that the accident cannot fail to be apparent to the moſt careleſs and leaſt diſcerning examiner. However, this clearneſs in regard to the nature of the caſe is only occaſional, and many fractures are attended with a kind of deformity which involves things in more doubt.

The reader is not to imbibe the ſuppoſition that all fractures are attended with deformity; nor muſt he think, on the other hand, that becauſe there is no change in the ſhape and external appearance of the limb, or part, there is certainly no fracture.

The moſt certain ſymptom of a fracture is what is termed a crepitus, by which is meant, that grating ſenſation and noiſe which the fingers and ears of the ſurgeon have communicated to them when the ends of the fracture rub againſt each other.

Surgeons are generally too ſolicitous about feeling the crepitus, whenever they ſuſpect a fracture. It is undoubtedly the leaſt ambiguous of the ſigns by which the accident may be known; but let it be remembered, that rubbing the ends of a broken bone againſt each other, and againſt the ſurrounding fleſh, puts the patient to moſt excruciating torture, and aggravates all the inflammatory ſymptoms which muſt enſue. Hence, whenever the nature of the caſe is ſufficiently evident from the bent appearance of the limb, projection of the ends of the bone, &c. it does not become a humane practitioner to move and diſturb the fracture for the purpoſe of feeling the crepitus. Such conduct would only be gratifying a moſt uſeleſs kind of curioſity at the expence of much ſuffering to the poor patient.

In ſome inſtances of fractures no crepitus can be diſcovered; nor is there any other ſymptom preſent by which the exiſtence of the accidents can be detected with abſolute certainty. Several cauſes may be the occaſion of this obſcurity. In particular caſes, the injured bone is ſurrounded by ſo conſiderable a quantity of fleſh, that it is next to impoſſible to feel the breach of continuity, or perceive a crepitus. In an example of this kind, the accident may continue for ever undiſcovered, if the ends of the fracture are not materially ſeparated, and, conſequently, there is no deformity. Fractures of the neck of the thigh-bone are often circumſtanced in the foregoing manner. A fracture of the tibia, fibula, or ulna, alone, is frequently very difficult to diſcover, becauſe the other bone, which remains uninjured, prevents any change in the ſhape of the limb, and keeps the ends of the fracture from moving with ſufficient freedom to communicate the diſtinct ſenſation of a crepitus.

We ſhall conclude theſe obſervations, relative to the diagnoſis of fractures, with earneſtly exhorting ſurgeons, in all caſes of doubt, to act in the ſame way as they would do were they certain of there being a fracture. The application of a bandage, ſplints, &c. can never do harm, and may be the means of preſerving the patient from irremediable deformity and lameneſs. Every experienced practitioner knows how difficult it frequently is to feel a diſtinct crepitus when a ſingle rib is broken; but, becauſe he cannot actually perceive the ends of the bone grate, he does not omit to apply a tight bandage round the thorax, provided the kind of pain which the patient complains of in reſpiration, and the nature of the blow, juſtify a ſuſpicion that the accident has happened.

On the ſubject of the prognoſis we have to remark, that, in general, fractures of bones, which are acted upon by numerous powerful muſcles, are more troubleſome to cure than other fractures which befall bones differently circumſtanced.

Fractures of the arm are generally attended with leſs danger than thoſe of the leg.

Fractures which take place near the middle of a long bone are uſually not ſo ſerious in their conſequences as fractures which happen in the vicinity of a joint. In the firſt caſes, the force has commonly operated at ſome diſtance from the breach in the bone, and the ſoft parts immediately round the fracture have conſequently not ſuffered any conſiderable degree of contuſion. But, when the head of a long bone is broken, the force has in general been ap-

plied directly to the fractured part, ſo that the ſkin and muſcles are more injured than in the preceding kind of caſe; and, as the neighbouring joint is liable to inflame, anchyloſis is apt to enſue. Another reaſon why a fracture of the head of a long bone is troubleſome to cure, is, that the ſplints cannot effectually keep the ſhort fragment ſteady.

Oblique fractures of the limbs are far more dangerous than tranſverſe ones, becauſe the two ſloping ſurfaces ſlip over each other, and make no reſiſtance to the muſcles, which have a continual tendency to draw upward the lower part of the broken bone.

Compound fractures are infinitely more hazardous than ſimple ones, and often terminate in the loſs of the limb, or even of the patient's life. The practitioner is frequently called upon to exerciſe the niceſt judgment and diſcrimination in determining whether an attempt ſhould be made to ſave the limb in theſe caſes, or amputation be at once performed.

The peril attendant on all fractures may be greatly increaſed by the ſoft parts being conſiderably contuſed or lacerated, by ſome large artery being wounded, &c.

Fractures of the lower extremities, *cæteris paribus*, are accounted more dangerous and difficult of cure than thoſe of the arm and fore-arm.

It ſeems hardly neceſſary to obſerve, that the patient's age, and the ſtate of his health, make a material difference in the degree of danger attendant on a fracture. A debilitated old man cannot be expected to get well ſo often and expeditiouſly as a younger perſon, poſſeſſing a fine conſtitution. Childen's fractures are united with aſtoniſhing quickneſs.

The ſcurvy is ſaid to hinder broken bones from uniting, by preventing the formation of callus. Authors have alſo aſſerted, that pregnancy has the ſame effect; but Boyer does not believe this to be true, and our own experience enables us to corroborate what this laſt author has ſtated; for we attended, a few years ago, a young woman who broke both bones of her leg, when five or ſix months advanced in pregnancy, but who, notwithſtanding her ſtate, recovered in leſs than two months.

There are certain perſons, in whom bones which happen to be fractured, remain diſunited throughout life; nor can any very good explanation of the reaſon of this circumſtance be afforded. In the ſituation of the fracture a ſupernumerary joint is formed, and the limb continues for ever afterwards flexible in a ſituation where it ought not to be ſo. On this ſubject we ſhall have occaſion to ſay a few words again.

The general doctrine relative to the treatment of fractures has been arranged under the following heads:

Extenſion.
Counter-extenſion.
Coaptation, or Setting.
Application of Medicaments.
Deligation, or Bandage.
Poſition.
Prevention, or Relief of Accidents.

In every caſe of fracture, where the ends of the broken part of the bone are diſplaced, it is obviouſly the firſt indication to put them into an even and natural poſition with regard to each other. It is only with this view that extenſion and counter-extenſion are ever requiſite.

Extenſion is the force exerted on the lower portion of the broken bone, in order to bring down its upper end into a ſtate of coaptation with the lower end of the upper piece of the ſame bone. Counter-extenſion is a reſiſting force, employed to prevent the whole limb, or even the whole body, from obeying the force of extenſion.

The reader is already apprized of the various kinds of derangement to which fractures are ſubject, and alſo of the principal ſhare which the muſcles have in diſplacing the ends of broken bones, reſiſting their coaptation, and putting them out of their proper poſition again, after they have been ſet. Such information muſt at once lead us to perceive that both in the ſetting, and throughout the whole of the treatment of fractures in general, the great ſurgical aim is to diminiſh as much as poſſible the power of ſuch muſcles as have moſt influence in throwing the ends of the broken bone out of their right poſition.

Mr. Pott undertook to conſider what it was which gave to a muſcle, or to the principal muſcles of a limb, the greateſt power of reſiſting any force applied to them *ab externo*, in order to draw them out into greater length; for, ſays he, whatever that is, the ſame thing will be found to be the cauſe of the different degrees of reſiſtance in ſetting a fracture.

This eminent ſurgeon contends, that putting the muſcles into a ſtate of tenſion, or into a ſtate approaching nearly to that of tenſion, almoſt neceſſarily gives them an opportunity of exerting their greateſt power, either of action or reſiſtance. On the other hand, he enquires what is the ſtate or poſition of a muſcle, which is moſt likely to prevent it from acting, and diminiſh, as much as poſſible, its power of reſiſtance? Or, what is that poſition of a limb which, in the caſe of a broken bone, will moſt incapacitate the muſcles from acting on and diſplacing it; and which will, in the greateſt degree, remove that reſiſtance which they have it in their power to make to the attempts for the reduction of ſuch fracture? Mr. Pott believed, that putting a limb into a poſition which relaxes the whole ſet of muſcles belonging to the broken bone, muſt beſt anſwer ſuch purpoſe, and, conſequently, he urgently recommended ſurgeons to put the limb into this poſture at the time of making the extenſion and reducing the fracture. In caſes of broken thighs and legs, the poſition which he adviſed was that in which the limb lies on its outſide, with the knee half bent, and the thigh in a ſimilar ſtate, as will be hereafter deſcribed.

Practitioners have undoubtedly received from the able writings of Pott a great deal of valuable information; and enforced, as all his precepts are, in an authoritative, animated ſtyle, they make conſiderable impreſſion, and are, perhaps, too liable to be received as incontrovertible truths, needing no further inveſtigation. When we are told that relaxing a muſcle, or bringing its origin and inſertion nearer together, diminiſhes its power, we ſee the truth of the obſervation, becauſe a muſcle acts by ſhortening itſelf; and it obviouſly can only ſhorten itſelf to a certain degree. But when we are adviſed to put a limb into ſuch a poſition as ſhall relax the whole ſet of muſcles, which have the power of moving the broken bone, we are puzzled to conceive what poſture can be meant; for it is evident, that when we bend a joint, we make the extenſor muſcles tenſe; and, that when we ſtraighten it, we put the flexors on the ſtretch. In the preciſe poſitions which Mr. Pott recommends for fractured thighs and legs, ſo far is the whole ſet of muſcles from being relaxed, that many of them may be ſaid to be very much on the ſtretch; and, in the caſe of a broken arm, with the elbow bent, are not the triceps and anconæus in a ſtate of tenſion, in conſequence of the ſame poſture, by which the biceps and brachialis internus are relaxed?

By theſe obſervations we are far from intending to inſinuate, that any of the poſtures, to which alluſion has been made, are not ſuch as ought to be preferred. Our preſent

deſign

deſign is only to ſhew, that to entertain an idea that every muſcle, belonging to a bone, may be relaxed by bending a joint, is abſurd in the extreme.

It is by no means true that, in every fracture, extenſion and counter-extenſion are requiſite: in fractures of the patella and olecranon they would abſolutely be improper. In theſe examples, it is only neceſſary to extend the leg and fore-arm, ſo as to relax the muſcles which draw up the upper piece of the bone, and then it may eaſily be puſhed into contact with the lower portion.

When the derangement is in the direction of the diameter of the bone, a very little extenſion is enough; as here the only object of it is to diminiſh the friction of the ſurfaces of the fracture, which are to be moved in oppoſite ways.

When the two portions of a broken bone form an angle with each other, no extenſion and counter-extenſion are neceſſary; and the ſurgeon has only to put the limb on a horizontal plane, in order to bring the bone into its right poſition.

It is equally evident, that the rotatory derangement of a fracture requires no ſuch proceedings, ſince the bone may be ſet right by merely turning the lower fragment in a direction contrary to that in which the fracture has been diſplaced.

Extenſion and counter-extenſion, then, can only be of real uſe when the derangement happens in the direction of the axis of a bone.

It is not an uncommon ſuppoſition, that a fractured limb may be in ſuch a ſtate as not to admit of the extenſion neceſſary for its being ſet; and when much ſwelling, inflammation, and pain, affect the member, ſome practitioners confine their attention at firſt entirely to theſe ſymptoms. Under this method of treatment, the ſpace of time which is loſt in relieving theſe complaints is ſometimes conſiderable; ſo conſiderable that, as Mr. Pott obſerves, an even coaptation becomes afterwards impracticable: and then the inflammatory ſymptoms, which nine times in ten are capable of immediate relief, are urged as an excuſe for unneceſſary lameneſs and deformity.

The fact is, no fracture which is diſplaced ſhould ever be allowed to remain ſo: the moſt powerful of thoſe muſcles which produce the derangement ought, if poſſible, to be relaxed, by placing the limb in a judicious poſture; and in ſuch poſture the bones ſhould be ſet, without one moment's time being loſt. The coaptation of the fracture is, in fact, the moſt effectual means of diminiſhing the tenſion, ſwelling, and pain in the limb; as any one may conceive, who has a juſt notion of what miſchief the rough, ſharp extremities of an unſet fracture muſt do to the ſurrounding ſoft parts. The foregoing ſymptoms, which would ſubſide almoſt of themſelves after the fracture has been ſet, might, under the uſe of poultices and fomentations, conſume ſo much time, that, on an attempt being afterwards made to ſet the fracture, the bone would be found already united in its deformed poſition, and all change for the better now impracticable.

The general cuſtom of ſurgeons in this country is to apply the power of extenſion to the lower portion of the broken bone, and that of counter-extenſion to the upper piece; and when the ſtrongeſt muſcles, concerned in diſplacing the fracture, have been relaxed, the hands of the ſurgeon, ſometimes aided by thoſe of an aſſiſtant, uſually ſuffice for making ſuch extenſion and counter-extenſion as is neceſſary for putting the ends of the fracture into as even a ſtate of coaptation as the nature of the caſe will allow.

In France, the moſt diſtinguiſhed ſurgeons, like Deſault and Boyer, make the requiſite degree of extenſion and counter-extenſion in a manner very different from that which is adopted by Engliſh practitioners. Theſe foreign ſurgeons object to our method, that it is often difficult to take hold of the upper and lower portions of a fractured bone, and ſometimes quite impoſſible, as when the neck of the thigh-bone is broken; and that applying the force immediately upon the muſcles which ſurround the fracture irritates them, and makes them enter into violent and ſpaſmodic contractions. Hence, Deſault and Boyer adviſe the extenſion to be made on the lower part of the limb, or on the bone which articulates with the lower piece of the fracture, while the counter-extenſion is to be made on the bone which articulates with the upper piece. For example, in the caſe of a broken leg, they recommend the extending power to act on the foot, and the counter-extending on the thigh; and in the inſtance of a fractured thigh, they adviſe ſuch powers to operate on the leg and pelvis.

In regard to the choice of theſe methods, we have to remark, that as, in this country, moſt fractured limbs are placed in the bent poſition, in order to be ſet and united, the French mode of making extenſion and counter-extenſion is quite inadmiſſible, becauſe the direction of the bones, above and below the fractured one, is, in ſuch poſition, quite different from that of the latter.

We ſhall now ſuppoſe coaptation performed, and the ends of the fracture placed together in as ſmooth a manner as poſſible. The next indication is to keep them quietly in this poſition, until they have acquired a firm union to each other. This object is generally much more difficult of accompliſhment than ſetting the bone; for the muſcles have a continual tendency to draw the ends of the fracture aſunder again: and when ſuch muſcles are ſtrong and numerous, the fracture oblique, and the patient very much troubled with involuntary ſpaſms, all the care and ſkill of the moſt conſummate ſurgeon will ſometimes hardly avail in making the extremities of the fracture grow together, without ſome degree of deformity.

For the purpoſe of preventing the ends of the fracture from changing their poſition, it is not enough to put the limb in ſuch poſture as tends to relax the muſcles, which have the greateſt power in diſturbing the coaptation; for, in general, no poſture can poſſibly be choſen which will incapacitate every muſcle connected with the broken bone. Beſides, whatever poſition we chooſe, the weight of the limb will gradually occaſion a material alteration in it, unleſs care be taken to lay the fracture on a bed which is not liable to yield much. Indeed, it is greatly to be lamented that, in all our public hoſpitals, there ſhould be no beds expreſsly allotted to patients with broken limbs. As Boyer, Deſault, and others, have inſiſted on, the horizontal ſupport, given to a fractured leg or thigh, ought to be capable of making conſiderable reſiſtance, without being hard enough, however, to create any uneaſineſs or pain. Hence, a mattreſs of hair ſeems preferable to one made of wool, or feathers; which ſubſtances are too ſoft, and conſequently yield to the weight of the limb. The good effects of a favourable poſture are to be aſſiſted with the mechanical ſupport derived from an apparatus, which uſually conſiſts of a piece of plaſter, ſome kind of bandage, pads and compreſſes, and long, flat, broad pieces of wood or tin, called ſplints.

With regard to the *application of medicaments*, in caſes of ſimple fractures, a piece of plaſter, compoſed of the ſoap-cerate, ſeems now to have obtained the univerſal approbation of all the beſt ſurgeons of the preſent day. It was firſt brought into general uſe by that diſtinguiſhed ſurgeon Mr. Pott, who recommended it, in his remarks on fractures, in preference to adheſive plaſters, which formerly were ſometimes applied. "The adheſive plaſter," ſays this author,

" muſt for ever be wrong upon any rational principle. The intention, in applying any kind of external medicine to a broken limb, is, or ought to be, to repreſs inflammation; to diſperſe extravaſated blood; to keep the ſkin lax, moiſt, and perſpirable; and, at the ſame time, to afford ſome, though a very ſmall, degree of reſtraint or confinement to the fracture, but not to bind or preſs; and it ſhould alſo be calculated, as much as poſſible, to prevent itching, an herpetic eruption, or an eryſipelatous efflorescence. Adheſive plaſters of all kinds, let the compoſition of them be what it may, are, from this one quality, the leaſt likely to contribute to any of the good ends propoſed; and the moſt likely to be the cauſe of the contrary inconveniences, which ought moſt carefully to be avoided. They obſtruct perſpiration, they heat the ſkin, they produce itching, eruption, and inflammation; and if the fracture be quite ſurrounded by them, and the limb be from any cauſe ever ſo little inclined to ſwell, they make a tight, painful, and pernicious ſtricture, much greater even than a roller, and leſs likely to relax." Mr. Pott next proceeds to recommend the ſoapcerate plaſter, which, he obſerves, lies very eaſy, repels inflammation, is not adherent, comes off clean, and very ſeldom, if ever, irritates or cauſes either herpes or eryſipelas.

The next practical maxim which this writer urged was, that whatever application be made to the fracture, it ſhould be put on in ſuch a manner as will allow it to be renewed and ſhifted, as often as neceſſary, without moving the limb in the leaſt. He inſiſted, that when once a broken thigh or leg has been put to rights, and has been properly depoſited in an eligible ſituation, it ought never to be lifted up, or moved from it again, without neceſſity, until the fracture is perfectly united; and ſuch neceſſity will not very often occur. The frequent motion of a fractured limb cannot poſſibly contribute to the patient's eaſe; nor will any one contend, that when a broken limb has been once depoſited in the beſt poſition poſſible, that ſuch poſition can be mended, merely by taking ſuch limb up and laying it down again.

Theſe facts led Mr. Pott to condemn the employment of any kind of apparatus, which could not be taken off without diſturbing the fracture; and hence he reprobated the plan of applying a common roller to broken legs, which ſort of bandage ſtood in need of being removed and put on afreſh every three or four days; which could never be done, without lifting up the limb from the ſplint and pad on which it was depoſited.

Deligation, as it was termed, is another part of the treatment of fractures in general. The ancients, and the majority of practitioners up to the time of Pott, uſed to apply what is commonly called a roller, which was of different lengths, or ſometimes conſiſted of one, two, or more pieces. Hippocrates was in the habit of employing three; Celſus, ſix; and later ſurgeons, one. Mr. Pott remarks, that, by ſuch kind of bandage, three intentions were formerly aimed at; *viz.* to confine the fracture, to repreſs or prevent a flux of humours, and to regulate the callus. However, though this author acknowledges that ſome ſort of bandage is neceſſary in every ſimple fracture, as well for preſerving ſome degree of ſteadineſs in the limb as for the retention of the applications, yet neither of theſe ends can be anſwered merely, or even principally, by bandage of any kind whatever. Hence Mr. Pott contends, that if every ſort of deligation cannot be a principal, but only an acceſſorial kind of aſſiſtance, very little to be depended upon, ſuch kind of bandage as is moſt difficult to be applied with juſtneſs and exactitude, ſuch as is ſooneſt relaxed and out of order, ſuch as ſtands moſt frequently in need of renewal, and, in ſuch renewal, is moſt likely to give pain and trouble, muſt be more improper and leſs eligible than one which is more eaſily applied, leſs liable to be out of order, and which can be adjuſted without moving the limb.

The *degree of ſupport and ſteadineſs*, communicated to a fractured limb by a linen roller, muſt obviouſly be very trivial. The old idea, alſo, of *preventing a flux of humours*, by means of the bandage, was entirely erroneous. If, ſays Mr. Pott, by the points and edges of the broken bone the muſcles and other ſoft parts be unavoidably wounded and torn; or, if the ſame kind of miſchief be incurred by the inadvertence or indiſcretion of the patient, or of thoſe who aſſiſted in getting him home, or from the violence uſed in extending the limb and ſetting the fracture, inflammation muſt be excited, and pain and tumefaction will be the conſequence; and theſe will continue for ſome time in every fracture; but their duration will be longer or ſhorter, in different caſes, and under different circumſtances. Evacuation, reſt, and a favourable poſition of the limb, will, and do in general, remove all theſe complaints. Bandages, however, can do nothing more, in bringing about this benefit, than keep the applications in their proper place: on the contrary, if the bandage be a roller, it muſt, by the frequent neceſſity of its being adjuſted, and the frequent motion of the limb, in ſome degree counteract the proper intention of cure.

The third purpoſe for which the roller was formerly applied was the *regulation and reſtraint of the callus*. The old ſurgeons uſed to look upon callus as a particular juice always ready to ooze from the ends of fractures, for the purpoſe, as it were, of ſoldering them together; but it was imagined that, unleſs ſuch callus was reſtrained by art, it would always flow in ſuch quantity as to create trouble and deformity. This gelatinous kind of fluid is undoubtedly the medium by which fractures are united; but, Mr. Pott very ably explains, that art is by no means capable of managing it. He admits, that the callus does oftentimes create tumefaction and deformity, or even lameneſs; but, he contends, that the fault, in theſe caſes, does not lie in the mere redundance of ſuch juice: it is derived from the nature of the fracture, from the inequality of it when ſet, and from the inapt poſition of the broken ends, with regard to each other; nor is ſurgery, nor the ſurgeon, any otherwiſe blameable in this caſe than as it was, or was not, originally in their power to have placed them better. The inequality of the fracture occaſions the ſeeming redundance of callus, and the ſwelling in the place of the union. Mr. Pott obſerves, that when a bone has been broken tranſverſely, or nearly ſo, and its inequalities are therefore neither many nor great; that when ſuch broken parts have been properly ſet, and proper methods uſed to keep them conſtantly and ſteadily in ſuch ſtate, the divided parts unite by the intervention of a gelatinous effuſion, which is gradually converted into new bone. The place where the union has taken place is very little perceptible, and cauſes no deformity nor inconvenience. But, when a bone has been broken very obliquely, or very unequally; when the parts of a fracture are ſo circumſtanced as not to admit of exact coaptation; when ſuch exact coaptation, as the fracture perhaps would have admitted, has not been judiciouſly made; when from unmanageableneſs, inadvertence, or ſpaſm, the proper poſition of the limb has not been attended to, or preſerved: in all ſuch caſes, there muſt be conſiderable inequality of ſurface; there muſt be riſings on one ſide, and depreſſions on another; and the callus cannot unite the parts in the ſame time, or in the ſame way, as when the fracture is tranſverſe, and evenly ſet. The deformity will be proportioned to the greater or leſſer exacti-

tude

tude with which the fracture is put in a ſtate of coaptation; the moſt diſfigurement happening when the fracture is not ſet at all, that is, when the broken ends of the bone unite by touching each other's ſides.

Mr. Pott concludes this part of the ſubject with remarking, that this doctrine of callus, conſidered as a particular kind of juice, and as being liable to great redundance, if not prevented by art, has not only miſled many people, but has often been made uſe of as a cover to ignorance and neglect. When lameneſs and deformity have been the conſequences of one or both theſe cauſes, more than of the nature and circumſtances of a fracture, the callus has been found ready at hand to take the blame; and the ideal exuberance of this cement has often been urged as an excuſe for real want of knowledge, or for groſs neglect.

Inſtead of a common roller, all ſurgeons now employ, for ſimple fractures of the leg and thigh, what is uſually termed the eighteen-tailed bandage. In general, the pieces which are to ſurround the limb are ſo arranged as to form a right angle with the piece which runs along under the member. However, Mr. Pott adviſes us to tack on the croſs-pieces, ſo as to make an acute angle; by which means they will fold over each other in an oblique direction, ſit more neatly and more ſecurely, and have more connection with, and more dependence on, each other. The eighteen-tailed bandage was uſed for compound fractures ſome time before its application was extended to ſimple ones. In the firſt inſtances, ſurgeons were ſtruck with the advantage of not being obliged to lift up and diſturb the limb every time it was dreſſed, and every time the bandage became ſlack. As Mr. Pott remarks, the pain attending motion in a compound fracture, and the circumſtances of the wound, are certainly very good reaſons for dreſſing ſuch wound with a bandage, which does not render motion neceſſary: but, he aſks, what can make it right to move a limb, in the caſe of ſimple fracture? When a broken bone has been well ſet, and the limb well placed, no good can ariſe from moving it; but conſiderable miſchief may be occaſioned by the diſturbance. Perfect quietude is as neceſſary towards the union of a bone in a ſimple as in a compound fracture. In the latter caſe, there is a wound which requires to be dreſſed, and motion may excite rather more pain than in the former; but, notwithſtanding this, motion is alſo highly prejudicial in the caſe of a ſimple fracture. Mr. Pott has explained, that every benefit, which can be ſuppoſed to be obtained by the common roller, is equally attainable from the uſe of the eighteen-tailed bandage, with one additional, and, to the patient, moſt invaluable advantage, *viz.* that of never finding it neceſſary to have his leg or thigh, once during the treatment, moved from the pad on which it has been laid.

The reader muſt not infer from the foregoing obſervations, that a common roller is never eligible for ſimple fractures on the contrary, it is always preferred for fractures of the arm, and generally alſo for thoſe of the fore-arm.

The next parts of the apparatus for fractures are the ſplints, which are uſually made of wood, tin, or paſteboard, and are applied length-ways on the broken limb. In fractures of the arm and thigh ſurgeons generally make uſe of four; in thoſe of the leg and fore-arm, two. As the deſign of ſplints is to communicate to the limb, for a certain time, ſteadineſs and inflexibility, it is obvious that they ſhould always be formed of ſuch materials as are ſufficiently firm and unyielding.

The old ſurgeons uſed to err conſiderably in the application of ſplints, only employing ſuch as were ſo ſhort, that they merely extended a little way above and below the fracture, without reaching to either of the neighbouring joints. In this manner of application, and of this ſize, as Mr. Pott has remarked, ſplints are in fact neither more nor leſs than compreſſes, and compreſſes made of very bad materials. All the good that ever is or that can be done by them, when of ſuch length, and ſo applied, might certainly be done in a better manner by a more proper kind of compreſs; and every diſadvantage which a hard reſiſting compreſs, injudiciouſly applied, is capable of producing, is probable to reſult from them thus uſed.

The ſame author explains, that the true and proper uſe of ſplints is to preſerve ſteadineſs in the whole limb, without compreſſing the fracture at all. By the firſt effect, they become very aſſiſtant to the curative intention; by the ſecond, they are very capable of cauſing pain and other inconveniences, at the ſame time that they cannot, in the nature of things, contribute to the ſteadineſs of the limb. In the caſe of a broken leg, the ſplints ſhould be long enough to reach above the knee, and below the ankle; and, in all inſtances, they ſhould be hindered from making painful preſſure on any part of the limb, by lining them with pads, well ſtuffed with tow, wool, or any ſoft ſubſtance.

When the thigh-bone is fractured, if the limb is laid in the ſtraight poſition, one ſplint ſhould reach from the hip to the outer ankle, and another from the groin to the inner ankle.

The proper *poſition* in which fractured limbs ſhould remain, during the cure, would be our next ſubject for conſideration, were we not induced to defer what we have to ſay on this point till we treat of particular fractures.

With reſpect to the *prevention and relief of accidents*, the chief ſymptoms which the ſurgeon has to counteract are inflammation and ſwelling of the limb. In order to avert theſe complaints, the moſt effectual plan, as the reader muſt already underſtand, is, after ſetting the fracture, to keep it completely motionleſs, until it has become firmly united. That all diſturbance of the rough, ſharp extremities of a recently broken bone muſt irritate and do great miſchief to the ſurrounding ſoft parts, is a truth ſo manifeſt as to need no comment.

When the ſurgeon, on his firſt arriving in the patient's chamber, finds the limb not merely fractured, but conſiderably bruiſed; or when, after a day or two, great ſwelling and inflammation come on; the moſt proper practice is to wet the bandage with the ſaturnine lotion, and place folded linen, wet with the ſame application, under the upper pad and ſplint. It will not be neceſſary to take off the ſplint every time more of the lotion is to be applied: it will be quite enough to ſqueeze ſome of the fluid out of a ſponge into the interſpace between the ſplints; by which means, the bandage and linen will be kept conſtantly wet, and an inceſſant evaporation from the limb maintained. When a good deal of ecchymoſis prevails, a lotion compoſed of vinegar, ſpirit of wine, and muriate of ammonia, is the moſt efficacious in promoting the abſorption of the extravaſated blood. We need hardly obſerve, that when it is deemed proper to apply a lotion, the emplaſtrum ſaponis becomes ſuperfluous.

Patients with fractured limbs ſhould be kept on a low regimen, for the firſt few days, unleſs extreme old age or great debility ſhould forbid; but, after the hazard of inflammation is over, a nouriſhing diet is to be recommended, as a certain vigour in the circulation, and ſtrength of conſtitution, greatly expedite the proceſs by which broken bones unite.

In ſome patients who have fractured limbs, the ſwelling and inflammatory ſymptoms are ſo conſiderable, that prudence dictates the propriety of taking away blood. The

neceſſity of ſuch practice particularly occurs when the bone has been broken with great violence, and the patient is ſtrong, robuſt, and of a plethoric habit.

Another invariable indication, throughout the treatment of all fractures, is to keep the bowels in a regular ſtate; for coſtiveneſs is very apt to reſult from the degree of confinement to which the patient is unavoidably ſubjected.

The ſurgeons ſhould never forget to preſcribe opium, in all caſes of fractures attended with ſevere pain, violent ſpaſms, loſs of ſleep, &c.

When an artery of a certain magnitude happens to be wounded by the ſharp point of a fractured bone, and a conſiderable quantity of blood is effuſed in the cellular membrane, it may be indiſpenſably neceſſary to cut down to the veſſel, and tie it with two ligatures, one above, the other below the laceration in it. J. L. Petit mentions an inſtance, in which an aneuriſm was produced by a wound of the anterior tibial artery, in the caſe of a broken leg.

With regard to the proceſs by which fractures unite, it is not very diſſimilar from that by which wounds in ſoft parts are healed. The veſſels of the broken ſurfaces of the bone, very ſoon after the accident, pour out coagulated lymph. Into this lymph either the neighbouring veſſels ſhoot, or in it new ones are in ſome inexplicable way or another generated. The veſſels, in a certain time, acquire the power of ſecreting lime, and thus convert the coagulating lymph into new bone, or callus, which, from being at firſt as flexible as cartilage, gradually aſſumes all the firmneſs, inflexibility, and other qualities of original bone. Some perſons, when they ſee a broken limb raiſed from the ſplints, at the end of about a fortnight, are apprehenſive leſt the bones ſhould ſnap again; but, though they may be obſerved to bend, they do not break, which laſt evil is generally prevented by the great flexibility of the callus in the early ſtate of its formation.

Surgeons occaſionally meet with patients in whom there ſeems to be no power of forming callus, ſo that fractures cannot unite. The cauſe of this peculiarity, as far as we have been able to learn, ſeems to be involved in obſcurity, and probably will never be well underſtood. It is not one kind of conſtitution in which ſome impediment to the generation of callus prevails; for we ourſelves have ſeen fractures remain diſunited in perſons of very different temperaments, notwithſtanding the greateſt care was taken, and the utmoſt ſkill exerted to procure an union. We have ſeen an inſtance in which a ſtrong, healthy, muſcular young man broke the os brachii, ſomewhere about the inſertion of the deltoid muſcle; but, notwithſtanding every poſſible attention, ſuch fracture never united, and was at length converted into a kind of joint. This patient ſubmitted to have the ends of the fracture cut down to, and fairly ſawn off, but, though the limb was a ſecond time carefully kept in ſplints and a ſling, no union enſued. The only remarkable particularity about this man was a great indifference to pain.

We have alſo met with a very hypochondriacal patient, a man about two or three and thirty years old, in whom a fracture of the tibia and fibula did not unite till after a very conſiderable ſpace of time, not leſs than four months.

There was likewiſe, at the latter end of the year 1808, in St. Bartholomew's hoſpital, a woman, whoſe fractured os brachii remained diſunited for ſeveral months, though particular attention was paid to her. It happened, that while ſhe was under ſir James Earle ſhe was ſeized with ſome illneſs, of which ſhe died. The arm was now carefully examined, in order to ſee whether any cauſe could be diſcovered for the want of union in the fracture; and, on making an inciſion into the limb, the upper ſharp end of the lower portion of the broken bone was found conſiderably drawn upward, and ſtuck in the ſubſtance of the biceps muſcle. This circumſtance will at once account for the exceſſive pain which the woman ſuffered whenever her arm was moved, and explains why no union took place in the fracture, the extremities of which were not at all in contact. We are not, however, to conſider this cauſe as a general one, which prevents the union of fractures; for in moſt inſtances the ends of the bone are known to touch each other fairly, and to be in the proper poſition for uniting.

We have already recorded the failure of one operation, which was performed with a view of making a broken arm unite; and, though ſeveral attempts of the ſame kind have been made by eminent ſurgeons, they have all failed. Hence, at preſent, little encouragement is held out for perſevering in a proceeding which is attended with ſome conſiderable danger, and a vaſt deal of pain, as any one may readily conceive, who reflects on what ſevere ſteps muſt be taken in order to cut down to, turn out, and ſaw off the extremities of ſuch fractures as intereſt the arm, the thigh, or the leg.

Compound Fractures.

We have already ſtated that, in the language of ſurgery, a *compound* fracture denotes one which is complicated with a wound in the integuments, which wound is generally occaſioned by a protruſion of one of the ſharp ends of the broken bone, and of courſe leads down to, and communicates with, the fracture.

The circumſtance of there being this ſort of injury done to the ſkin makes a very material difference in the nature of the caſe, ſince it increaſes the danger in a manner which is always a ſource of alarm to practitioners of the greateſt profeſſional judgment and moſt extenſive experience. It is not, however, every wound which may happen to attend a fracture, that can occaſion the conſiderable augmentation of danger to which we have alluded. The ſame violence which breaks the leg or the arm may cut, or lacerate, at the ſame time, ſome portion of the ſkin and muſcles, more or leſs diſtant from the fracture; but, provided ſuch miſchief done to the ſoft parts is not of itſelf perilous from its extent or other circumſtances, it does not produce any ſerious aggravation of the ſymptoms likely to ariſe from the fracture.

The increaſed danger of a compound fracture eſſentially depends on the circumſtance of there being conjoined with the breach of continuity in the bone *ſuch a wound as makes an external opening into the fracture.*

According to Mr. Pott, the firſt object of conſideration in compound fractures is, "whether the preſervation of the fractured limb can, with ſafety to the patient's life, be attempted; or, in other words, whether the probable chance of deſtruction, from the nature and circumſtances of the accident, is not greater than it would be from the operation of amputation. Many things may occur to make this the caſe. The bone or bones being broken into many different pieces, and that for a conſiderable extent, as happens from broad wheels or other heavy bodies of large ſurface, paſſing over or falling on ſuch limbs; the ſkin, muſcles, tendons, &c. being ſo torn, lacerated, and deſtroyed, as to render gangrene and mortification the moſt probable and immediate conſequence; the extremities of the bones forming a joint, being cruſhed, or, as it were, comminuted; and the ligaments connecting ſuch bones being torn and ſpoiled; are, among others, ſufficient reaſons for propoſing and for performing immediate amputation: reaſons which, notwithſtanding any thing that may have been ſaid to the contrary, long and reiterated experience has approved, and which are vindicable upon every principle of humanity or chirurgic knowledge.

"When

" When a ſurgeon ſays, that a limb, which has juſt ſuffered a particular kind of compound fracture, ought rather to be immediately cut off than that any attempt ſhould be made for its preſervation, he does not mean, by ſo ſaying, that it is abſolutely impoſſible for ſuch limb to be preſerved at all events; he is not to be ſuppoſed to mean ſo much in general, though ſometimes even that will be obvious; all that he can truly and juſtly mean is, that from the experience of all time, it has been found that the attempts to preſerve limbs ſo circumſtanced have moſt frequently been fruſtrated by the death of the patients in conſequence of ſuch injury; and that from the ſame experience, it has been found that the chance of death from amputation is by no means equal to that ariſing from ſuch kind of fracture.

" Every man knows that apparently deſperate caſes are ſometimes cured; and that limbs ſo ſhattered and wounded as to render amputation the only *probable* means for the preſervation of life, are now and then ſaved. This is an uncontroverted fact, but a fact which proves very little againſt the common opinion; becauſe every man of experience alſo knows that ſuch eſcapes are very rare, much too rare to admit of being made precedents, and that the majority of ſuch attempts fail.

" This conſideration relative to amputation is of the more importance, becauſe it moſt frequently requires immediate determination; every minute of delay is, in many inſtances, to the patient's diſadvantage; and a very ſhort ſpace of time indeed frequently makes all the difference between probable ſafety and fatality. If theſe caſes in general would admit of deliberation for two or three days, and during that time ſuch circumſtances might be expected to ariſe as ought neceſſarily to determine the ſurgeon in his conduct, without adding to the patient's hazard, the difference would be conſiderable; the former would not ſeem to be ſo precipitate in his determination as he is frequently thought to be, and the latter being more convinced of the neceſſity, would ſubmit to it with leſs reluctance. But, unhappily for both parties, this is ſeldom the caſe; and the firſt opportunity having been neglected, or not embraced, we are very frequently denied another. Here, therefore, the whole exertion of a man's judgment is required, that he may neither raſhly and unneceſſarily deprive a patient of a limb, nor, through a falſe tenderneſs and timidity, ſuffer him to periſh by endeavouring to preſerve ſuch limb. Some degree of addreſs is alſo neceſſary upon ſuch occaſion, in order to convince the patient that what ſeems to be determined upon haſtily and with precipitation, will not ſafely admit of longer delay."

Mr. Pott next enters into ſome obſervations relative to the treatment, when it is judged prudent to endeavour to ſave the limb, and he explains, that the firſt object is the reduction of the fracture. He obſerves, that if the bone be not protruded forth, the trouble of reducing and of placing the fracture in a good poſition will be much leſs than if the caſe be otherwiſe; and that, when the bone is protruded, the difficulty is always in proportion to the comparative ſize of the wound through which ſuch bone has paſſed. In a compound fracture of the leg or thigh, it is always the upper part of the broken bone which is thruſt forth. If the fracture be of the tranſverſe kind, and the wound large, a moderate degree of extenſion will in general eaſily reduce it; but, if the fracture be oblique, and terminates, as it often does, in a long ſharp point, this point very often makes its way through a wound only juſt large enough to permit ſuch extenſion. In this inſtance the very placing of the leg in a ſtraight poſition, in order to make extenſion, obliges the wound or orifice to gird the bone tight, and makes all that part of it which is out of ſuch wound preſs hard on the ſkin of the leg underneath it. In theſe circumſtances, (continues Mr. Pott,) all attempts at reduction in this manner will be found to be impracticable; the more the leg is ſtretched out, the more tightly will the bone be begirt by the wound, and the more will it preſs on the ſkin underneath.

The above eminent ſurgical author next cenſures the method not unuſually reſorted to in this caſe, of ſawing off a piece of the protruded bone. He does not, however, condemn ſuch a proceeding as always or abſolutely unneceſſary or wrong, but, as being ſo in moſt inſtances. In ſome few caſes, and when the end of the bone is exceedingly ſharp, he acknowledges the utility of having recourſe to the ſaw.

Mr. Pott ſtates that the two moſt proper means of overcoming the impediment to the reduction are change of poſture of the limb, and enlargement of the wound. He ſays that, in many caſes, the former of theſe, under proper conduct, will be found fully ſufficient, and that when it fails, the latter ſhould always be made uſe of. The poſition of the limb which this author adviſes to be adopted is the bent one, in which he conceived the muſcles were relaxed, and the bone was leſs begirt by the wound.

When the projecting end of the fracture cannot be reduced, with the aid of a favourable poſition and proper extenſion, it becomes neceſſary to make an enlargement of the wound. This operation, according to Mr. Pott, is free from danger, the ſkin being the only part requiring to be cut.

When the bone is broken into ſeveral pieces, and any of them are either totally ſeparated, ſo as to lie looſe in the wound, or ſo detached as to render their union highly improbable, all ſuch pieces ought to be taken away; but Mr. Pott very properly recommends them to be removed with all poſſible gentleneſs, without pain, violence, or laceration, without the riſk of hemorrhage, and with as little poking into the wound as poſſible. Any ſharp, irritating points of bone on the end of the fracture ſhould alſo be removed. This part of the treatment ought to be executed with great caution; for, as the foregoing ſurgeon judiciouſly remarks, if the parts ſurrounding the fracture be violated, that is, be torn, irritated, and ſo diſturbed as to excite great pain, high inflammation, &c. it is exactly the ſame thing to the patient, and to the event of the caſe, whether ſuch violence be the neceſſary conſequence of the fracture, or of the unneceſſary and awkward manner of poking into, and diſturbing the wound.

In the reduction of a compound fracture, the indication is the ſame as in a ſimple one, *viz.* by means of a proper degree of extenſion to obtain as apt a poſition of the ends of the fracture with regard to each other as the nature of the caſe will admit, and thereby to produce as perfect and as ſpeedy an union as poſſible. Attention alſo to the relaxation of ſuch muſcles as have the greateſt power to impede and diſturb the coaptation is here equally proper.

The wound being dilated, if neceſſary; looſe pieces of bone removed, if there were any; and the fracture reduced and placed in the beſt poſſible poſition; the next thing, as Mr. Pott remarks, is to dreſs the wound.

We have already ſtated, that the principal part of the additional danger attendant on a compound fracture ariſes from the circumſtance of there being a wound which communicates with the injured part of the bone. Provided the ſurgeon can ſucceed in uniting ſuch wound by the firſt intention (and this ſucceſs may often be obtained), a vaſt deal of the peril is at once removed, and the caſe is, as it were, all on a ſudden converted into one partaking of the more mild nature of a ſimple fracture. Hence, inſtead of dry lint and a pledget, which Mr. Pott recommends to be applied alone,

the

the moſt eminent ſurgeons in London now employ ſtrips of adheſive plaſter, with which they cloſe the wound, keep its edges accurately in contact, and give it an opportunity of uniting by adheſion. In ſhort, the dreſſings are to be the ſame as thoſe commonly uſed for healing recent inciſed wounds, *viz.* adheſive plaſter, with as much or little plain lint as may ſeem proper, and whatever pledget of ſimple ointment the practitioner may chooſe.

It muſt be obvious, however, that ſince the wound of a compound fracture is produced in a rough, violent manner, by a protruſion of the end of the bone, union by the firſt intention cannot take place ſo frequently as in wounds made with a ſharp cutting inſtrument. But though it be true, that the attempt fails more often than it ſucceeds, yet the practice is not at all the leſs commendable, for it is productive of no harm, is ſometimes attended with an union of ſome part of the wound, when not with the whole, and always affords the patient his chance of ſpeedily eluding the alarming ſymptoms always apt to accompany a fractured limb, having a wound leading down to the breach of continuity in the bone. The degree of ſuch chance will always be greater, in proportion as the wounded part has ſuffered leſs of any kind of miſchief, in addition to the mere diviſion of the fibres. When the fleſh has been much torn and bruiſed, beſides being divided, the probability of the wound healing by adheſion is conſiderably diminiſhed.

Sometimes the wound may preſent ſo ragged, contuſed, and lacerated an appearance, that any man of the leaſt experience would be able to foreſee, that inſtead of union by the firſt intention, ſloughing muſt enſue. Perhaps in a few caſes of this deſcription it might be as well to give up the employment of adheſive plaſters, and have recourſe at once to the mildeſt emollient applications under the ſplints.

It too frequently happens, that the wound of a compound fracture ſuppurates ſo that it can only be healed by granulations. In this ſtate dry lint, and a pledget of any ſimple ointment, are the moſt eligible dreſſings; but others may be indicated in the progreſs of the caſe according as the aſpect and appearance of the ſore undergo changes. The lint ſhould be laid on lightly, be of the ſofteſt kind, and only in ſufficient quantity to abſorb the diſcharge. It ſhould never be crammed into the wound, nor be ſo applied as to prevent the exit of the matter. "The times of dreſſing," (ſays Pott,) "muſt be determined by the nature of the caſe; if the diſcharge be ſmall or moderate, once in twenty-four hours will be ſufficient; but if it be large, more frequent dreſſing will be neceſſary, as well to prevent offence, as to remedy the inconveniences ariſing from a great diſcharge of an irritating, ſharp ſanies."

Mr. Pott diſapproved of the general plan of enveloping compound fractures from the very firſt in ſoft, warm, relaxing poultices, which, he thought, ought only to be uſed when the limb is actually in a tenſe, ſwollen, and painful ſtate. When the parts were not in this ſituation, he was of opinion, that the prevention of inflammation formed the grand indication, for which object he adviſed the employment of diſcutient applications, ſuch as mixtures of ſpirit of wine, vinegar and water with ſal ammoniac, the aqua ammoniæ acetatæ, aqua lithargyri acetati, and medicines of this claſs, in whatever form the ſurgeon might prefer.

Theſe latter remedies were to be aſſiſted with the uſual antiphlogiſtic means, particularly phlebotomy. With regard to bleeding, in caſes of compound fractures, we have to obſerve, that although it appears to have the authority of Pott in its favour, all the moſt celebrated ſurgeons now agree, that patients in large cities and hoſpitals will not bear this evacuation. In country practice, however, circumſtances are different, and veneſection may be performed, and that repeatedly, not only with ſafety, but with the moſt ſtriking advantage. When a patient who has met with a bad compound fracture of the leg happens to be in London, and eſpecially if he is alſo in an hoſpital there, the loſs of blood by the lancet too often makes him totally incapable of bearing the long and copious diſcharge which frequently enſues, and brings him into the extreme ſtate of debility.

Compound fractures ought generally to be dreſſed every day when they are in a ſuppurating ſtate. In doing this, the limb ſhould not be moved in the leaſt, or only ſuffer ſuch diſturbance as is utterly unavoidable. Surgeons have long been acquainted with the ſuperior advantage of the eighteen-tailed bandage in theſe inſtances, although it was not till the time of Pott that it came into common uſe for ſimple fractures. The reader already knows that its great recommendation is the manner in which it admits of being opened, ſo as to allow the limb to be looked at without the ſmalleſt motion of the fractured part.

The obſervations, which have been made on the ſubject of ſplints, and the poſition of the limb, in our general remarks on fractures, are all applicable here.

Of all caſes, compound fractures require at firſt the moſt rigid obſervance of the antiphlogiſtic regimen. As Mr. Pott ſtates, pain is to be appeaſed, and reſt obtained by anodynes; inflammation is to be prevented or removed by free and frequent bleeding (out of large cities and hoſpitals), by keeping the body open, and by the adminiſtration of ſuch medicines as are beſt known to ſerve ſuch purpoſes. In this firſt ſtage alſo, the treatment of the limb muſt be calculated either for the prevention of inflammatory tumefaction, by diſcutient applications, or for the removal of ſwelling and tenſion, when they have already come on, by fomentations and emollient remedies.

When the foregoing mode of treatment ſucceeds, the wound either unites by the firſt intention, heals in a quiet manner with an inconſiderable degree of ſuppuration, or elſe it is at firſt attended with great and extenſive inflammation, which leads to the formation of large abſceſſes and lodgments of matter. When the attempts of the ſurgeon fail, the limb is ſeized with mortification.

If the wound heals favourably, the ſurgeon has only to avoid doing miſchief, either by his manner of dreſſing, or by diſturbing the limb. Mr. Pott obſerves that nature unmoleſted will accompliſh her own purpoſe, and art has little more to do, than preſerve the due poſition of the injured part.

When large quantities of matter form and lodge, the utmoſt exertion of the judgment will ſometimes be neceſſary in the treatment of the caſe. "Enlargement of the preſent wound, for the more convenient diſcharge of matter, new or counter-openings, for the ſame purpoſe, or for the extraction of fragments of broken or exfoliated bone, will very frequently be found neceſſary, and muſt be executed." Mr. Pott expreſſes his preference of a counter-opening to a compreſs, which has occaſionally been uſed, with a view of preventing the lodgment of matter, and which ſometimes acts diametrically oppoſite to the intention with which it is uſed, beſides requiring more preſſure to make it efficacious than a limb, in ſuch circumſtances, can generally bear.

While the firſt or inflammatory ſtage of a compound fracture laſts, and large abſceſſes have not taken place, the antiphlogiſtic treatment is indicated. No ſooner has ſuppuration occurred, and extenſive collections of matter formed, than all evacuations ſhould be diſcontinued, and the patient's ſtrength be ſupported with all poſſible aſſiſtance from diet and medicines.

The

The detention and irritation of a ſplinter of bone have been known to keep up a large, diſagreeable diſcharge for a conſiderable length of time. Mr. Pott obſerves, that if ſuch diſcharge be made, and there be neither ſinus nor lodgment to account for it, and all other circumſtances are favourable, an examination ſhould always be made, in order to know whether ſuch cauſe does not exiſt, and if it does, it muſt be gently and carefully removed.

In caſes of bad compound fractures, attended with a great deal of ſuppuration, the diſcharge ſometimes becomes too profuſe for the patient to bear, notwithſtanding the moſt ſkilful treatment, and he is neceſſitated to part with his limb, as the only means of ſaving his life, after undergoing very ſevere ſufferings. In ſpeaking of this ſubject, Mr. Pott has occaſion to remark, that he never had found it neceſſary to amputate a limb for a compound fracture, on account of the profuſe diſcharge, when ſuch fracture was in an united ſtate. Though amputation is ſometimes rendered indiſpenſable in ſpite of the beſt treatment, yet this eminent ſurgeon was convinced, that the neceſſity for ſo ſevere a proceeding was occaſionally produced by reducing the patient too much. On finding all febrile complaint at an end, all inflammatory tumour and hardneſs gone, the patient rather languid than feveriſh, the pulſe rather weak and low, than hard and full, the appetite fail, an inclination to ſweat and be purged, without aſſignable cauſe, and this in conſequence of a large diſcharge of matter from a limb, which has ſuffered great inflammation, but which has now become rather ſoft and flabby than hard and tumid, we are recommended to ſupport the patient *totis viribus*.

When an endeavour is made to ſave a limb, which has ſuffered a compound fracture, and the attempt fails from the very firſt, gangrene and mortification are the conſequences ariſing, ſometimes from the miſchief done to the limb at the time that the bone is broken, ſometimes from the laceration of the parts made by the protruſion of the bone.

Mortification may alſo be occaſioned by improper treatment, ſuch as violent extenſion, irritation of the wounded parts with the probe, painful dreſſings, improper diſpoſition of the limb, and the neglect to give uſeful medicines. Mr. Pott notices that all, or any of theſe cauſes may either induce ſuch a ſtate of inflammation as ſhall end in gangrene, or may permit the inflammation neceſſarily attendant upon the accident, to terminate in the ſame event.

When the mortification is the mere conſequence of the injury done to the limb, Mr. Pott has explained, that it generally makes its appearance very early, and its progreſs is too rapid for art to check. Hence when this kind of diſorder is likely to enſue, no time can be ſpared; the impending miſchief muſt either be ſubmitted to, or prevented by early amputation. A few hours (ſays the above writer) make all the difference between probable ſafety and deſtruction. If we wait till the diſeaſe has taken poſſeſſion of the limb, even in the ſmalleſt degree, the operation will ſerve no purpoſe, but that of accelerating the patient's death. The gangrene always extends higher up the interior, than the ſuperficial part of the limb, and when once begun, it can never be ſtopped by amputation.

Therefore when the firſt opportunity of performing the operation has been neglected, the attempt ſhould not be thought of while the mortification is in a ſpreading ſtate; but the practitioner ſhould now endeavour, by all poſſible means, to aſſiſt nature in ſeparating the dead from the living parts. It is a lamentable truth, however, that in this ſtate of things the patient generally dies, and his life falls a ſacrifice to an injudicious effort to ſave his limb.

When the mortification is not the immediate effect of the miſchief done to the limb by the accident; but is the conſequence of high inflammation, badneſs of general habit, wrong treatment, &c. the progreſs of the diſorder may ſometimes be checked and ſtopped, and the dead parts ſeparated from the living ones, by adopting ſuch means as each particular caſe may require. Inflammation will ſtand in need of antiphlogiſtics, pain and irritation of anodynes, and bark, joined ſometimes with cooling, ſometimes with cordial, medicines will be proper. The external applications ought to conſiſt in fomentations, emollient poultices, and dreſſings of the moſt lenient kind.

But we need not ſpeak further on this part of the ſubject, as whatever more is neceſſary to be known will be explained in other places. See GANGRENE, MORTIFICATION, SPHACELUS.

We ſhall finiſh theſe remarks on compound fractures with a citation from an author, whoſe works abound with the richeſt practical information. "There are three points of time, or three ſtages of a bad compound fracture, in which amputation of the limb may be neceſſary and right, and theſe three points of time are ſo limited, that a good deal of the hazard or ſafety of the operation depends on the obſervance, or non-obſervance of them.

"The firſt is immediately after the accident, before inflammation has taken poſſeſſion of the parts. If this opportunity be neglected, or not embraced, the conſequence is either a gangrene, or a large ſuppuration with formation and lodgment of matter. If the former of theſe be the caſe, the operation ought never to be thought of, till there is a perfect and abſolute ſeparation of the mortified parts. If the latter, no man can poſſibly propoſe the removal of the limb, until it be found, by ſufficient trial, that there is no proſpect of obtaining a cure without, and that by not performing the operation, the patient's ſtrength and life will be exhauſted by the diſcharge. When this becomes the hazard, the ſooner amputation is performed the better. In the firſt inſtance, the operation ought to take place before inflammatory miſchief is incurred; in the ſecond, we are to wait for a kind of criſis of ſuch inflammation; in the third, the proportional ſtrength and ſtate of the patient, compared with the diſcharge and ſtate of the fracture, muſt form our determination." See Pott on Fractures.

Particular Fractures.

Fractures of the Oſſa Naſi.—The ſituation of the oſſa naſi expoſes them very much to external violence; but the manner in which they are implanted between the aſcending proceſſes of the upper maxillary bones, and the way in which they are ſupported by the vomer and os frontis, are reaſons why they are not ſo frequently fractured by blows and falls, as would otherwiſe be the caſe. However, they do ſometimes give way, and become depreſſed and ſeparated from the adjacent bones. Both of them are not always broken at the ſame time. In certain inſtances, one is found fractured all acroſs, while the other is only elevated, or beaten inward, without there being in it any breach of continuity. A fracture of the oſſa naſi is not unfrequently attended with a ſimilar injury of the perpendicular lamellæ of the os ethmoides, in which event, the latter proceſs is invariably driven to one ſide or the other, and may eaſily be moved either with the little finger or a probe introduced into the noſtril. A fracture of the oſſa naſi is often accompanied by ſerious ſymptoms, inflammation of the pituitary membrane, ſwelling of the noſe and face, more or leſs ophthalmy, and occaſionally a bleeding which cannot eaſily be ſtopped. The reſpiration alſo ſometimes ſeems oppreſſed; and when the vio-

lence of the blow has been ſuch as not to have entirely ſpent itſelf on the fracture, but to have extended to the cribriform lamella, the effects of a concuſſion of the brain ſometimes enſue, and even an extravaſation may happen within the cranium, as is proved by the teſtimony of the beſt obſervers. A fracture of the noſe may eaſily be diſtinguiſhed from the very firſt. The diagnoſis, however, is more obſcure when inflammation and ſwelling have taken place; but, upon the whole, we may ſtate that the nature of the accident may always be aſcertained with facility.

The treatment of the caſe conſiſts in replacing the deranged pieces of bone, by means of a probe, or any other ſuitable inſtrument, introduced up the noſtril. Thus the fragments may be moved as far outward as neceſſary, while the ſurgeon, applying the index finger of his left hand externally, endeavours to prevent any preternatural projection. The ſame plan muſt be adopted on both ſides of the noſe, when the two oſſa naſi are fractured at once, and the broken pieces diſplaced. When the ſeptum naſi is thrown out of its due poſition, it muſt be rectified with any convenient inſtrument, care being taken not to paſs ſuch inſtrument too far, or forcibly, upward, for fear of injuring the delicate tranſverſe lamella of the os ethmoides.

Should the efforts of the ſurgeon be interrupted by the patient's ſneezing, it will be neceſſary to wait a little before repeating the attempt.

When the fracture is attended with a wound of the integuments, and the fragments of bone are ſo detached as to leave no hope of their re-union, they ought to be extracted with as much care and as little irritation as poſſible.

When the fracture is ſimple, and not at all diſplaced, the treatment is limited to general means for averting and diminiſhing inflammation.

In other inſtances, in which the pieces of bone ſlip out of their right poſition, the fragments ſhould be ſupported with a bit of hollow bougie, ſurrounded with lint and introduced up the noſtril. Writers alſo recommend, for the ſame purpoſe, a piece of quill cut open at each end and wrapt round with agaric, which, they ſay, tends to check the troubleſome hemorrhage generally attending ſuch caſes. This latter duty agaric may probably fulfil with about as much certainty as lint, which, being always at hand, is therefore to be preferred.

Hollow tubes, of ſome kind or another, are certainly better than the ſolid ſubſtances uſed by Hippocrates, and alſo preferable to the patient's fingers, which the ſame author employed in the majority of inſtances. Foreſtus imitated Guy de Chauliac in adviſing the uſe of cannulæ, on the ground that they both facilitated reſpiration, and aided in keeping the parts from falling inward.

The fragments of the fracture having been replaced, linen wet with the ſaturnine lotion ſhould be applied, and compreſſes laid on each ſide of the face, in the hollow between the cheeks and the noſe. Theſe applications are to be kept in their reſpective places with a roller.

A force, which breaks the oſſa naſi, may alſo beat inward the cribriform lamella and the criſta galli of the os ethmoides, ſo as to occaſion a dangerous degree of preſſure on the brain. When the ſymptoms, and the extent to which the oſſa naſi are depreſſed, lead the ſurgeon to ſuſpect the miſchief which we have juſt now mentioned, an immediate endeavour ſhould be made to draw downward and forward the cribriform lamella and criſta galli, which object might perhaps be moſt conveniently accompliſhed by introducing a pair of ſmall common forceps into each noſtril, and preſſing the two inſtruments together againſt the naſal proceſs of the ethmoid bone, which, by their means, could then be pulled downward and forward.

Fractures of the lower Jaw.

Although the lower jaw-bone is moveable, conſequently, capable of yielding to ſuch force as is likely to injure it, and notwithſtanding it is ſufficiently compact to make conſiderable reſiſtance, yet it is a bone which is frequently broken. The fracture may be ſituated either in its body or its branches, and be diſplaced or not. It is principally when the ſolution of continuity happens near the poſterior angle, that neither of the broken ſurfaces is thrown out of its due poſition; for in this caſe, the pterygoid, temporal, and maſſeter muſcles keep up the back part of the bone in ſuch a manner, that the ſterno-hyoidei and digaſtrici are prevented from drawing downward the anterior middle portion. A fracture of the lower jaw may be aſcertained by putting a finger into the mouth, upon the front teeth of the ſide on which the accident is ſuſpected, and by preſſing upon them at the ſame time that the fingers of the other hand are applied along the baſe of the jaw towards the angle of the ſame. When preſſure is now alternately made with each hand, the ſurfaces of the fracture will move, and often occaſion a diſtinct crepitus. The diagnoſis is much more plain when the fracture is diſplaced, for if the body of the bone ſeparates from the ramus, and falls downward, the mouth is found wide open, and drawn to one ſide in ſuch a way, that the commiſſure of the lips is conſiderably inclined downward, while the back teeth remain much higher than the front ones. If the ends of the fracture ride over each other, the mouth will appear wider on the ſide where ſuch circumſtance has occurred, and will project more forward. The teeth, alſo, inſtead of being arranged in the ſame line, will be, ſome diſplaced inward, others outward.

The generality of fractures of the jaw are attended with a conſiderable degree of ſwelling and ecchymoſis. In conſequence of the contuſion and laceration which the ſoft parts ſuſtain, very bad ſymptoms ſometimes ariſe.

In certain inſtances, either paralyſis, or a convulſive affection of the cheek of the ſame ſide is induced, by the injury done to the nerve which runs in the canalis mentalis, and has numerous communications with the portio dura of the ſeventh pair. According to writers, the hearing may be more or leſs impaired; a kind of tinnitus aurium occaſioned; ophthalmy excited; a profuſe diſcharge of ſaliva from the mouth brought on; and convulſive motions of the lips produced.

The fracture is ſometimes diſplaced, ſometimes not. In the latter caſe, it is only neceſſary to keep the injured bone well ſupported againſt the os maxillare ſuperius, by applying a compreſs on the ſide, on which the accident has occurred, and retaining ſuch compreſs in its ſituation by means of Galen's bandage, made either with four or ſix tails, and applied with its middle to the chin, while the extremities of its tails are to be pinned to the patient's night-cap.

This bandage, which is one of the beſt uſed in ſurgery, and celebrated for its antiquity, is deſcribed in another part of this work. See BANDAGE.

When the fracture is diſplaced, the plan to be followed is not quite ſo ſimple. If the anterior portion of the bone be ſituated lower down than the poſterior, the index finger muſt be put againſt the root of the coronoid proceſs, which part is to be gently puſhed backward, while the index and middle-fingers of the other hand are applied to the front teeth, and the thumb under the chin. The latter part is to be raiſed at the ſame time that the back portion of the

bone is puſhed back, ſo that the two pieces are replaced together.

In caſes in which one of the two portions is forced over the other, the fingers are to be placed, as above directed, and one piece of the bone is to be puſhed backward, the other forward, until the ſurfaces of the fracture are evenly in contact. This event may be aſcertained by the touch, by the diſappearance of deformity, and by the regularity in the arrangement of the teeth.

It very frequently happens, that a tooth is ſituated exactly in the courſe of the fracture. In this circumſtance, the generality of ſurgical writers direct us to regard the looſened tooth in the light of an extraneous ſubſtance, likely to be productive of harm, and conſequently requiring removal.

It alſo often occurs, that one or more teeth, ſituated in the vicinity of the fracture, are driven out of their ſockets. In this caſe, we are to replace the teeth without delay, and fix them in their proper places by tying them to the neighbouring ones. Celſus recommends this method, in the following terms, "ſi hi labant (dentes), ulteriores inter ſe ſetâ deligandi ſunt." Hippocrates adviſes the uſe of a piece of golden wire for the purpoſe.

Having ſet the fracture as evenly as circumſtances will allow, the next object is to apply the apparatus, by which the broken bone is to be kept from becoming diſplaced again. Cuſtom ſanctions the application of a piece of ſoap-plaſter to the integuments covering the fracture, though we ſhould have ſome difficulty to offer any good reaſon for the practice, except neatneſs of appearance; for, with regard to efficacy, there can be none.

Several oblong compreſſes are next to be prepared, in one of which a piece of paſteboard is to be put. Theſe may be wet with ſome diſcutient lotion, ſuch as that made of the aqua lithargyri acetati, or the one compoſed of vinegar, ſal-ammoniac, and ſpirit of wine. After the compreſſes have been applied, in ſuch manner as ſeems beſt calculated for keeping the fracture from becoming diſplaced, they are to be retained in their place with Galen's bandage, made either with four, or ſix tails.

The bandage alluded to is an exceedingly ancient one, being mentioned by Celſus, in treating of the fractured jaw. "Mollis habena (ſays he) media in longitudinem inciſa, ut utrinque mentum complectatur, et inde capita ejus ſupra caput adducta ibi deligentur."

During the whole of the treatment, the patient muſt refrain from making any attempt to move his jaw, and he ought to be fed with a ſpoon, and only have ſuch nouriſhment as does not ſtand in need of maſtication. When the fracture is complicated with a wound, the dreſſings ſhould be changed with the utmoſt care, and as ſeldom as circumſtances will permit. While the apparatus is off, an aſſiſtant muſt attentively ſupport the fractured bone, until the bandage is put on again.

Hippocrates conſidered it highly neceſſary, in the courſe of the caſe, to feel the inſide of the mouth tolerably often, in order to aſcertain the ſtate of the fracture, and rectify it when diſplaced.

Fractures of the jaw are generally united in about three weeks; at the end of which time, the patient may commonly be allowed to converſe, and even to leave off the bandage.

In an inſtance, in which the lower jaw was fractured by a piſtol being diſcharged in the mouth, Deſault paſſed a hollow bougie down the pharynx from the left noſtril. The inſtrument was faſtened in this ſituation with a ligature, the ends of which were pinned to the patient's night-cap. Thus food and medicines were injected into the ſtomach, without any diſturbance or motion of the jaw. The plan is certainly deſerving of imitation in every bad caſe.

Fractures of the jaw are very apt to be followed by troubleſome abſceſſes, and tedious exfoliations.

Fractures of the Zygoma.

The zygoma, which extends from the outſide of the temporal bone to the os malæ, ſeems, from its ſituation, more expoſed to fractures than all the other bones of the face. However, as far as our experience goes, it is not very often broken, and, beyond a doubt, it is much leſs frequently injured in this way, than either the lower jaw, or the frontal bone.

Two examples of the zygoma being fractured are related by Duverney in his "Traité ſur les Maladies des Os." In one of theſe caſes the fragments were depreſſed againſt the temporal muſcle; in the other, one portion projected outward. Theſe differences muſt have ariſen from the particular way in which the blow had acted in each inſtance. The patient was incapable of depreſſing the lower jaw, without conſiderable ſuffering; the pain in the ſituation of the fracture was very great; the temporal muſcle was exceedingly tenſe; and the face was ſomewhat convulſed, a circumſtance which the author imputed to the preſſure made on the branches of the portio dura of the ſeventh pair of nerves. In the patient to whom we have firſt alluded, there was felt, in the place which had been ſtruck, a kind of hollow, which was occaſioned by the depreſſion of the fragments of bone. The hollow became ſtill more evident, when the index finger was introduced into the mouth, conſiderably above the grinding teeth of the upper jaw, and then puſhed from within outward. Duverney, finding it impracticable to elevate the pieces of bone with his finger, introduced a flat bit of wood about as large as a finger over the grinding teeth, as far back as he could, and made the patient firmly ſhut the jaw. The preſſure made by this ſort of wedge, between the coronoid proceſs and the zygoma, made the latter gradually reſume its natural poſition, care being taken to uſe a thicker piece of wood, in proportion as the broken part became more and more replaced.

In the ſecond caſe, the projecting portion of the zygoma was eaſily reſtored to its proper place, by preſſure. The applications and bandage were ſimply retentive.

Fractures of the Vertebræ.

Blows, falls, the paſſage of heavy carriages over the trunk, and particularly gun-ſhot wounds, are cauſes capable of producing fractures of the vertebræ. Theſe bones, however, are ſo thick, ſhort, and ſtrong, and ſo ſurrounded with maſſes of muſcle, that, with the exception of the projecting ſpinous proceſſes, they are not frequently broken, and indeed can only be thus injured by great violence, directed in a particular manner.

Fractures, both of the ſpinous proceſſes, and of the corpora vertebrarum, are generally alarming caſes, on account of the afflicting ſymptoms which commonly enſue. The danger does not abſolutely originate from the miſchief done to the bone; but from the concuſſion of the ſpinal marrow, occaſioned by the external violence, or from the compreſſion or laceration of the ſame part, ariſing from ſome of the fragments of bone being driven againſt it. The injury, indeed, which the parts within the ſpinal canal often ſuſtain, is ſo great, that, if the patient lives a certain time, they often inflame, and a large quantity of matter is formed around the continuation of the dura mater, which covers the medulla ſpinalis.

Cocchi, an Italian practitioner, has noticed all the bad ſymptoms with particular preciſion. In ſpeaking of the bony fragments, he obſerves, "officulis comminutis, medullam per ea deſcendentem comprimi, pungi atque inflammari neceſſe eſt, et ſubjectas corporis partes univerſas reſolvi ac veſicæ et recti inteſtini vim conſtringentem amitti, adeo ut urina et excrementa vel ſupprimantur, vel ſine voluntate prorumpant. Quâ certiſſimâ atque evidentiſſimâ notâ, nos ſæpe conjecimus vertebræ alicujus proceſſum ſpinoſum introrſum confractum fuiſſe; et quum plerumque vel cita vel tarda inſecuta ſit, inciſis corporibus, id mali ſolum fuiſſe vidimus, etſi nullo modo vertebræ exciderint. Antiqui id parum perſpexiſſe videntur, à quibus noxæ et pericula vertebris luxatis tribuuntur, quæ revera fractarum ſunt. Hoc infortunium longe frequentius quoque quam illud accidere comperimus, ſecùs ac illi putarunt." Notwithſtanding the ſentiment of the foregoing author, that ſuch ſymptoms are particularly apt to proceed from a fracture of ſome of the ſpinous proceſſes, it is certain, that the more common cauſe is a fracture of the corpora vertebrarum, the damage done to which is often irremediable.

Practitioners, however, ought to be appriſed, that a ſimilar train of evils may depend altogether on a concuſſion of the ſpinal marrow, without any fracture whatever. This fact, in caſes in which the bodies of the vertebræ are ſuſpected to be broken, always throws an immoveable degree of doubt and obſcurity over the real ſtate of circumſtances. A fracture of the ſpinous proceſſes may often be diſtinctly felt; but that of the other parts of the vertebræ in general only admits of ſuſpicions, which can never be confirmed, except where the fatal termination of the caſe gives the ſurgeon an opportunity of opening the body.

It was a circumſtance obſerved by Albucaſis, that fractures of the upper vertebræ are, for the moſt part, attended with a paralyſis of the upper extremities, while fractures of the lumbar vertebræ were generally productive of a paralytic affection of the lower ones. Avicenna remarks, that ſuch injuries of the corpora vertebrarum always occaſion death, which ſeldom enſues from a mere fracture of one or more of the ſpinous proceſſes. The latter kind of accident, indeed, has been known to occur, and the fragments of bone to be at the ſame time diſplaced, without the acceſſion of any alarming ſymptoms. The caſe is always to be regarded as much leſs dangerous than one in which any other part of the vertebra is broken.

Notwithſtanding the opinion delivered by Avicenna, it is certain that a fracture of the body of a vertebra is not neceſſarily fatal in every inſtance, eſpecially when the accident has ariſen from a gun-ſhot wound. Several examples, confirming the truth of this remark, are to be met with in ſurgical books. In the majority of examples, however, the patients linger, and die of a ſlow ſort of fever.

When the bodies of any of the vertebræ are fractured, the practitioner only has it in his power to render himſelf uſeful, by paying attention to general indications. Circumſtances, however, are different, when the ſpinous proceſſes are broken. In theſe inſtances an endeavour is to be made to put the detached fragments of bone in their right ſituation; an object which may ſometimes be accompliſhed, when the parts make a conſiderable projection.

Writers on ſurgery alſo ſpeak of uſing an elevator for raiſing depreſſed pieces of fractured vertebræ, when the accident is complicated with a wound; of this practice we can ſay nothing ourſelves, ſcarcely being able to conceive that any opportunity for it can occur, or that the thing is very practicable.

In caſes of fractured vertebræ a roller may be applied round the body, and kept from ſlipping down by a ſcapulary; but it is plain, that ſuch an apparatus is more for the ſake of appearances, than of any real efficacy. When the ſpinous proceſſes are broken, the compreſs ought to be put under the bandage along each ſide of the detached fragments.

All injuries of the ſpine are apt to produce paralyſis of the lower extremities, and of the bladder and rectum. Hence the patient is frequently incapable of voiding his urine, and the practitioner is obliged to have recourſe to the catheter. In many caſes the urine comes away without the patient's knowledge, and the fæces are alſo involuntarily diſcharged. See INCONTINENCE *of Urine*, and RETENTION *of Urine*.

Fractures of the Sternum.

When the ſternum is broken, it is generally in conſequence of a very violent fall againſt ſome hard projecting body. The accident being produced in this manner, the fragments of bone ſeldom continue exactly in their natural poſition, but are almoſt always more or leſs diſplaced, and, by making preſſure on the neighbouring parts, give riſe to ſymptoms of an urgent nature. Sometimes the violence of the blow ruptures one of the internal mammary arteries, ſo that an extravaſation takes place, and brings on a train of alarming complaints. Such an effuſion of blood, however, is more frequently attendant on gun-ſhot injuries of the ſternum, than common fractures. The patient does not in the firſt inſtance experience conſiderable ſuffering, becauſe the extravaſation occurs ſlowly, and the layers of the mediaſtinum make a good deal of reſiſtance to the diffuſion of the blood. At length, however, the quantity effuſed becomes very great, and an exceſſive difficulty of breathing, and a ſenſe of weight in the region of the ſternum, are the conſequences. It is ſaid that on examining the integuments covering the bone, a kind of incipient œdema may be felt, which ſhould draw the ſerious attention of the practitioner to the effects which are likely to enſue.

When the mammary veſſels are uninjured, and the above ſort of ſymptoms ariſe, they are much later in making their appearance. They are alſo dependant, not on an effuſion of blood, but on the formation of abſceſſes in the vicinity of the fracture, and beneath the bone. Such purulent collections have alſo been compared by ſurgical authors, with the ſuppurations which ſo frequently happen under the cranium in conſequence of injuries of the head, from external violence. The writings of Juncker, Duverney, and J. L. Petit, ſhew the truth of this obſervation. Verduc, who refers the bad ſymptoms to the pieces of bone being driven inward, and recommends the fragments to be elevated, deſcribes the complaints as even more dangerous, and more ſpeedily fatal than thoſe which are produced by blood or matter under the cranium.

When the fracture of the ſternum is a ſimple one, unattended with any particular complaints, has been occaſioned by a fall or blow, and the fragments are not at all diſplaced, the treatment is reduced to great ſimplicity. The patient is to be kept on a low regimen, at perfect reſt, and ſhould be bled and purged according to the exigency of the caſe. The topical part of the treatment conſiſts in applying ſome ſoap-plaſter to the ſituation of the injury, and a roller round the body, with a ſcapulary.

When any portion of the fractured ſternum is beaten inward, ſo as to preſs upon and dangerouſly irritate any of the ſubjacent parts, the depreſſed piece ſhould be raiſed without loſs of time. For this purpoſe, it will generally be neceſſary to make a diviſion of the integuments with a

ſcalpel

ſcalpel, and then to employ the inſtrument called an elevator, much in the ſame way as it is uſed on the ſkull. See ELEVATOR and TREPANNING.

In gun-ſhot wounds of the thorax, the ſternum may be ſhattered into many pieces. In ſuch a caſe, it would be the duty of the practitioner to remove, with a pair of forceps, all the detached fragments, which, if left in the wound, would not unite to the reſt of the bone; but only act as extraneous bodies.

Where an extravaſation of blood, or a collection of purulent matter, under a fractured ſternum, are known to exiſt, and to be the cauſe of urgent and perilous ſymptoms, the ſurgeon would be called upon to make a perforation in the bone with a ſmall trephine. However, before having recourſe to this proceeding, he ought to be ſure that the bad ſymptoms do depend on the preſence of a fluid in the anterior mediaſtinum, and are not altogether the effect of inflammation conſequent to the violence.

We ſhall conclude theſe remarks on fractures of the ſternum with ſtating, that as the chief danger of ſuch caſes is in proportion to the irritation and inflammation which are excited in the thoracic viſcera, the principal objects in the treatment are, to prevent the broken pieces of bone from hurting the pleura, pericardium, and lungs, by projecting inward, and to avert inflammation in the cheſt, as much as poſſible, by repeated veneſections, low diet, quietude, aperient medicines, &c.

Fractures of the Ribs.

The ribs are broken almoſt as frequently as any bones of the human body. The labourer who falls from a ſcaffold, the poor fellow who is run over by a carriage, the man of pleaſure who is thrown from his horſe, the ſailor who tumbles from aloft, and all deſcriptions of perſons ſubject to falls in running up and down ſtairs and ladders, are often under the ſurgeon's care for fractured ribs. Only one of theſe bones may be broken, but in many caſes the accident befals ſeveral at the ſame time. The part of the ribs where fractures are moſt commonly ſituated is their greateſt convexity, which muſt obviouſly be the moſt expoſed to the effects of external violence.

The falſe ribs are not ſo apt to be fractured as thoſe which have the epithet true given to them. The reaſon of this circumſtance is owing to the moveable nature of the former, a quality which enables them to elude the conſequences of external force. The guarded ſituation of the firſt true rib beneath the clavicle is alſo a cauſe why it is very ſeldom broken.

The diagnoſis of fractures of the ribs is ſometimes ſufficiently plain, but in numerous inſtances the moſt diſcerning ſurgeon can obtain no certainty. When the patient is thin, when ſeveral ribs are fractured, and particularly when the ends of the fracture are diſplaced inward or outward, the practitioner is always able to aſcertain the nature of the accident, beyond the ſhadow of a doubt. Under theſe circumſtances, a crepitus may alſo be felt on making the patient cough, ſo as to ſhake the injured bones, and at the ſame time placing one's hand upon the hurt ſide of the thorax.

However, more obſcurity often prevails, when the patient is fat, when only a ſingle rib is broken, and when the ends of the fracture are undiſplaced. A pricking ſenſation in the ſide, attendant on the motion of the ribs in reſpiration, is frequently a juſt ground of ſuſpicion, that one of theſe bones is fractured, eſpecially when the nature of the fall, or blow, makes the accident not improbable. In all caſes of doubt, the prudent ſurgeon makes it an invariable maxim to act in the ſame way as he would do were he certain that the ribs are broken. This line of conduct is particularly commendable; becauſe it can do no harm, ſuppoſing no fracture to exiſt, and when ſuch an injury has really happened, the relief and the prevention of dangerous conſequences, reſulting from the adoption of the proper treatment, are of the greateſt importance.

The practice, in caſes of fractured ribs, conſiſts in diminiſhing the motion of theſe bones as much as poſſible, taking meaſures for the hindrance and diminution of inflammation of the pleura and lungs; and, in particular, in appeaſing any cough under which the patient may happen to be ſuffering.

The firſt of theſe indications is fulfilled by means of a roller applied round the thorax as tightly as the patient's feelings will permit. Inſtead of a roller, the generality of ſurgeons rightly prefer employing a ſtrong piece of linen, large enough to ſurround the cheſt, and laced with due tightneſs in front of the body. Such an apparatus is not ſo apt to become ſlack as a roller, and it has this advantage, that the patient himſelf, in the abſence of the ſurgeon, can eaſily increaſe or diminiſh the tightneſs of the cloth, as circumſtances may require. Before putting on any kind of bandage, however, the ſurgeon ſhould examine the ſituation of the fracture, and put the ends of the bone, or bones, as nearly as poſſible into a right poſition. This object is to be effected by making ſkilful preſſure with the fingers on the injured ribs. It is uſual alſo to apply a piece of the ſoap-plaſter to the integuments in the vicinity of the fracture. Together with ſuch application, one or two compreſſes may be uſed, if the practitioner is of opinion that they will be of any ſervice in keeping the ends of the bone, or bones, ſteady, and in their proper poſition.

Whether the bandage conſiſt of a common roller, or a broad piece of cloth laced in front, a ſcapulary muſt be employed for the purpoſe of preventing the apparatus from ſlipping downward.

One of the principal dangers ariſing from fractures of the ribs, is inflammation of the pleura, or membrane which lines the cheſt. Hence the ſecond indication which we above ſpecified, and which is fulfilled by ſtrict attention to the antiphlogiſtic ſyſtem of treatment. Indeed, all experienced ſurgeons, on being firſt called to a patient having a fractured rib, or ſuſpected of having ſuch, make it a rule to direct immediate veneſection, and to take away about ſixteen or eighteen ounces of blood. The evacuation is to be repeated or not, according to circumſtances. It is only in very debilitated, aged ſubjects, that it is right to diſpenſe with bleeding.

Sometimes the point of a fractured rib, by being beaten inward, lacerates ſome of the air-cells of the lungs. In conſequence of this accident, a portion of the air contained in theſe organs inſinuates itſelf between the pleura pulmonalis and pleura coſtalis every time that the cavity of the cheſt is enlarged in inſpiration, and thence partly eſcapes into the common cellular membrane of the body through the breach in the pleura coſtalis, on every diminution of the thorax in expiration. The ſwelling of the parts which are thus inflated with air, is termed emphyſema, and frequently takes place in a degree almoſt incredible, the cellular ſubſtance becoming ſo diſtended as to be in many parts of the body ſeveral inches thick. The principal danger, however, is not from this diffuſion of air; but from its confinement in the cheſt, where it often accumulates more quickly, than it can eſcape through the laceration in the pleura, and conſequently produces ſuch a degree of preſſure on the mediaſtinum, diaphragm, and oppoſite lung, that a fatal

fatal interruption of reſpiration is occaſioned. We need not ſay more at preſent concerning this affection, as it is treated of elſewhere. See EMPHYSEMA.

Another occaſional attendant on bad caſes of fractured ribs, is an extravaſation of blood in the cavity of the cheſt. Such an effuſion and an emphyſema we have, in certain inſtances, found exiſting together. The reader will find ſome obſervations on extravaſation in the cheſt, in the articles EXTRAVASATION and WOUNDS.

Fractures of the Os Ilium, Os Iſchium, and Os Pubis.

The ſtructure of the os ilium and os iſchium is ſuch, and the muſcles upon them are ſo numerous and bulky, that fractures of theſe bones hardly admit of being felt, except when ſituated about the upper part of the ilium, or the tuberoſity of the iſchium. Neither theſe bones, nor the os pubis, however, are very frequently broken, and when the accident does happen, it is almoſt always in conſequence of gun-ſhot injuries, or the paſſage of heavy carriage-wheels over the pelvis. Boyer has recorded an inſtance in which the anterior ſuperior ſpinous proceſs was fractured by the kick of a horſe. It is eaſy to conceive that the ſame deſcription of violence might alſo break either the os pubis, or the criſta of the ilium. As great violence is generally requiſite to produce the breach of continuity, the integuments and muſcles are commonly ſeverely injured at the ſame time, as well as the viſcera of the pelvis. Indeed, the danger of theſe accidents may be eſtimated by the degree of miſchief done to the internal parts, for it is from this cauſe that a fatal inflammation of the bladder, inteſtines, and peritonæum, and a train of afflictions depending on a paralytic affection of the urinary organs frequently originate.

When the os ilium is fractured all acroſs, the accident may in ſome inſtances be detected by making preſſure on the criſta of this bone, by which means a crepitus may ſometimes be rendered perceptible. The fragments of the fracture are very ſeldom diſplaced, being retained in their proper ſituation by the glutæi and iliacus internus muſcles.

In order to diſcover fractures of the os ilium, the ſurgeon ſhould make the patient lie on that ſide of the body which is free from injury, with the thorax and abdomen inclined forward, and the thighs bent.

When a ſuſpicion is entertained that the os pubis is fractured, the examination ſhould be made while the patient lies upon his back with his cheſt inclined forward, and his thighs in a ſtate of flexion.

Fractures of the os iſchium may be diſcovered by examining juſt under the lower edge of the buttock, by the ſide of the anus.

The ſwelling which occurs very often renders all information, derived from handling the parts, exceedingly obſcure and doubtful. In this circumſtance, the practitioner can only conjecture that a fracture of ſome part of the pelvis has happened from a conſideration of the ſymptoms. Theſe are generally of the following deſcription; a difficulty of walking, in conſequence of a blow, or fall on the pelvis, or of the paſſage of a carriage over it, a retention of the urine and fæces, followed by an incontinence of the ſame, oppreſſive pains, a paralytic affection of the thighs and legs, œdema of theſe parts, and even ſloughing. Very often, in conſequence of the violence done to the viſcera, hiccough and vomiting are excited, and extravaſations of blood, and collections of matter are produced.

The majority of ſuch patients as we have known die from fractures of the os ilium, os iſchium, and os pubis, have fallen victims to extenſive inflammations in the pelvis and abdomen.

We have already remarked, that the fractures themſelves are ſeldom diſplaced, ſo that what relates to their treatment is exceedingly ſimple, merely conſiſting in applying a roller round the pelvis, and putting a piece of ſoap-plaſter on the ſituation of the broken part. The grand indication is to obviate the conſequences of inflammation of the parts within of the pelvis, and of the peritonæum and abdominal viſcera, by copious and repeated veneſections, and the application of leeches and bliſters to the hypogaſtric region, on the very firſt occurrence of pain or tenſion.

All complaints, in regard to the evacuation of the urine and fæces, are alſo to be carefully attended to. The ſurgeon muſt never neglect to employ the catheter as often as circumſtances require, and he ſhould endeavour to deviſe proper means for preſerving a due degree of cleanlineſs, which is ſo eſſential to the recovery of perſons likely to undergo a long confinement.

In many caſes the violence inflicted is ſo great, that the patient cannot move in the leaſt for the purpoſe of obeying the calls of nature, without being put to the moſt excruciating and intolerable agony. Boyer ſucceſsfully contrived, by means of a piece of girth web laid under the pelvis of one of his patients, and faſtened to a pulley fixed at the top of the bed, to enable the poor ſufferer to raiſe himſelf ſufficiently from the ſurface of the bed to let a pan be put under him for the reception of the fæces. However, a bed made on the principles of the one lately recommended to the public by ſir James Earle, would be the moſt advantageous.

In certain examples abſceſſes cannot be prevented from forming in the pelvis, notwithſtanding the moſt judicious treatment. Suppurations of this kind are particularly apt to ariſe when any detached ſplinters of bone are driven inward.

It is poſſible for the bladder to be wounded by a ſharp ſpicula of the fracture, and an extravaſation of urine to be the conſequence. Default met with a caſe of this deſcription, where the piece of bone was taken out of a wound which was made to let out the effuſed urine. Were ſuch a caſe to preſent itſelf, the practitioner ſhould keep a gum catheter conſtantly introduced, in order to prevent any quantity of urine from collecting, and afterwards becoming diffuſed.

Fractures of the Os Sacrum.

The os ſacrum cannot be broken without the operation of conſiderable force. Hence the accident is not frequent, and, when it does happen, is generally occaſioned by the fall of a very heavy body immediately againſt the bone, the paſſage of a cart or waggon over its convex ſide, or by high falls on the part. The upper portion of a broken ſacrum obviouſly cannot be diſplaced, by reaſon of the firm manner in which it is connected with the lower lumbar vertebra. The lower piece is alſo ſeldom diſplaced, becauſe there are no muſcles which tend to produce ſuch an effect. The violence itſelf, however, may ſometimes drive the inferior fragment inward, an event which is more likely to occur when the fracture is ſituated low down towards the os coccygis.

As in the caſes which form the ſubject of the foregoing ſection, the chief part of the peril depends upon the injury which the pelvis and abdominal viſcera have ſuſtained, and the inflammation which they may undergo, ſo, in the preſent inſtances, the danger principally originates from the ſame cauſe, and the miſchief done to the ſeveral nerves.

From the ſhort ſtatement already made, it muſt be evident that the indications in the treatment of a fractured ſa-

crum

orum are very much like thoſe which preſent themſelves in the foregoing ſpecies of fractures. The fractured ſurfaces being ſeldom ſeparated and diſplaced, the injury of the bone commonly demands a very ſimple plan, which conſiſts in applying a piece of the emplaſtrum ſaponis and a T bandage. If a caſe ſhould occur in which the lower fragment is diſplaced, the reduction is to be accompliſhed in the way which will be explained in treating of fractures of the os coccygis.

The moſt alarming ſymptoms, and ſuch as require the utmoſt ſurgical ſkill, are the inflammation which is apt to affect the viſcera, the retention, or incontinence of urine, the involuntary diſcharge of the fæces, and the paralyſis of the lower extremities, complaints which too frequently attend the accident, and bring on a fatal termination.

Upon this ſubject we need not here enlarge, as we have already delineated the proper plan of treatment in ſpeaking of fractures of the other bones of the pelvis, and further information will be found in future articles. See INCONTINENCE *of Urine*, and RETENTION *of Urine*, *&c.*

Fractures of the Os Coccygis.

The os ſacrum, although a bone of conſiderable ſtrength, is more frequently broken than the os coccygis, which eludes the effect of external violence by its great degree of moveableneſs. Force operating, however, in a particular manner, may occaſion a fracture, and one ſymptom of the accident is ſaid to be an acute pain in the ſituation of the injured bone, when the patient walks, which exertion puts into action the fibres of the glutæi muſcles ariſing from the part.

A fracture of the os coccygis may alſo be diſplaced by the lower fragment being driven inward. When this is the caſe, the practitioner ſhould endeavour to replace the piece of bone, by means of his fore-finger introduced into the rectum, and the ſkilful aſſiſtance of the fingers of his other hand externally.

With regard to the treatment adapted for keeping the fracture in a ſteady and undiſplaced condition, the practitioner can do little more than apply a piece of the emplaſtrum ſaponis and a T bandage, the patient being enjoined to avoid walking and making any preſſure on the part.

Fractures of the Clavicle.

The ſituation, the ſlenderneſs, and the curved ſhape of the clavicle; the manner in which the bone is only ſupported at each end; the great efforts which it has to ſuſtain when, in falling, the hands are brought forward; and ſeveral other anatomical and incidental conſiderations ſufficiently obvious, afford a full explanation of the reaſon why fractures of the clavicle happen exceedingly often, and are much more common than its diſlocations. The middle of the bone is more frequently broken than its other parts, and the fracture is almoſt always diſplaced, on account of the weight of the arm and the action of the pectoral muſcle, the humeral portion of the bone falling under that which remains connected with the ſternum. Encyclopédie Méthodique, Partie Chirurgicale, art. Clavicule.

A fracture of the clavicle is a caſe in which the diagnoſis is remarkably eaſy; the accident, indeed, being obvious at firſt view, eſpecially when the fragments are diſplaced, when there is no ſwelling, and when the patient is not exceedingly fat. The ſhoulder becomes depreſſed, approximated to the ſternum, and ſo inclined towards the thorax, that there is no ſpace betwixt them. It is only with difficulty that the arm can be raiſed, brought forward, or put to the ſide. When the fracture is ſimple, and its ends not conſiderably ſeparated, the pain is ſometimes moderate, or even trifling; but, upon the gentleſt attempt being made to move the arm, the patient ſuffers great agony, which ceaſes immediately the fracture is replaced. When the fractured bone is not in its due ſituation, the humeral portion drawn down by the weight of the ſcapula, by that of the arm, and by the action of the deltoid muſcle, becomes concealed under the ſternal portion. The diſplaced condition of the bone is increaſed whenever the muſcles act with violence, and the pain is aggravated by carrying forward the arm, or preſſing it forcibly to the ſide.

It is not common for a fracture to occur at the ſcapulary end of the clavicle; but there is no doubt that a direct force, falling on the ſhoulder, may break any part of the bone. When the accident is thus produced, the ſoft parts may alſo ſuffer more or leſs contuſion and laceration. The bone may be broken in more places than one, and the caſe receive the appellation of a comminuted fracture.

When the violence acts upon the extremities of the clavicle, as happens in falls on the outſide of the ſhoulder and on the hands, while the arms are extended, the clavicle may be very much bent, and ſo obliquely broken, that the ends of the bone will protrude through the ſkin, and occaſion what is termed a compound fracture.

Exceſſive violence applied to the ſhoulder may injure the cervical nerves, and has been known to bring on a paralyſis of the arm, an affliction with which fractures of the clavicle may of courſe be ſometimes complicated.

Although the records of ſurgery fully demonſtrate that fractures of the clavicle have been, from the earlieſt periods, among the moſt common accidents to which mankind have always been ſubject, yet it is well known that the treatment of no other kind of fracture remained ſo long as that of the collar-bone in a ſtate of imperfection and error. Falſe notions and abſurd practice deſcended regularly from one generation of ſurgeons to another, from the days of Hippocrates to thoſe of Pott and Deſault.

The following obſervations, taken from Deſault's Pariſian Chirurgical Journal, tranſlated by Mr. Goſling, afford a good explanation of the opinions which have prevailed reſpecting the treatment of fractures of the clavicle.

"The attention of the Greek phyſicians was directed to the projection generally formed by the ſternal fragment, which they conceived ſhould always be depreſſed to the level of the humeral portion; and they endeavoured to accompliſh this object by mechanical means; ſuch as the application of lead, or thick compreſſes, retained on the clavicle by means of bandages. Such was the method employed, till the inſufficiency and bad tendency of this practice were pointed out by Hippocrates, who, being more accurate and attentive in his obſervations than his predeceſſors, remarked that the projecting end of the ſternal portion was in fact not more elevated, but that this appearance aroſe from the humeral portion being depreſſed, in conſequence of being drawn down with the ſhoulder, and that conſequently our endeavours ſhould be directed to raiſe this portion on a level with the other. Such are the principles on which his doctrines and practice were founded; he recommends the arm to be brought to the ſide, and the ſhoulder to be elevated, ſo as to form an acute angle, and to be maintained in that ſituation by a proper bandage. This plan, according to our author, will tend to bring the ends of the bone in a ſtate of appoſition, and procure their reunion, at leaſt it will effect this when the humeral portion is depreſſed below the ſternal, which is generally the caſe. But this method will not always completely ſucceed; for inſtance, when the bones ride over each other, or when the

ſcapular

ſcapular portion is forced backwards. In theſe caſes, Hippocrates recommends the patient to be laid on a hard body, (a plank, for inſtance,) and his ſhoulders to be drawn backwards with ſome degree of force, and maintained in this ſituation by a ſort of ſpica bandage. If the ſcapular fragment ſhould project forward, he recommends the elbow to be brought forward on the breaſt, and the palm of the hand to be applied againſt the oppoſite ſhoulder. And, with reſpect to the caſe, which very rarely occurs, of the ſcapular portion projecting above the ſternal, he ſays nothing, as the weight of the ſhoulder is alone ſufficient to bring it to its former ſituation.

"What Paulus Æginetus ſays on fractures of the clavicle ſeems to be a commentary on the text of Hippocrates; he makes his extenſion by carrying the arm upwards and outwards. In certain caſes, he places a compreſs between the ſhoulders, whilſt an aſſiſtant draws them backwards, and then applies a ſpica bandage; he alſo mentions, that the arm ſhould not be ſupported, but left hanging to the ſide, when the humeral portion is more elevated than the ſternal; in a word, his ideas and practice are preciſely the ſame; the only circumſtance in which he varies, is recommending a ball to be placed in the axilla, to make a more forcible extenſion, when the means recommended by Hippocrates are inadequate to the reduction.

"Albucaſis, the author, who revived ſurgery among the Arabians, borrowed of Paulus Æginetus the idea of placing a ball in the axilla, and the uſe of the figure-of-8 bandage: he kept the ſhoulder conſtantly elevated, and ſupported the arm during the day in a ſling, which he fixed, in the day, to the neck of the patient, and ſupported, at night, by placing a pillow under the axilla.

"Lanfranc and Gui de Chaubac have only tranſcribed what has been ſaid by the above-mentioned authors: the laſt, inſtead of laying the patient on a thick pillow, attempts the reduction by applying the knee between the ſhoulders of the patient (agreeable to moſt modern practitioners, who have imitated this practice); and, if the depreſſed portion was not by this means ſufficiently elevated, he recommended the application of an agglutinative plaſter to produce this effect, a doctrine ſo abſurd, that we are aſtoniſhed to find it mentioned by ſome modern authors.

"Pecceti has gone farther than preceding writers, whoſe works he has attentively conſidered, and from whom he has frequently tranſcribed; for, he recommends the ball to be left in the axilla during the whole treatment, but ſtill uſes the figure-of-8 bandage.

"Subſequent writers have only commented on thoſe authors we have recited; but, as the greateſt part were not practitioners, they have omitted the explanation of one part of their doctrine, the moſt eſſential of all.

"The ball, which, with Paulus Æginetus, Avicennus, and Albucaſis, was the principal means of reduction, has been viewed only by the moderns as merely a means to fill up the axilla, to prevent the parts being excoriated from the application of the bandage: but this is not the only error into which they have fallen; the fracture of the clavicle was invariably followed with more or leſs deformity, a remark generally made. Moſt ſurgeons, miſled by a falſe theory reſpecting the union of fractures, conceived it was impoſſible to ſurround the clavicle by a bandage that would prevent the irregular ſhooting of the callus. Some, however, obſerved that the bandage of the ancients, then in uſe, did not prevent the motion of the fractured portions; but the means that they ſubſtituted and adopted on the ſame principles were not found to anſwer the intention.

"The iron croſs of Heiſter and of the author of "La Chirurgie complette," the compreſs by which Mr. Petit kept the ſhoulders backwards, and other contrivances, are only different modifications of the figure-of-8 bandage; the inconveniences and inſufficiency of which are demonſtrated by every modern author; and, indeed, it is unneceſſary to reaſon on the ſubject, as we find, from experience, it is abſolutely inadequate to produce the effect we wiſh; and, indeed, in the opinion of all ſurgeons, no bandage has been yet contrived to retain the fractured parts ſufficiently to prevent deformity and pain.

"Default, firmly perſuaded that a conſtant ſtate of extenſion was abſolutely neceſſary to keep the parts in a ſtate of immobility and procure their re-union, invented, in 1768, a bandage that completely anſwered this indication, which ſome perſons have conceived is to be found in Paulus Æginetus. This author certainly accompliſhed the reduction when it was difficult, by bringing the elbow on the breaſt, and ſeparating, at the ſame time, the ſuperior part of the arm, by means of a thick ball placed in the axilla; but, from his own account, we learn, that he did not keep up this means of extenſion during the whole treatment. He, indeed, adds, in a few lines, that after the reduction of the fracture, and applying thick compreſſes, a ball of wool ſhould be placed in the axilla, and the bandage ſhould paſs under both axillæ, on the fractured clavicle, ſcapula, &c.

"After the application of this bandage, it is evident, that placing a ball of wool in the axilla was merely to furniſh a point of ſupport to the bandage, which, without this precaution, would have paſſed only over thoſe parts where the muſcles project. What further confirms this idea is, that the author employs no method to keep the arm cloſe to the trunk; but reſts ſatisfied with ſuſpending it to the neck by means of a leather ſtrap, and ſupporting the fore-arm in a ſling, in the ſame way as after bleeding. Pecceti recommends the ball that was uſed in the reduction to be kept in the axilla; but ſtill we do not ſee his direct indication, as he employs, like his predeceſſors, the bandage of the figure of 8, and ſays nothing of the manner of retaining the ball, nor of the neceſſity of keeping the arm cloſe to the trunk."

Default uſed to ſet a broken clavicle in the following manner. The patient was deſired to ſtand, while an aſſiſtant elevated the arm ſufficiently to make it perpendicular to the axis of the body. Default next applied to the ſide of the breaſt a pad, made of old linen, as long as the humerus, in the form of a wedge, the width of which was from four to five inches; and the baſe, which was three inches thick, was placed in the axilla, and retained in that ſituation by means of a bandage five or ſix ells in length, and three fingers in breadth. One end was applied to the middle of the pad, and confined in that ſituation by two circular turns round the body, then paſſed before the breaſt above the right ſhoulder, then behind, and afterwards under; the roller was then brought horizontally before the breaſt on the pad, then obliquely upwards behind the breaſt, on the right ſhoulder, juſt forwards, and then under; then it was carried horizontally behind the breaſt on the pad, and continued in the ſame way till the whole bandage was expended.

The ſurgeon ſupported the pad in the axilla with one hand, and with the other elevated the elbow, ſo as to bring the ſcapular fragment of the clavicle in contact with the ſternal portion, preſſing the pad againſt the breaſt; making with the arm, by this method, a lever of the firſt ſpecies, by which means the arm was brought from the trunk, and the clavicle kept in a ſtate of extenſion.

An aſſiſtant was deſired to retain the arm in this ſituation with one hand, and with the other to ſupport the fore-arm,

bent

bent in a horizontal poſition; the palm of the hand applied to the anterior part of the breaſt. By this plan of treatment the bones were brought to their natural ſituation, and to ſuch an exact ſtate of appoſition, that no irregularity or deformity remained.

The arm was retained in this poſition by a bandage of ſix or ſeven ells in length, and four fingers in breadth; the end was applied before the right axilla, and brought horizontally before the breaſt, on the ſuperior part of the arm, behind the breaſt, and under the axilla: this firſt turn of the bandage was farther ſecured, by being twice paſſed in the ſame manner: the turns were then reflected over each other, and expanded on the breaſt and the reſt of the arm; and, as it approached near the elbow, the bandage was drawn tighter, and paſſed in circular turns round the fore-arm, and pinned to that part.

The corners of the pad were pinned to the upper part of the bandage, and the hand received an additional ſupport by the middle of a compreſs, the ends of which were pinned to the anterior part of the bandage; the vacuities above and below the clavicle were filled with lint; and the fractured portions covered with compreſſes, dipt in aq. veg. which were doubled, and ſeven or eight inches in length, and three wide.

Under the right axilla, the end of a bandage, ſeven or eight ells in length, and three fingers wide, was applied, and paſſed obliquely above the breaſt, on the compreſſes which covered the clavicle, behind the ſhoulder and the arm, under the elbow, (which the aſſiſtant ſtill continued to ſupport,) then obliquely upwards before the breaſt, and under the right axilla. Over the firſt turn of the bandage it was paſſed three times preciſely in the ſame way, and the remainder of the bandage, brought from behind forwards under the right axilla, was expended in circular turns, paſſed from the right to the left on the arm, and round the breaſt, to fix the firſt part of the bandage, and to carry back the arm that correſponded with the fractured clavicle: particular attention was paid to prevent the bandage getting looſe, by ſecuring it in different parts by means of pins. See Pariſian Surgical Journal, vol. i.

Deſault's bandage is ſimple, although ſome attention will be neceſſary in applying it. Its mode of acting is obvious. The cuſhion or compreſs, which acts as a ſupport to the internal ſurface of the arm, is ſhaped in ſuch a manner, that at the time the elbow is brought cloſe to the breaſt, the ſuperior part of the arm is ſeparated ſome diſtance from the body. The arm, carried outwards, drags the ſhoulder at the ſame time, and with it the ſcapular portion of the fractured clavicle, which would have been carried inwards by the pectoral muſcles, the ſeratus major anticus, and the ſubclavius, if their action had not been oppoſed by the thickneſs of the ſuperior part of the cuſhion. The circular turns of the bandage, which fix the arm againſt the breaſt, have the double advantage of keeping up the extenſion, and preventing at the ſame time the motions of the arm and ſhoulder, and, conſequently, retaining the portions of the fractured bone in a conſtant ſtate of appoſition. The elevation of the arm tends to place the humeral portion of the clavicle on a level with the ſternal; and the turns of the bandage, paſſing at one part under the elbow and fore-arm, and at another part on the fragment that is moſt elevated, which it depreſſes, and raiſes the other, bringing their ſurfaces oppoſed to each other. This bandage ſerves to confine the actions of the trapezius and ſterno-maſtoideus, which are attached to this bone. With reſpect to the ordinary time for the conſolidation of the fracture, Hippocrates fixes it from fourteen to twenty days; Albucaſis, from twenty to twenty-four or twenty-eight; and this calculation agrees nearly with the reſult of Deſault's experience. Pariſian Chirurgical Journal.

Notwithſtanding the excellency of the foregoing plan, Engliſh ſurgeons are not much in the habit of following it, perhaps on account of its being a little more complicated than the method of confining the ſhoulders back with a figure-of-eight-bandage, and ſupporting the arm in a ſling, as is their uſual mode. The obvious imperfection of the figure-of-eight bandage is, that it tends to depreſs the ſcapulary end of the clavicle, at the ſame time that it draws it backward. We need ſcarcely remark, that when ſuch bandage is uſed, the margins of the axillæ muſt be defended with tow, and that it is cuſtomary to put a piece of the emplaſtrum ſaponis on the ſkin covering the fracture.

Fractures of the Scapula.

The ſituation of the ſcapula, and the quantity of muſcle upon it, render the body of this bone not very liable to be broken; but the accident does every now and then take place. Particular parts of the ſcapula, however, are frequently fractured; as, for inſtance, the acromion, the inferior angle, the neck, and the coracoid proceſs.

When the acromion is broken, the weight of the arm, and the contraction of the deltoid muſcle, draw the detached piece downward, while the trapezius and levator ſcapulæ draw the reſt of the bone upward and backward.

When the lower angle of the ſcapula is broken, it is drawn forward by the action of the ſerratus major anticus, the reſt of the bone remaining in its natural ſituation. If the portion of the angle fractured off be conſiderable, it may alſo be pulled upward and forward by the teres major, and ſome fibres of the latiſſimus dorſi.

In fractures of the coracoid proceſs, this part is ſeparated from the reſt of the ſcapula, in conſequence of being drawn downward and forward by the action of the coraco-brachialis and ſhort head of the biceps.

Fractures of the neck of the ſcapula are followed by a falling down of the ſhoulder, occaſioned by the weight of the arm. The appearance of the limb is like that of a diſlocation; but the difference of the caſe is eaſily diſtinguiſhed by the facility with which the os brachii may be puſhed up to its proper height, the perception of a crepitus, and the falling down of the limb again, as ſoon as it is left unſupported.

It frequently happens, that after a fall, or blow on the ſhoulder or arm, when the clavicle and ſcapula cannot be diſcovered to be any where broken, a great deal of pain, and a manifeſt crepitus occur on moving the ſhoulder-joint. It is probable that, in ſome caſes of this kind, a ſmall portion of the head of the os brachii, or a little piece of the glenoid cavity of the ſcapula, may be broken off.

The ſymptoms of a fractured acromion are, pain in the ſituation of the injury, a change in the external appearance and ſhape of the ſhoulder, and a falling downward of the detached portion of the bone, which may be raiſed into its proper poſition by bringing up the elbow cloſe to the ſide.

Fractures of the inferior angle are very obvious and eaſy of detection, by reaſon of the great ſeparation which takes place between the fragment and main part of the bone. The detached piece, alſo, does not move with the reſt of the ſcapula.

Fractures of the ſpine of the ſcapula are rendered manifeſt

by the irregularity which is generally produced in the courſe of that prominent proceſs. A crepitus is likewiſe perceptible.

When the body of the ſcapula is fractured, the nature of the accident is uſually made ſufficiently plain by the crepitus which takes place on moving the ſhoulder and arm.

Fractures of the body of the ſcapula are ſometimes comminuted; but, as the fragments are covered with muſcles on both ſides, they are hardly ever diſplaced.

The treatment of fractures of the ſcapula preſents the ſame indications which accompany fractures in general. In longitudinal and tranſverſe fractures of the body of the bone the ſurgeon has very little to do: a piece of the emplaſtrum ſaponis and ſome compreſſes ſhould be laid over the ſituation of the injured part, and be kept on with a ſpica bandage. The chief indication, however, is to maintain the broken bone in a motionleſs ſtate; an object which can only be accompliſhed, by preventing the arm itſelf from moving. Hence, it becomes neceſſary to confine the humerus cloſe to the ſide, by applying a roller round it and the body together, from the ſhoulder to the elbow.

We have remarked, that when the lower angle of the ſcapula is broken, the fragment becomes drawn downward and forward by the action of the ſerratus major anticus muſcle. Hence, it is proper to bring the ſcapula towards the ſeparated fragment, by bringing the arm itſelf downward and forward, in which ſituation it ſhould be confined with a roller. The fore-arm ſhould alſo be ſupported in a ſling, and the fragment of bone be kept as much upward and backward as poſſible, by means of proper compreſſes and a bandage.

When the acromion is fractured, the action of the deltoid muſcle tends to draw downward and outward the detached portion. The treatment conſiſts in raiſing the arm ſufficiently to make the head of the os brachii force the outer part of the acromion upward, at the ſame time that an aſſiſtant puſhes the ſcapula downward and forward, in the oppoſite direction to that in which the ſurgeon puſhes the arm. In this country, practitioners uſually apply a piece of the emplaſtrum ſaponis to the ſituation of the fracture, and then the ſpica bandage. But theſe latter proceedings are only for the ſake of appearances, and tend to no particular good. The grand object ſhould be to maintain the ſhoulder and arm in the poſition above deſcribed; and it may be effected by applying a roller round the arm and trunk together, and putting compreſſes and a bandage on the ſcapula.

There is an advantage, alſo, in making the head of the os brachii ſtand more out, on bringing the elbow cloſe to the ſide; and it was with this view that Deſault was in the habit of placing a ſmall pillow in the arm-pit, before he bound the arm and body together with the roller.

The treatment of fractures of the coracoid proceſs conſiſts in bringing the os brachii forward towards the ſternum, and placing the ſhoulder downward and forward, ſo as to relax the muſcles which have the power of diſplacing the fragment. The arm ſhould be kept in the poſition which we have ſpecified, by means of a ſling. A roller may be uſed for keeping the ſhoulder downward and forward, and ſome uſe may be derived from placing a compreſs juſt under the detached piece of bone.

When the neck of the ſcapula is fractured, the glenoid cavity and the whole of the upper extremity fall ſo much downward as to occaſion the appearance of a diſlocation. The plan which the ſurgeon ought obviouſly to follow in this caſe, is to raiſe the os brachii ſufficiently to bring the external piece of the neck of the ſcapula into contact with the internal one. The limb and glenoid cavity ſhould then be prevented from falling down again by ſupporting the elbow and fore-arm in a proper ſling. A piece of the emplaſtrum ſaponis and a ſpica bandage are next applied by the generality of practitioners. But a more uſeful ſtep is to prevent all motion of the ſhoulder and arm, by binding the os brachii cloſe to the ſide with a roller. Thus the fracture will be kept in a quiet ſtate, which is highly favourable to the union of all broken bones.

Fractures of the Humerus, or Os Brachii.

It is remarked by ſurgical writers that fractures of the humerus are very ſeldom diſplaced in the longitudinal direction, eſpecially when the ſolution of continuity is ſituated at the lower part of the bone. Here the brachialis internus and triceps muſcles, being attached to the humerus on all ſides, prevent both the fragments from becoming ſeparated. Circumſtances are different when the fracture happens above the inſertions of the deltoid and coraco-brachialis muſcles. If we conſider the action of theſe muſcles, and the manner in which the latiſſimus dorſi, pectoralis major, and other muſcles exert themſelves, we ſhall diſcover in ſuch powers many cauſes to diſplace the fracture, particularly when it is an oblique one, as is often the caſe.

All oblique fractures of the os brachii are generally diſplaced, whenever the part of the bone in which the ſolution of continuity has happened is above the middle. The upper ſurface of the fracture being then unfitted for making an effectual mechanical reſiſtance to the aſcent of the lower one, the latter eaſily glides upward and rides over the former, on being drawn in ſuch direction by the action of the deltoid, biceps, coraco-brachialis, and long portion of the triceps.

The humerus is ſubject to fractures at every part, from the head to the condyles of the bone. When the ſolution of continuity happens above the inſertion of the pectoralis major, latiſſimus dorſi, and teres major muſcles, ſurgeons call it a fracture of the neck of the humerus, an expreſſion which does not ſtrictly accord with the idea which anatomiſts give us, of what ought properly to be regarded as that part of the bone. The neck, in anatomical language, means the circular contraction which ſeparates the head from the tuberoſities; but ſeveral eminent writers on ſurgery imply by a fracture of the neck of the humerus any ſolution of continuity above the inſertion of thoſe particular muſcles which we have juſt been enumerating.

The general ſymptoms attendant on fractures of the humerus are, a change in the direction, and a ſhortening of the limb; a diſtinct crepitus on moving the lower portion of the broken bone; conſiderable pain, which is materially increaſed by every movement of the arm; the uſe of the limb is loſt, &c. The reader is already appriſed that when the fracture is ſituated low down, its ends will not ride over each other ſo as to ſhorten the member.

The diagnoſis of moſt fractures of the os brachii is ſufficiently plain: it is only when the neck of the bone is broken that any obſcurity is likely to prevail, and that there is any probability of miſtaking the caſe for a luxation of the ſhoulder. A little reflection will ſoon qualify any practitioner to avoid the error; for the differences of the two caſes are conſiderable.

Fractures of the neck of the humerus are attended with a depreſſion at the upper and outer part of the arm.

When the head of the bone is diſlocated into the axilla, a deep hollow may be felt immediately under the acromion, in the

the place which the head of the bone ought to occupy. The ſhoulder is not ſo prominent as natural, and the acromion ſeems to form a preternatural projection. The limb is alſo lengthened.

On the contrary, when the neck of the bone is fractured there is no alteration in the ſhape of the ſhoulder; the acromion does not appear to make any uncommon projection; there is no unuſual hollow immediately under it, and whatever depreſſion occurs, is ſituated lower down.

The limb, inſtead of being lengthened, is ſhortened; in the axilla, inſtead of the round, ſmooth head of the bone, the rough end of the lower fragment may ſometimes be felt; and added to all theſe circumſtances, there is that almoſt deciſive ſymptom, a crepitus.

Before proceeding to ſpeak of the treatment of fractures of the humerus, we ſhall make a few remarks on ſuch injuries, when they affect the lower end of the bone.

The inferior end of the os brachii is ſometimes fractured in ſuch a way, that a longitudinal ſolution of continuity divides the two condyles from each other, and, extending more or leſs upward, is bounded by another tranſverſe or oblique diviſion, which affects the whole thickneſs of the bone. Hence, there are three different pieces of bone, and two fractures.

In certain inſtances, fractures of the lower end of the os brachii are of a more ſimple deſcription; for the diviſion may be oblique, and run down in the direction outward, or inward, ſo as to extend acroſs one ſide of the lower end of the bone, and reach into the joint, thereby detaching only one of the condyles from the body of the bone. It is alſo poſſible for the internal condyle to be broken, without the fracture having any communication whatſoever with the cavity of the joint.

When the bone is ſo broken, as to be ſplit into three portions, with a ſeparation of both condyles, the deformity is greater, and the fractured part more moveable than in the other example. On making preſſure either on the front or back part of the joint, the two condyles become more diſtant from each other, and the injured part of the arm ſeems widened. The patient commonly keeps his fore-arm in a ſtate of pronation; and the practitioner, on taking hold of both condyles at once, and moving them in contrary directions, may feel a manifeſt crepitus.

When only one condyle is detached, the ſurgeon may alſo feel a grating on moving the ſeparated fragment; but the deformity is much leſs conſiderable.

In ordinary fractures of the humerus, the firſt duty of the ſurgeon is to put the ends of the broken bone into as even a poſition with regard to each other as circumſtances will allow. However, when the ſolution of continuity is tranſverſe and ſituated low down, the reader already knows that it often happens that the fragments are little if at all diſplaced.

It was once the cuſtom to place the arm at a right angle with the body; but this method, being found diſadvantageous, it was abandoned; and modern practitioners now univerſally give the preference to that poſition in which the arm lies in the direction of the trunk. Such poſture is found to be leſs irkſome to the patient, and the ends of the fracture are leſs apt to be diſturbed, ſince there is no occaſion to move the limb out of that poſition during the whole of the treatment.

It is cuſtomary, alſo, to adviſe the patient to go to bed, and to remain there for the firſt few days. As ſoon as the patient is in bed, no time is to be loſt before the ſurgeon ſets about reducing and putting up the fracture.

Abroad, ſurgeons direct one aſſiſtant to take hold of the wriſt and make the requiſite degree of extenſion, while another graſps the upper part of the os brachii, and the practitioner himſelf endeavours with his fingers to make the ends of the fracture lie as ſmoothly and evenly as poſſible. In this country we are in the habit of acting ſomewhat differently; for we bend the elbow-joint in the firſt inſtance, and apply our extenſion and counter-extenſion immediately to the lower and upper portions of the broken bone.

We muſt alſo remark that fractures of the humerus ſeldom require a violent degree of extenſion.

The fracture having been reduced and put into an even ſtate of coaptation, the next indication is to keep it quietly in ſuch condition, until a firm union of one portion of the bone to the other has taken place.

The means employed for this purpoſe are, a piece of the emplaſtrum ſaponis, a roller, ſplints well lined with ſoft pads, and a ſling for the ſupport of the fore-arm and hand.

The integuments in the vicinity of the fracture have commonly applied to them two pieces of the ſoap-plaſter, which together ought to extend all round the limb. This method is preferable to ſurrounding the part with one larger piece, which, in caſe of much ſwelling taking place, might not yield ſufficiently to prevent the unpleaſant conſequences likely to ariſe from any undue preſſure on, and confinement of, the member in this circumſtance.

The roller is next to be applied from the elbow up to the armpit, in the common way, the practitioner taking care not to make the bandage too tight; a thing which could do no good, and might be productive of pain and other bad effects.

It is plain that the preceding parts of the apparatus are more uſed for the ſake of neatneſs and appearances than for any particular efficacy. The moſt uſeful means are the ſplints and ſling.

Four ſplints are uſually employed; *viz.* one on the inſide; one on the outſide; one on the back; and another on the fore-part of the arm. The external one ſhould reach from the acromion to the outer condyle; the inner one, from the margins of the axilla to the internal condyle; the back one, from the head of the bone down to the olecranon; and the anterior one, from the ſame height down to the bend of the elbow. The bad conſequences of their preſſure on the ſoft parts are to be prevented, by placing betwixt the ſkin, and the inſide of the inſtruments, pads made of tow, or wool. Compreſſes ought alſo to be uſed for hindering the ends of the ſplints from chafing the margins of the axilla, or any other place where the patient feels uneaſineſs from a ſimilar cauſe.

Splints made with longitudinal joints, and lined with leather, are very good ones for fractures of the humerus. When the inſtruments are too long, and none of the proper ſhortneſs are at hand, the ſurgeon commonly cuts off as much of each ſplint which he ſelects as is neceſſary.

The ſplints being all arranged in their reſpective places, the practitioner maintains them ſo with three or four bits of tape, doubled into as many nooſes, applied at different parts of the limb, and tied in bows.

Many ſurgeons act very properly in not truſting entirely to tapes, which are apt to become ſlack after a little while, ſo as to allow the ſplints to ſlip and move about. Such practitioners, with great prudence, apply a roller over the ſplints, and then the tapes, if they are required.

As all motion of the elbow-joint, and of the radius, would produce a diſturbance of the fracture, it is neceſſary to lay the fore-arm in a ſling, and keep it perfectly at reſt. The ſling ſhould not preſs the elbow too forcibly upward, which,

in cafes of oblique fractures, would be apt to make the lower piece of the broken bone afcend and ride over the lower one.

We fhall now introduce a few obfervations on the treatment of fractures of the neck of the humerus.

Sometimes fractures of the neck of the humerus are not at all difplaced, and the diagnofis is confequently very difficult. However, in the generality of cafes, the lower end of the fracture is drawn out of its proper pofition, while the upper one continues quite undifplaced, being of little extent, and acted upon by few mufcles.

In ordinary inftances, the lower fragment is not materially difplaced in the longitudinal direction; though cafes do occur, in which the bone is confiderably out of its right fituation in this refpect. This happens when the fracture is exceedingly oblique, and the mufcles contract with unufual violence, and alfo when the force, which breaks the bone, continues to operate after the fracture, fo as to feparate the ends of the bone from each other. In "Les Oeuvres Chirurgicales de Default," it is faid, that in this manner the inferior end of the fracture has been driven through the deltoid mufcle and fkin of the fhoulder. According to Petit, the action of the mufcles is in general effectually refifted by the weight of the limb, and the fracture is only difplaced in the tranfverfe direction, inward or outward. In the firft cafe, which is the leaft frequent, the elbow is feparated from the trunk, and cannot be put near to it without pain. In the fecond cafe the elbow inclines towards the fide.

Default advifes the reduction to be made as follows: one affiftant is to fix the trunk, by drawing towards himfelf the oppofite arm. A fecond affiftant is to take hold of the fore-arm, in a ftate of half-flexion, placing one of his hands behind the wrift to ferve as a fulcrum, while the other is applied to the middle of the front of the fore-arm for the purpofe of preffing it downward, fo as to make the requifite extenfion.

In this way the reduction may be accompliftied with very little force, directed according as the lower fragment is difplaced inward or outward.

The indications in the treatment of fractures of the head or neck of the humerus are, to make the arm and fhoulder immoveable; to bring either outward or inward the lower end of the fracture, and to draw downward the fame. Thefe are the objects which every bandage ought to fulfil; but it fhould be underftood, that the laft purpofe is of the leaft importance, becaufe, in general, the weight of the arm is alone fufficient to counteract fuch mufcles as have a tendency to draw the lower end of the fracture upward.

The following was the apparatus, which the celebrated French furgeon, Default, was in the habit of employing with fuccefs for the cure of fractures of the above defcription.

1. Two bandages, one about five or fix ells long, the other eight or ten, both being about three finger-breadths wide. 2. Three ftrong fplints, of different lengths, and two finger-breadths broad. 3. A linen pillow, three or four inches thick at one of its ends, terminating at the other in a narrow point, and long enough to reach from the axilla to the elbow. 4. A fling to fupport the fore-arm. 5. A towel to cover the whole of the apparatus.

The reduction is to be effected as above explained, and the affiftants are to continue the extenfion. Then the furgeon is to take the firft roller, which is to be wet with the aq. veg. min. and is to fix one of its heads by applying two circular turns to the upper part of the fore-arm. The bandage is now to be rolled moderately tight round the arm upward, making each turn overlap two-thirds of that which is immediately below it. When the roller has reached the upper part of the limb, it muft be doubled back a few times to prevent the folds which the inequality of the part would create. The bandage is afterwards to be carried twice under the oppofite axilla, and the reft of it, rolled up, is to be brought up to the top of the fhoulder, and committed to the care of an affiftant.

The firft fplint is to be placed in front, reaching from the bend of the arm as high as the acromion. The fecond, on the outfide from the external condyle to the fame height. The third, behind, from the olecranon to the margin of the axilla. The pillow interpofed between the arm and thorax ferves as a fourth fplint, which becomes ufelefs. An affiftant applies thefe parts of the apparatus, and holds them on by applying his hands near the bend of the arm, in order not to obftruct the application of the remainder of the bandage.

The furgeon takes hold of the bandage again, and applies it over the fplints with moderate tightnefs, and the bandage ends at the upper part of the fore-arm, where it began.

The affiftants continually keeping up the extenfion, the furgeon is to place the pillow between the arm and trunk, taking care to put the thick end upward, if the fracture be difplaced inward; but downward, if this fhould be difplaced outward, which is moft common. It is to be attached by two pins to the upper part of the roller.

The arm is to be brought near the trunk, and fixed upon the pillow, by means of the fecond roller, applied round the arm and thorax. The turns of this bandage fhould be very tight below, and rather flack above, if the fracture fhould be difplaced inward: but, if outward, they fhould be flack below and tight above.

The fore-arm is to be fupported in a fling, and the whole of the apparatus is to be covered with a napkin, which will prevent the bandages from being difplaced.

Fractures of the lower end of the os brachii were regarded by Paré, Petit, Heifter, Duverney, and feveral other furgical authors, as very apt to be attended with alarming confequences, large abfceffes, gangrenous mifchief, caries, anchylofis, &c.

The experience of Default affords ample proof, that the foregoing evils are not fo likely to happen, as former furgeons believed, at leaft under judicious treatment.

We know, that every fracture near a joint is not invariably dangerous, nor productive of permanent inconveniences. The refult of fractures of the patella and olecranon, cafes which are particularly common, ought to inform us, that, though fractures near joints, fometimes, have a difagreeable termination, they frequently end in a very favourable manner. Compound fractures of any large joints, however, may be juftly looked upon as cafes of the moft dangerous defcription; they often require the performance of amputation immediately after the accident.

When the lower end of the os brachii is fractured, the detached condyle, or condyles, are fometimes difplaced; but, in general, the feparation is not confiderable, owing to the fragments being drawn in oppofite directions by the mufcles of the arm and fore-arm, which powers counteract each other. Whenever the feparation is wide, it is the direct of the external violence.

The condyles may be difplaced forward, or backward, or they may recede from each other fideways.

From this account it is plain, that the object of the apparatus fhould be to prevent the fragments from being difplaced in thefe four directions.

The

The fracture having been reduced, and ſome of the emplaſtrum ſaponis applied, a roller ſhould be put round the part, and then round the fore-arm, in order to make gentle compreſſion on the muſcles inſerted into the condyles. Such preſſure, Default believed, diminiſhed the power of the muſcles in acting upon, and diſplacing the parts. The ſame diſtinguiſhed ſurgeon next adviſes the application of four ſplints, one in front of, one behind, and two others to the ſides of the arm. He thought that there was no utility in having the ſplints to extend very high up the arm, in this particular caſe. The anterior and poſterior ſplints he recommends to be made flexible at their middle part, which is to be put oppoſite the elbow-joint, ſo as to allow it to be in a ſtate of flexion, at the ſame time that they reach for a certain extent down the fore-arm.

We need ſcarcely remark, that the fore-arm muſt alſo be kept at reſt in a ſling.

Fractures of the Olecranon.

The ancients have not left us any remarks of importance concerning fractures of the olecranon, and ſeveral modern writers appear to have been very imperfectly acquainted with the ſubject.

Putting out of conſideration pronation and ſupination, which have little connection with the preſent caſes, we may obſerve that the elbow is a joint admitting of flexion and extenſion, for which purpoſes, the rounded and pulley-like extremity of the os humeri is received, and moves in a correſponding cavity of the ulna, called *ſigmoid*. The two proceſſes, by which this cavity is in ſome degree formed, are its anterior, called *coronoid*, and its poſterior, called *olecranon*. In order the better to regulate the degree of flexion and extenſion, there are two cavities, ſituated at the inferior extremity of the os humeri; one on the anterior, the other on the poſterior ſurface; into theſe the two proceſſes of the ulna are occaſionally received. When the joint is in the greateſt degree of flexion, the coronoid proceſs is received into the anterior cavity; and, when in the greateſt degree of extenſion, the extremity of the olecranon occupies the poſterior cavity.

In order to communicate motion to this arrangement of parts, muſcles are ſituated in various directions; but the muſcle, by which extenſion is chiefly performed, the triceps extenſor cubiti, being inſerted into the extremity of the olecranon, has an attachment peculiarly advantageous and mechanical, as it is thereby at ſome diſtance from the centre of motion, conſequently, leſs exertion will be neceſſary to accompliſh extenſion.

When by any accident the olecranon is broken off, two very important changes are induced. Firſt, the lever, which enabled the muſcle to act ſo advantageouſly, is removed. Secondly, the ſpace, in which the muſcle acted, is now ſhortened. Hence, that bony arrangement, that was before ſo favourable to motion, is now deſtroyed; and the muſcle, by whoſe agency ſuch motion was performed, has its power conſiderably leſſened. See ſome remarks by Haighton in the ninth volume of the Medical Commentaries, p. 382.

Fractures may occur either at the baſe, or the extremity of the olecranon. The firſt kind of caſe is the moſt common. The ſolution of continuity is ſometimes oblique, though, generally, tranſverſe. The accident is uſually occaſioned by external violence; but, in certain inſtances, the proceſs is torn off by the violent action of the powerful muſcle, which is attached to it.

The following deſcription of the ſymptoms of this fracture will enable any practitioner to detect what has happened with equal eaſe and certainty. The contraction of the triceps, being no longer reſiſted by any connection with the main portion of the ulna, this muſcle pulls upward the ſmall piece of bone broken off, ſo as to produce an interſpace between ſuch fragment and the reſt of the bone. The interſpace is ſituated at the back part of the joint, and may be increaſed, or diminiſhed, by ſimply augmenting the bent, or extended ſtate of the fore-arm. The patient cannot ſpontaneouſly extend his fore-arm, owing to the connection of the triceps with the ulna being deſtroyed. Whether the anconæus alone may be adequate to accompliſh this motion in certain examples, we will not take upon us to decide; but, certain it is, the fore-arm is always found in a half-bent ſtate, in conſequence of the flexor muſcles not having any conſiderable antagoniſt. The detached portion of the olecranon becomes drawn higher up than the condyles of the os humeri, whereas, in the natural ſtate, the latter proceſſes are ſituated higher than the point of the olecranon, when the fore-arm is in a ſtate of half-flexion. The fragment of bone may be moved in any direction, without any motion being imparted to the ulna. When the fore-arm is extended, and the ſurgeon puſhes down the retracted piece of bone, a grating or crepitus generally admits of being felt.

We may alſo remark, that this accident, like moſt other fractures, is attended with a good deal of pain, and the ſoft parts ſoon become affected with conſiderable ſwelling.

In the Pariſian Chirurgical Journal, vol. i. are ſome obſervations on the Treatment of the Fractures of the Olecranon: ſome of theſe we ſhall take the liberty of introducing into this work.

The ancients have tranſmitted to us nothing on fractures of the olecranon, unleſs we admit that Paulus Eginetus has made alluſion to them in the following paſſage: "Cubitus frangitur—circa partem ad cubiti gibbum." (De Re Medicâ, lib. 6. cap. 100.) The moderns, and even Petit himſelf, have not diſtinguiſhed this from other fractures of the ulna. The majority of practitioners, miſled by a falſe theory, and perſuaded that loſs of motion was neceſſarily conſequent to all fractures, connected with the articulations, did not even attempt its reduction. They kept the arm in a ſling in a flex poſition, in order that the anchyloſis might be as little inconvenient as poſſible. And what tended to confirm them in their error was, that the powers of extenſion were totally loſt by the obſervance of the extended poſition, and in conſequence of the muſcles remaining for ſuch a length of time in a ſtate of inaction.

Duverney is the firſt who has propoſed a methodical treatment for this accident. (Mal. des Oſ. tom. i. p. 325.) This fracture, he ſays, is to be diſtinguiſhed by the circumſtance of the fractured portion being drawn up by the actions of the extenſor muſcles, and the impoſſibility of moving the fore-arm, which reſts hanging by the ſide of the body. He accompliſhes the reduction by extending the fore-arm, puſhing down the proceſs of the olecranon with his thumbs, and retaining it in this ſituation by means of a thick narrow compreſs placed above the fracture. A circular compreſs, and a bandage like that uſed in bleeding, are then applied over the former application. The limb, ſlightly bent, was next laid on a pillow; and, at the expiration of a few days, an endeavour was made to prevent an anchyloſis by gentle and repeated motion.

M. David attributes the anchyloſis, which often followed fractures of the olecranon, to the ignorance of the ſurgeon Reſt and extenſion, he thinks, eſſentially neceſſary to the reunion; but as ſoon as this has taken place, which is generally about the twenty-fifth day, he recommends the arm to be gently moved, and this motion to be increaſed every day.

He obſerves, alſo, that if the arm be extended too much, the extremity of the ulna will be forced in, and the union will either be imperfect, or the motions of the joint attended with difficulty. Diſſert. ſur les Effets du Mouvement, &c. p. 63, &c.

It is ſtated in the Pariſian Chirurgical Journal, that, before the time of its publication, the ſubject of fractures of the olecranon had not been duly conſidered. Duverney's method was ſubject to many inconveniences: his compreſſes, bandages, &c. could eaſily be diſplaced; and he applied nothing to prevent the flexion of the fore-arm. When the bandage was too looſe, the olecranon could not be retained in its ſituation; and when it was too tight, much ſwelling was induced.

The following was Default's plan, which does not materially differ from the mode followed in this country, and appears to us judicious and deſerving of imitation.

While the aſſiſtants extend the fore-arm, one turn of a ſingle-headed roller, moiſtened with the ſaturnine lotion, is to be applied round the wriſt, and continued over the whole fore-arm as high as the bend of the elbow. The fractured olecranon is to be drawn down towards the ulna, while the ſkin is pulled upward by an aſſiſtant, ſo as to prevent it from being wrinkled. When this caution is overlooked, ſome folds of the integuments are apt to get between the diſunited parts, and prove an impediment to the re-union. When the finger is removed, which is employed for preſſing the olecranon againſt the ulna, the fragment of bone is to be kept in its proper ſituation by a turn of the roller, which is to be carried from the upper and front part of the fore-arm above the elbow, and then on the inſide of the limb. The roller is now to be reflected back again on the anterior part of the fore-arm, ſo as to make a bandage in the ſhape of a figure of eight, ſimilar to what is uſed after bleeding. The application of the roller is to be continued as high as the upper part of the arm, where it is to be fixed by a circular turn.

A ſtrong ſplint is next applied to the whole length of the arm and fore-arm. The inſtrument is to be a little bent at the joint, in order to prevent the complete extenſion of the fore-arm; by which means, according to Default, the end of the fractured ulna would be forced into the cavity of the olecranon, and puſhed more forward than the other fragments, ſo as to render the union irregular.

The ſplint is to be retained with the reſt of the roller, and the limb laid on a pillow, in ſuch a way that the preſſure may be every where equal.

When the bandage grows ſlack, in conſequence of the ſubſidence of the ſwelling, it is to be taken off and re-applied.

At the end of three weeks, the ſplint may be left off, and a roller alone uſed for keeping the limb extended a few days longer. All bandages may now be omitted, and the ſurgeon ſhould accuſtom the patient to bend and extend the joint for a certain time every day.

We have never ſeen any ill effects ariſe from keeping the fore-arm quite extended; but, ſhould it be deemed proper to keep the limb a little bent, and ſhould no ſplint like that recommended by Default be at hand, the ſurgeon might make a ſtraight one anſwer the purpoſe, by filling up the ſpace under the middle of the ſplint, in front of the elbow-joint, with a proper-ſhaped pad, made with tow, or any other ſoft material.

It ſometimes happens, that one of the bones of the fore-arm is broken, together with the olecranon; and, as it is uſual to bend the limb in the treatment of the firſt injury, and extend the arm for the cure of the ſecond, the practitioner may be thrown into embarraſſment by meeting with a caſe of this deſcription.

The matter, however, is very ſimple. Bending the arm is not eſſential for the cure of fractures of the radius or ulna, but is abſolutely requiſite for uniting the broken olecranon, ſo as to prevent future lameneſs. Hence, the proper method is to keep the limb in a ſtraight poſition, and pay attention to both accidents. We have, in this manner, cured a caſe of fractured olecranon and radius with the utmoſt ſucceſs. It ſhould alſo be noticed, that this practice was what the eminent Default was in the habit of following, and adviſing in his lectures.

Fractures of the Fore-arm.

The fore-arm is particularly often the ſituation of fractures; and this circumſtance is aſcribable both to the way in which the radius and ulna are expoſed to direct external violence, and to the manner in which every force applied to the hand is tranſmitted to the former of theſe bones. Hence it happens, that fractures of the radius are much more frequent than thoſe of the ulna; but the conjoined number of theſe accidents, with regard to the two bones, appears, from a comparative table kept at the Hôtel-Dieu, in the time of Default, to equal, or rather exceed, the number of fractures affecting any other part of the body.

In ſome inſtances, we find both the bones of the fore-arm broken together; while, on other occaſions, only one bone is injured.

Fractures of both Bones of the Fore-arm.

The accident may take place near the elbow, or wriſt, or at the central part of the limb. The latter ſituation is that in which fractures happen moſt frequently; they alſo often occur towards the wriſt, but ſeldom near the bend of the arm. In this laſt ſituation, the thickneſs and ſtrength of the ulna, and the manner in which the bones are covered and protected by numerous muſcles, neceſſarily render the accident uncommon. We do not wiſh, however, to make the reader imagine that the upper part of the fore-arm is totally out of the danger of fractures. It has, indeed, never been our lot to meet with an example, in which the radius and ulna have been broken together, in this high ſituation; but there can be no doubt that ſuch an accident is poſſible, and might ariſe from the paſſage of the wheel of a cart or carriage over the limb. We have, in two or three inſtances, ſeen the upper end of the radius broken off.

When both the bones of the fore-arm are fractured, the ſolution of continuity generally runs in the ſame line. However, this is not invariably the caſe.

It does not often happen that fractures of this part of the body are either compound or comminuted. Both kinds of caſes may preſent themſelves in a large field of practice; but ſurgeons of circumſcribed experience are not very likely to meet with them. Default had under his care a patient, whoſe radius and ulna were both broken in two places, by the paſſage of a cart-wheel over the limb: the deformity remaining after the cure was exceedingly trivial.

A fracture of both bones of the fore-arm is generally occaſioned by ſuch a force as operates directly on the broken part. The accident hardly ever originates from a fall on the hand; in which occurrence, the external violence generally only affects the radius, which alone becomes fractured.

Fractures of the radius and ulna together are very eaſily diſtinguiſhed. The ſurgeon finds the limb capable of being bent at a part, which was previouſly firm, ſtraight, and unyielding.

unyielding. On taking hold of the limb, he readily feels a crepitus, or grating of the ends of the fracture. In certain caſes, there is a manifeſt depreſſion where the ſolution of continuity has happened; in other inſtances, a prominence formed by the extremities of the fracture. Handling and moving the injured part excite a ſevere degree of pain. The patient is unable to execute the pronation and ſupination of the hand, and is almoſt always found with his elbow-joint half bent.

A miſtake may indeed be made, when both bones are fractured very near the wriſt; in which ſort of caſe, the practitioner may erroneouſly conclude that there is a diſlocation. The way to avoid forming a wrong judgment is to pay attention to the ſituation of the ſtyloid proceſſes, in relation to the deformity. When they are above it, and remain motionleſs on moving the carpus, the caſe is a diſlocation; when they are below the deformed part, and move about with the hand and wriſt, the accident is a fracture. In the latter inſtance, alſo, a crepitus may generally be felt, and the injured part is more moveable than in the example of a luxation.

The deformity attendant on fractures of both bones of the fore-arm can never take place, in any very conſiderable degree, in the longitudinal direction. The manner in which the interoſſeous ligament is connected with the four ends of the fracture, forms an impediment to any material ſhortening of the fore-arm. A tranſverſe kind of deformity is apt to occur, which ariſes from the ends of the broken bones inclining towards the centre of the limb, ſo as to leſſen the breadth of, what might be called, the interoſſeous ſpace.

What the French ſurgeons name an angular deformity is alſo produced, either forward or backward, according to the direction of the force which occaſioned the fracture.

The treatment of a fracture of both bones of the fore-arm is to be conducted in the following manner: The ſurgeon is, in the firſt place, to bend the fore-arm to a right angle with the arm, and put the hand in the middle ſtate between pronation and ſupination. An aſſiſtant is now to take hold of the patient's four fingers, and make the neceſſary degree of extenſion; while another aſſiſtant makes the requiſite counter-extenſion, by fixing the lower part of the os brachii with both his hands. The ſurgeon ſhould now endeavour to put the ends of the fracture in an even ſtate of coaptation; and, above all things, he ſhould try to reſtore the due width of the interoſſeous ſpace, by gently preſſing the ſoft parts into it.

We have to remark on this ſubject, that fractures of the fore-arm may generally be ſet with great facility, and without the exertion of much force in the extenſion.

Engliſh practitioners, as ſoon as they have reduced the fracture, next put a piece of ſoap-plaſter round the injured part, and then apply a roller to the fore-arm, from the hand to the elbow.

In all caſes in which the radius is broken, a roller ought never to be put on with tightneſs, becauſe the preſſure can be of no ſervice, and may do irremediable miſchief, by forcing inwards the extremities of the fractured radius towards the interoſſeous ſpace. Thus the bone may be made to unite in a very deformed way, and the pronation and ſupination of the hand may be utterly deſtroyed.

The fracture having been put in a ſtate of coaptation, and a piece of the emplaſtrum ſaponis applied together with a roller, the next object is to place the fore-arm in ſplints, ſo as to preſerve the broken bones in their right poſition until they have grown together again. The practitioner taking care to have the ends of the fracture as evenly in contact as poſſible, is to apply two ſplints; one is to extend from the bend of the arm to the middle of the fingers, the other is to reach from the outer part of the elbow to the ends of the metacarpal bones. Both theſe inſtruments are to be lined with pads of ſoft materials. What are termed jointed ſplints are not eligible for fractures of the fore-arm, becauſe they tend to preſs the broken bones too much towards the centre of the limb, ſo as to diminiſh the interoſſeous ſpace.

We muſt alſo caution ſurgeons not to employ too long a ſplint on the inſide of the arm; for experience proves that when the fingers are kept completely extended during the whole treatment, they are ſometimes a very conſiderable time in regaining a freedom of motion. The beſt plan is not to let the ſplint extend further than the point above ſpecified, and the fingers will then naturally continue a little bent. When the ſplints have been arranged, they are to be fixed in their reſpective ſituations with a roller, which executes this office much more ſecurely than pieces of tape.

Laſtly, the fore-arm is to be placed in a ſling, which ſhould always ſupport the limb from the elbow to the extremities of the fingers. Although every perſon, whether a ſurgeon or not, fancies himſelf capable of putting on a ſling, the fact is, that many practitioners of extenſive buſineſs are groſsly ignorant of the proper way in which this common and moſt uſeful bandage ought to be arranged. We daily ſee people with broken arms, ſprains of the wriſt, whitlows, &c. walking about the metropolis with ſlings, which juſt ſupport the hand, and leave all the reſt of the limb ſwinging and moving about. Since all the foregoing caſes demand quietude, the neglect to make the ſling ſupport the limb equally from the elbow to the fingers muſt be productive of ſerious harm, independently of the irkſomeneſs which a patient always feels, who has his fore-arm kept for a long while in a ſlovenly bandage of this deſcription.

Fractures of the Radius.

The radius is much more frequently broken than the ulna, on account of its ſituation expoſing it more to external violence, and its having to bear all the ſhocks communicated to the hand.

When a perſon has fallen with his hand upon the ground with conſiderable violence, and immediately afterwards experiences an inability of performing the pronation and ſupination of the hand, there is great reaſon for ſuſpecting that the radius is fractured. The ſurgeon however may eaſily aſcertain the accident by examining the courſe of the radius with his fingers; or, by laying the fingers of his left hand on the upper part, or middle of this bone, while with his right hand he moves the hand and lower portion of the ſame bone alternately in the prone and ſupine direction, ſo as to make the ends of the fracture rub againſt each other, and give the ſenſation of a crepitus or grating.

The diagnoſis in moſt fractures of the radius is plain and eaſy. However, a little obſcurity is apt to prevail, when the bone is broken very high up near its tubercle, becauſe here the fracture lies under the muſcles ariſing from the external condyle. In order to detect the accident, the beſt plan which the practitioner can follow in this circumſtance, is to place his thumb juſt under the external condyle of the os humeri, upon the upper round head of the radius, and then move the hand in the prone and ſupine directions. When the head of the bone continues motionleſs on making the experiment, and the patient complains of a good deal of pain, the ſurgeon may be ſure that the upper part of the radius is fractured. A crepitus alſo may generally be diſtinguiſhed.

Fractures of the radius can hardly be diſplaced in the longitudinal direction, on account of the manner in which the ends of the bone are attached to the ulna by means of the interoſſeous ligament. The derangement is commonly of the tranſverſe kind, which conſiſts of an approximation of the ends of the fracture to the ulna.

In fractures of the radius, it is obſerved, that the hand falls prone with much pain, becauſe the weight of this part of the limb makes the carpal bones and lower head of the radius turn on the ſmall head of the ulna, while the upper portion of the broken bone remains motionleſs, the ends of the fracture conſequently becoming ſeparated, and the ſoft parts injured. C. Bell's Operative Surgery, p. 184. vol. ii.

Fractures of the radius are to be treated in the ſame manner as fractures of both bones of the fore-arm. An endeavour muſt be made to keep the ends of the bone from inclining too much towards the centre of the limb. The fore-arm ſhould be put in the mid-ſtate between pronation and ſupination; and particular care ought always to be taken to employ an inner ſplint of ſufficient length to reach the fingers, keep the hand ſteady, and hinder it from falling into the prone poſition.

Fractures of the Ulna.

Fractures of this bone are much leſs common than thoſe of the radius, and are generally produced by direct violence, that is to ſay, by a blow, a kick, or a fall on the part. The radius, we know, is often broken by a force which is applied to the hand, but when the ulna is fractured, the accident is almoſt always produced by ſome violence which is applied immediately to the injured bone.

The lower end of the ulna is moſt liable to be broken, becauſe it is the moſt ſlender, and the leaſt covered with fleſh.

Fractures of the ulna are not apt to be ſo materially diſplaced as thoſe of the radius. The diagnoſis is alſo not ſo plain as in the latter caſes, and indeed when the ſolution of continuity is towards the elbow, great attention is required to diſcover what has happened. The ſurgeon ſhould trace with his fingers the ſuperficial parts of the bone, in order to find out whether there is any irregularity, and he ſhould preſs with his two thumbs above and below any ſuſpected point, for the purpoſe of feeling a crepitus.

The upper part of the ulna is never diſplaced, the lower one alone can be ſo.

A very little extenſion is generally requiſite for the reduction of either a fractured radius or ulna.

The treatment reſembles what has been adviſed for caſes in which the two bones are broken together.

Fractures of the Carpus, Metacarpus, Fingers, and Thumb.

The ſhape of the carpal bones, and the great quantity of cartilage which is placed around them, are circumſtances rendering them little liable to be broken, except by the effect of fire-arms, and by ſuch external violence as cruſhes theſe bones, as it were, and does infinite miſchief to the ſoft parts.

The metacarpal bones are alſo not frequently fractured; but the accident is every now and then met with in practice.

With reſpect to the treatment of fractures of the carpus, we have little to ſay, becauſe the injury of the bones is of much leſs importance than that miſchief, which the ſoft parts have generally ſuſtained from the violence which produced the accident. Amputation will ſometimes be more proper than any attempt to ſave the limb. In other caſes the fore-arm and hand may be laid on a flat ſplint, lined with a ſoft pad. The wound muſt be dreſſed or poulticed according to circumſtances, and the limb kept quiet in a ſling.

When any of the metacarpal bones are fractured, a cuſhion or pad ſhould be placed in the hollow of the palm of the hand and fingers. A roller is then to be applied from the fore-arm down over the wriſt, the hand, and the pad.

The fingers are alſo liable to fractures. Theſe caſes, under proper treatment, generally terminate very favourably, without leaving behind the leaſt impairment of the parts. After putting the pieces of bone into as even a ſtate as circumſtances will allow, the ſurgeon ſhould take ſome paſteboard ſoftened in vinegar, and accurately encloſe the broken part in it. Some tape may then be applied for the purpoſe of retaining the paſteboard in the proper place. Certain ſurgeons next lay the hand and fingers on a flat ſplint, and put on a roller, ſo as to keep the parts from moving. The fore-arm and hand ſhould be put in a ſling.

After ten or twelve days, the applications ſhould be taken off every day, and the finger bent and extended a certain number of times, in order to prevent anchyloſis.

At the end of three weeks, the paſteboard, bandages, and ſplint may be diſuſed.

In regard to fractures of the thumb, we need only remark, that they are very eaſily detected, and demand the ſame treatment as ſimilar injuries of the fingers.

We have ſeen a fracture of the metacarpal bone of the thumb. The accident occurred to a porter, who fell backward with a load. The hand was kept on a finger-ſplint, on which was put a tow-pad of ſufficient ſize to fill the hollow of the palm. A piece of the emplaſtrum ſaponis was put over the injured part, the limb was confined on the ſplint with a common roller, and the fore-arm and hand kept at reſt in a ſling.

The caſe united very favourably, but the union was not firm before the end of a month.

Fractures of the Thigh-bone.

The os femoris may be broken at any point, from its condyles below, to its round head above. However, experience evinces that by far the greateſt number of fractures happen to the middle third of the bone.

Fractures of the thigh-bone are divided by writers into ſimple and compound, comminuted and complicated, tranſverſe and oblique, &c.

It was an obſervation made by Petit, that the os femoris was much leſs frequently broken into ſeveral pieces than other more ſuperficial bones. We may alſo remark that compound fractures of the thigh, like comminuted ones, are by no means common caſes.

The tranſverſe and oblique directions of the ſolution of continuity are circumſtances which make a material difference in the degree of difficulty attending the treatment, as the reader will preſently underſtand. Tranſverſe fractures are by far the leaſt troubleſome to unite, without any deformity being occaſioned.

The ſymptoms and changes produced in the limb by a fracture of the thigh-bone, are of the following deſcription. A very ſevere pain in the ſituation of the injury greatly exaſperated when the muſcles are ſeized with violent involuntary contractions, or when the member is at all moved by the ſurgeon. Such pain is no doubt excited by the manner in which the rough, ſharp ends of the fracture muſt irritate and injure the ſurrounding ſoft parts. The practitioner may uſually feel a plain crepitus on bringing the extremities of the fracture into contact, and then moving them. He alſo

may

may generally ſee that a part of the limb bends, which naturally is quite firm and inflexible.

However, the principal changes, reſulting from the ſolution of continuity of the bone, are four ſpecies of deformity affecting the limb.

The firſt kind is that which ſhortens the member, and is called longitudinal. It takes place in conſequence of the aſcent of the lower portion of the broken bone, behind the upper piece, in the direction towards the tuberoſity of the ilium. This riſing of the lower piece of the os femoris is immediately cauſed by the contraction of ſuch muſcles as originate from the bones of the pelvis, and are inſerted into ſome part of the limb below the fracture. Computing that the majority of theſe accidents affect the middle third of the bone, it follows that the chief muſcles in queſtion are the triceps, ſemi-membranoſus, ſemi-tendinoſus, biceps, rectus, gracilis, and ſartorius, moſt of the other powers, deſtined to move the thigh bone, being attached to it much above the place where moſt fractures are ſituated.

However, when the fracture happens higher up than the common ſituation, an additional number of muſcles, and a larger quantity of muſcular fibres can act upon the portion of the os femoris below the fracture, ſo as to draw up the leg, knee, and lower part of the thigh with a proportionate increaſe of force. Hence it happens, when fractures of the thigh are high up the bone, there is always more ſhortening of the limb, and the ſurgeon experiences more difficulty in preventing this effect than in other inſtances.

It muſt be obvious, alſo, to every one endued with common ſenſe and an ordinary degree of reflection, that, as the ſurfaces of oblique fractures do not, like thoſe of tranſverſe ones, mutually reſiſt the paſſage of one beyond the other, but glide over each other as ſoon as the muſcles having the above-deſcribed power begin to act, oblique fractures muſt always be much more ſubject than tranſverſe ones to a ſhortening of the limb.

That the muſcles do occaſion the aſcent of the lower portion of the broken bone, muſt be manifeſt to every body who knows that the bones are paſſive parts, capable of no motion of themſelves, and deſtined to be acted upon and moved by other powers. Were it neceſſary to adduce any other argument to convince the undiſcerning and ſceptical, we might advert to the caſe related in "Les Œuvres Chirurgicales de Deſault," where the os femoris was fractured in a man, whoſe lower extremities were paralytic, and conſequently, whoſe muſcles were incapable of action. As long as this ſtate continued, the limb was not at all ſhortened; but no ſooner was the palſy removed by the application of the moxa, than the muſcles reſumed their power, and the lower part of the thigh, together with the knee, leg, and foot, became drawn up towards the pelvis, as in ordinary caſes.

When the limb is placed in the ſtraight poſition, the weight of the pelvis, and the prominence of the buttocks, ſoon make the bedding ſink, in conſequence of which circumſtance, the ſurface of the bed is made to ſlope in ſuch a manner that the patient's body ſlips from above downward, and puſhes before it the upper end of the fracture.

This occurrence augments the firſt kind of deformity often attendant on oblique fractures of the thigh, by ſhortening the limb in the longitudinal direction, and tending to make the ends of the fracture ride over each other.

The ſecond ſpecies of deformity, frequently ſeen in caſes of fractured thighs, is what is termed tranſverſe. It always accompanies the longitudinal deformity; but in certain inſtances it may be preſent alone. We need hardly obſerve that the word tranſverſe here means in the direction of the diameter of the bone, from any one point of the circumference to an oppoſite correſponding one. The tranſverſe diſplacement of a fractured thigh may take place without any longitudinal deformity, when the fracture is tranſverſe, and when one end of it is carried in one direction, while the other is drawn in the oppoſite one; or when one end of the fracture continues unmoved while the other ſeparates from it. In this circumſtance, the upper end of the fracture is not, as in the firſt kind of deformity, unaffected by the contraction of the muſcles; but, by being drawn out of contact with the lower portion of the bone, in conſequence of the action of the pectineus, pſoas, iliacus internus, and upper part of the triceps, it contributes to the tranſverſe kind of deformity.

The third ſpecies of deformity, ſometimes accompanying a fracture of the thigh, is what has been named angular, becauſe the two portions of the broken bone are made to form an angle with each other. It may be produced by the violence which cauſed the fracture, the awkwardneſs of the aſſiſtants in holding the limb, or by laying the member in an improper poſture.

The fourth and laſt ſpecies of diſplacement to which fractures of the thigh-bone are liable, is what may properly be denominated rotatory, becauſe the lower piece of the broken bone is by it turned, either inward or outward, on its own axis. The rotation outward is exceedingly common, and claims the particular attention of the ſurgeon in the treatment. If it is overlooked, the patient is for ever afterwards afflicted with a diſtortion of the toes outward, a turning of the inſide of the foot forward, and a loſs of the proper uſe of the kind of tripod which is naturally conſtructed in our feet, by the os calcis and balls of the great and little toes.

We ſhall now conſider the treatment of fractured thighs, a ſubject highly intereſting, and even at this day involved in controverſies. When we inform our readers that Pott is an advocate for one plan, and Deſault for an oppoſite one; that many Engliſh ſurgeons place the limb in a bent poſition, and that all or nearly all foreign practitioners prefer the ſtraight one; it muſt be manifeſt that prejudice and error influence one ſet of partiſans or the other, as it is impoſſible that one mode of treatment ſhould be exactly as eligible as the other.

In the general remarks at the beginning of this article, we have noticed Mr. Pott's opinions reſpecting the advantages to be derived from the relaxation of the muſcles connected with broken bones. We already know that this eminent ſurgeon conceived that a broken thigh might be laid in ſuch a poſture as would relax the whole of the muſcles belonging to the injured part of the limb.

In enforcing his precepts, and endeavouring to point out what muſt beſt anſwer the purpoſe of incapacitating the muſcles from diſplacing the fracture, he obſerves: "is it not obvious that putting the limb into ſuch poſition as ſhall relax the whole ſet of muſcles belonging to or in connection with the broken bone, muſt beſt anſwer ſuch purpoſe?" Pott's works, vol. i. p. 389. edit. 1783. Alſo, in the next page, it is enquired, "what is the reaſon why no man, however ſuperficially acquainted with his art, ever finds much trouble in ſetting a fractured os humeri? Is it not becauſe both patient and ſurgeon concur in putting the arm into a ſtate of flexion, that is, into ſuch a ſtate as relaxes all the muſcles ſurrounding the broken bone?" Alſo, in page 393, Mr. Pott continues: "change of poſture muſt be the remedy, or rather the placing the limb in ſuch manner as to relax all its muſcles."

That to have all the muſcles relaxed in caſes of fractures,

would be deſirable were it alſo practicable, every one will admit; but, the poſſibility of accompliſhing it, ſo long as different muſcles have different uſes, different ſituations, and different attachments to the bones, every one muſt grant to be no more than viſionary. For inſtance, do not the patient and ſurgeon in the caſe of fractured os humeri, adverted to above, rather concur in putting the fibres of the triceps and anconeus into a ſtate of tenſion, at the ſame moment that they relax the biceps and brachialis internus? The true reaſons why a fractured arm generally unites favourably without much difficulty, might be more properly referred to circumſtances mentioned in our obſervations on this caſe.

The ſmall number of muſcles; the manner in which theſe counteract each other; the way in which the weight of the lower portion of the broken part of the limb makes a permanent, though not a conſiderable, oppoſition to the aſcent of the inferior fragment; the eaſe with which the fore-arm may be kept in a quiet ſtate, in compariſon with the difficulty of maintaining the leg in this condition during the treatment of a fractured thigh, &c. are cauſes ſatisfactorily ſhewing why there ſhould be little trouble in the cure of the former caſe, and often a great deal in the management of the latter.

We have heard ſome perſons, who do not undertake to defend the imperfect explanations of Pott, argue, that the half-bent poſition of the limb is the beſt, and that as it is the poſture which the limbs aſſume during ſleep, it is the moſt eaſy.

Richerand, in his Noſographie Chirurgicale, tom. ii. denies that the bent poſture is the leaſt irkſome; and, as far as our obſervations extend, patients always make more complaint at being compelled to lie, for a long while, in the ſame poſition on their ſide, than of being neceſſitated to continue for an equal length of time on their backs.

With regard to the queſtion, which poſition relaxes the greateſt number of muſcles capable of diſturbing the coaptation of a broken thigh, we ſhould maintain that the bent poſture effects this deſirable object. It more or leſs relaxes the triceps, ſemi-membranoſus, ſemi-tendinoſus, biceps, gracilis, and ſartorius muſcles, which can all contribute in a very powerful degree to draw up and diſplace the lower portion of the broken bone.

However, the moſt ardent advocates for the bent poſition will always be obliged to acknowledge, that it leaves a ſufficient quantity of muſcles unrelaxed, and ſtill capable of diſturbing the fracture. Hence, we are decidedly of opinion, that, eſtimating the good effects of any poſition as highly as poſſible, we ſhall always be under the neceſſity of allowing, that poſition alone will not do what Pott has repreſented, and it will never diſarm and incapacitate the muſcles ſo effectually, as to leave none capable of ſeparating the ends of the fracture.

The preceding remarks tend to the concluſion, that, without neglecting whatever benefits may be derived from poſition, we ſhould endeavour to increaſe the power of ſuch mechanical contrivances as are intended to reſiſt the action of the muſcles on a broken thigh, and are calculated to keep the ends of the fracture in a ſteady ſtate of coaptation.

We ſhall now deſcribe the manner in which Mr. Pott recommended a broken thigh to be ſet and treated. We may premiſe, that he was in the habit of making the extenſion from the lower portion of the fractured bone, in order to accompliſh the reduction. He ſtates, that the poſition of the fractured os femoris ſhould be on its outſide, reſting on the great trochanter; the patient's whole body ſhould be inclined to the ſame ſide; the knee ſhould be in a middle ſtate between perfect flexion and extenſion, or half-bent; the leg and foot, lying on their outſide, ſhould alſo be well ſupported by ſmooth pillows, and ſhould be rather higher in their level than the thigh. One very broad ſplint of deal, hollowed out, and well covered with wool, rag, or tow, ſhould be placed under the thigh, from above the trochanter, quite below the knee, and another ſomewhat ſhorter ſhould extend from the groin below the knee on the inſide, or rather in this poſture, on the upper ſide; the bandage ſhould be of the eighteen-tail kind, and when the bone has been ſet, and the thigh well placed on the pillow, it ſhould not, without neceſſity, be ever moved from it again, until the fracture is united.

Two ſplints are only enumerated by Mr. Pott. The generality of practitioners now invariably employ four. After placing the patient in the moſt eligible poſition, the neceſſary extenſion is to be made. Then the under ſplint, having upon it a broad, ſoft pad, and an eighteen-tailed bandage, is to be laid under the thigh, from the great trochanter to the outer condyle. The ſurgeon, before applying the ſoap-plaſter, and the reſt of the ſplints, muſt take care to make the fracture lie as ſmoothly as circumſtances will allow.

We find that Mr. Pott adviſes the leg and foot to be raiſed ſomewhat more than the thigh. The propriety of this advice, however, is not very intelligible. Indeed, we are decidedly of opinion, that the method is wrong, for the following reaſons. What is the kind of deformity moſt to be apprehended after a fracture of the thigh; is it not a ſhortening of the limb, accompanied with a diſtortion of the foot outward? What is the effect of raiſing the leg and foot more than the broken os femoris? Is it not to twiſt the condyles of the bone in the external direction? And muſt it not therefore be improper, becauſe tending to promote a diſtortion of the lower part of the limb outward, the very kind of deformity which ſo often lames the patient, and throws diſgrace on the art of ſurgery?

Were we to mention one particular circumſtance which is more diſadvantageous than any other, in the bent poſture, we ſhould feel inclined to ſay, it was the unconfined, or rather the moveable condition in which ſurgeons are accuſtomed to leave the leg and foot. Some contrivance ought undoubtedly to be made, with a view of fixing theſe parts in an unobjectionable poſture. Whenever they move, they diſturb the coaptation, and whenever they get out of a particular poſition, they diſtort the limb.

Some practitioners have propoſed to place fractured thighs in a bent poſition, with the patient lying upon his back. The limb is to be laid on two boards, which meet and form ſuch an angle at the back of the knee-joint as will make the thigh and leg bend in the deſired way. The boards are to have two cuſhions placed along them, and the limb is to be prevented from ſlipping to either ſide, by wooden pegs for the purpoſe. Two ſplints are now to be applied to the thigh; perhaps a third one above might alſo be proper. Mr. Charles Bell has given an account of this method in his Operative Surgery, vol. 2, and we think that the propoſal has ſufficient merit to entitle it to a fair trial in practice. We think that we remember having ſeen, ſome years ago, an apparatus which was uſed at St. Bartholomew's hoſpital, and which could be employed in any poſition of the limb, in caſes of both fractured legs and thighs.

We have next to treat of the ſtraight or extended poſition, which was that to which Deſault gave the preference, and to which recourſe is univerſally had on the continent. This plan of treatment alſo cannot be regarded as totally abandoned

abandoned in this country, there being ſome ſurgeons of eminence who ſtill put it in practice.

The reaſons aſſigned by Deſault againſt the bent poſture are the following: the difficulty of making the extenſion and counter-extenſion when the limb is ſo placed; the neceſſity of then applying them to the fractured bone itſelf, inſtead of ſome part at a diſtance from the fracture, as for example the lower part of the leg; the impoſſibility of comparing with preciſion the broken thigh with the ſound one, in order to judge of the regularity of its ſhape; the irkſomeneſs of the bent poſition when long continued; the painful preſſure made on the great trochanter; the diſturbance of the limb, whenever the patient has a motion; the difficulty of fixing the leg ſo ſteadily as to prevent it from moving and diſplacing the fracture of the thigh; the utter impoſſibility of adopting ſuch poſture, when both thighs are fractured; finally, the plan having been attended abroad with little ſucceſs.

Deſault alſo conſiders, that what is gained by the relaxation of ſome muſcles in the bent poſition, is loſt by the tenſion of others.

Perhaps, out of the preceding reaſons, only a few could be ſelected, as carrying any material degree of validity. Theſe appear to us to be the following; the irkſomeneſs of the bent poſture in which the patient is obliged to lie, for a long while, on his ſide; the painful preſſure on the trochanter major; the moveable ſtate of the leg; the ill ſucceſs of the trials in France; the actually tenſe ſtate of certain muſcles, in a poſition which has often been called the *relaxed* one.

Deſault uſed to prefer applying the extending power to the foot, in order to have the advantage of a long lever, and to avoid preſſing and irritating the muſcles of the thigh, ſo as to make them reſiſt the reduction of the fracture with increaſed violence. This mode of making the extenſion, it is obvious, cannot be followed in the bent poſture, in which the thigh and leg are not placed in the ſame direction. However, the common reaſon aſſigned againſt making the extenſion on this principle is, that ſome of the force employed is loſt on the intervening joint, which may likewiſe be injured by the violence. With reſpect to any of the force being loſt, we could never diſcern how ſuch a circumſtance can happen; and the ample experience of Deſault has proved, that the other apprehenſion is deſtitute of foundation.

Deſault took care to put his patients with broken thighs on firm mattreſſes, which would not give way to the weight of the body, and allow a change of poſture to take place. This method is highly deſerving of imitation in all our public hoſpitals, whether the bent or the extended poſition be adopted.

Deſault maintains, that as the object of every apparatus for a fractured thigh ſhould be to keep the ends of the fracture from being diſplaced, every mechanical contrivance employed, ought to be calculated for reſiſting the cauſes producing the diſplacement. Theſe are, firſt, the action of ſuch muſcles as draw upward the lower end of the fracture; ſecondly, the weight of the trunk propelling downward the upper end. The preceding ſtatement naturally leads to the concluſion, that every apparatus for an oblique fracture of the thigh ſhould draw and keep downward the lower end of the fracture, and, at the ſame time, carry and keep upward the upper end of the fracture, and the trunk which is above it.

It is alſo explained by Deſault, that the apparatus ſhould be capable of reſiſting the rotation of the lower portion of the broken bone, which ought to be quite firm and ſteady, even in caſe the limb ſhould be ſuddenly moved.

The only few caſes in which, according to Deſault, the power of the apparatus to keep upward the pelvis and ſuperior end of the fracture, and to keep downward the inferior end, can be diſpenſed with, is, when the fracture is tranſverſe, and not at all diſplaced in the longitudinal direction of the bone.

The ſame diſtinguiſhed ſurgeon enters into a conſideration of the effect of the different pieces of the apparatus for fractured thighs, and he endeavours to ſhew, that little dependence can be put in any of the means, unleſs they are calculated to make permanent extenſion.

Bandages have all one common mode of operating; they preſs the muſcles towards the ends of the broken bone, and make them form a ſort of natural caſe for the fracture. In ſhort, bandages make a kind of lateral reſiſtance to the parts. Upon this principle, they are of material ſervice in preventing any diſplacement of the fracture ſideways, and they are moſt uſeful when the ſolution of continuity is tranſverſe. But, Deſault enquires, what is there to hinder the two inclined ſurfaces of an oblique fracture from ſlipping one over the other? What power is there to hinder the limb from receiving the effects of accidental ſhocks? Is the pelvis kept back? Is the action of the muſcles reſiſted? Deſault, indeed, admits, that the laſt object is ſomewhat fulfilled by the preſſure, and that in this operation the chief utility of the bandage conſiſts; but, he aſks, whether ſuch compreſſion will be adequate to prevent the longitudinal diſplacement of the bone, particularly when the bandage is ſlackly put on, as ſome practitioners recommend?

Theſe remarks apply alſo to compreſſes; "petit moyen contre une grande cauſe."

Splints are uſeful in firmly fixing the limb, and guarding it from the effects of accidental ſhocks, or of contractions of the muſcles. They operate more powerfully than bandages in preventing lateral derangement, and, hence, they ſuffice for tranſverſe fractures, without any permanent extenſion being employed. They can alſo reſiſt the rotation of the thigh outward, or inward. But, when the breach of continuity is oblique, will they hinder the ends of the bone from gliding over each other, and the conſequent ſhortening of the limb? They obviouſly could only do ſo, by the friction of the different pieces of the apparatus, eſpecially the tapes, which faſten it; and then, to make the reſiſtance effectual, they muſt be tied ſo tightly as to create a danger of mortification. Will the ſplints prevent the trunk from deſcending, and propelling before it the upper end of the fracture? Will they paralize the action of the muſcles on the lower end? Will they, in ſhort, fulfil all the above indications? Their uſe is almoſt limited to preventing lateral derangement, and ſteadying the limb. Hence, they ſhould extend along the leg, as well as the thigh, which is diſturbed by the motions of the lower part of the limb.

The pads are chiefly uſeful in keeping the limb from being galled by the ſplints, and tend only trivially to keep the fracture from being diſplaced.

From the above account it appears, that the ordinary pieces of apparatus, which do not execute any permanent extenſion, may perhaps ſuffice for tranſverſe fractures, which are not common; but, that they are always ineffectual, when the diviſion is oblique, becauſe they do not fulfil the two-fold indication of drawing downward the lower end of the fracture, and keeping the other one upward.

Deſault aſcertained, that the object particularly to be

aimed at, was ſuch a diſpoſition as that the foot, leg, thigh, and pelvis, ſhould conſtitute but one whole; ſo that, though the different parts thereof ſhould be drawn in different directions, yet they ſhould ſtill, with reſpect to one another, preſerve the ſame mutual relation. He invented the following apparatus to anſwer theſe purpoſes.

A ſtrong ſplint, long enough to extend from the ridge of the os ilium to a certain length beyond the ſole of the foot, is a principal part of this apparatus: this ſplint ſhould be two inches and a quarter broad, and have each of its extremities pierced in ſhape of a mortiſe, and terminated by a ſemicircular niche. It is applied on the exterior ſide of the thigh, by means of two ſtrong linen bands, each being more than a yard long.

The middle part of one of theſe bands is to be applied to the inſide of the thigh, at its upper part; its ends are brought to the exterior ſide of the thigh, paſſed through the mortiſe, and knotted on the ſemicircular niche. Compreſſes are to be previouſly placed under the middle part of the band, in order to prevent any diſagreeable preſſure; as well as on the tuberoſity of the iſchium, which Deſault conſidered as the principal point of action of this band. The inferior part of the leg is, in the next place, covered with compreſſes, on which the middle part of the ſecond band is placed: the extremities of this band are croſſed on the inſtep and upper part of the foot, then on the ſole, after which they are conveyed outward, and one end paſſed through the mortiſe and knotted with the other on the niche, with ſuch a degree of force as to pull the inferior portion of the femur downward, and to puſh the ſplint upward, and, by this means, the pelvis and ſuperior fractured portion. On the internal ſide of the limb is placed a ſecond ſplint, which extends from the ſuperior part of the thigh to a certain diſtance beyond the foot. A third is placed on the anterior part, and extends from the abdomen to the knee. The ſuperior extremities of the anterior and exterior ſplints are fixed by means of a bandage paſſed round the pelvis. A band, the middle part of which is placed under the ſole of the foot, and the extremities croſſed on its ſuperior ſurface, and faſtened to the ſplints, prevents the motion of the foot, as do alſo the ſplints.

Before applying the apparatus, the whole limb is to be covered with compreſſes, wet with a ſolution of the acetite of lead. Over theſe, Scultetus's bandage is to be put, and a roller round the foot, all moiſtened in the ſame manner.

It ſhould be obſerved, that Scultetus's bandage was made on the ſame plan as the eighteen-tailed one. It conſiſted of an indeterminate number of diſtinct bands, three inches in width, and of a ſufficient length to paſs twice round the limb. It ſhould be applied from below upwards, in ſuch a manner, that two-thirds of the width of one fold may be covered by the ſucceeding one.

Fractures of the inferior Extremity of the Thigh, with Separation of the Condyles.

Some caſes of this deſcription are related in the Pariſian Chirurgical Journal. In one inſtance, the accident was produced by the kick of a horſe on the internal condyle of the left femur. The pain was ſo great, that the patient was obliged to ſit down on ſome ſtraw that happened to be near him. He reached home, leaping on his right foot; which exertion greatly increaſed the pain, in conſequence of the motion making the lower part of the thigh ſwing backward and forward.

The following were the ſymptoms which were noticed: The thigh was found bent, and conſiderably ſhortened; there was not much ſwelling about the knee, but ſome contuſion and ecchymoſis. The joint, when looked at tranſverſely, had a ſtretched appearance, and was more flattened from before backward than the oppoſite knee. The patella did not project ſo much as in its natural ſtate, and, when preſſed, ſunk between the condyles; and, on preſſing the condyles together, was raiſed. The condyles admitted of motion on each other, could be ſeparated or moved in every direction, and were accompanied with a crepitus.

Theſe circumſtances evidently proved that there was a longitudinal fracture of the condyles. The body of the femur was alſo fractured above, an oblique ſolution of continuity deſcending in an oblique direction from about five inches above the external to within two inches of the internal condyle.

The ſtrong action of the muſcles of the thigh had drawn upwards that portion of the femur which was connected with the external condyle, and the upper portion of the bone had deſcended. The pointed edge of the latter piece had made a wound in the integuments, an inch and a half in length, on the inſide of the thigh a little above the condyle.

The patient was put on a ſtraw-bed, with a hard mattreſs underneath. Deſault obſerves, that it was formerly the cuſtom in the Hôtel Dieu to uſe feather as well as ſtraw-beds; but, from the inconveniences ariſing from their heat, and their yielding unequally in caſes of fracture, their uſe is now diſcontinued, and hard mattreſſes ſubſtituted in their room. The dreſſings having been previouſly diſpoſed on the bed, the ſurgeon proceeded to examine the wound; and, after diſengaging a piece of ſplintered bone, he proceeded to reduce the fractures in the following manner.

The counter-extenſion was made by fixing the patient to the head of the bed by proper bandages; and, whilſt one aſſiſtant ſupported him under the axilla, a ſecond kept up an extenſion, by laying hold of the foot with one hand and the heel with the other, whilſt other aſſiſtants ſupported the pelvis and the ſuperior part of the limb, to prevent the parts being ſhaken. A little inconvenience was experienced from the contraction of the muſcles during the extenſion, and the bones were brought in a ſtate of appoſition without any difficulty.

The parts were maintained in their ſituation by two circular compreſſes, and by a bandage, ſimilar to that of Scultetus; and the inequalities of the limb filled up with coarſe linen. The whole was ſupported by two ſtrong ſplints unequal in their length and about three inches in width, and covered with *drap fanon*.

The dreſſings, as before obſerved, being diſpoſed on the bed, were placed on the limb; they were wet with the aq. veg. and applied in the following manner: whilſt the extenſion was kept up by aſſiſtants, the two circular compreſſes were made to croſs each other forwards, one on the knee and the other on the inferior part of the thigh. The bandage was then applied from the ſuperior part of the leg to the upper part of the thigh: the ſides were then filled up as before with ſoft linen. The ſplints were then applied, one on the inſide, and the other externally, in ſuch a manner that the preſſure ſhould be equal at all points. The edges of the *drap fanon* were then brought over the limb, and properly ſecured by means of tapes; care was taken to tighten them ſufficiently near the fractured parts, and to tie the knots on the outſide of the ſplints, to prevent the inconvenience of preſſure. The ſplints deſcended ſufficiently low to be on a level with the ſole of the foot, but the outſide

ſplint

ſplint was conſiderably longer, and reached as high as the criſta of the ilium, whilſt the internal one extended only to the ſuperior part of the thigh. The upper end of the outſide ſplint was tied with a napkin round the pelvis, and properly ſecured by pins. In this manner the fragments of the bone were retained; but, in a fracture ſo complicated and oblique, little hope was entertained that it could poſſibly reſiſt the effect of muſcular contraction.

In the Hôtel Dieu, means have been ſucceſsfully employed to counteract the effect of the contraction of muſcles in caſes of fracture. Deſault here ſpeaks of permanent extenſion; a method reprobated by the generality of practitioners, as ſubject to inconveniences, which Deſault remarks he has never obſerved in the very conſiderable number of patients ſubmitted to the trial.

The patient was already ſo fixed to the head of the bed, by proper bandages round the body and under the axilla, that the trunk could not deſcend. The indication then left was to prevent the thigh bending on the pelvis; which was eaſily effected, by placing thick compreſſes behind the thigh, and paſſing, above the malleoli, the middle of a bandage, the ends of which were croſſed on the back of the foot, then tied at the ſole, and fixed to the foot-board of the bed.

This extenſion, ſo far from producing inconvenience to the patient, afforded him inſtant eaſe. He was fatigued from the jolting he experienced in his way to the hoſpital, but was free from fever: no medicine but a diluting ptiſan was ordered, and he was left to enjoy his reſt, which he ſtood much in need of. The next day, his ſymptoms, in every particular, were remarkably mild; it was only neceſſary to regulate his diet, and to keep the parts moiſt with the aq. veg. The day after, the ſame plan was obſerved; but, on the fourth day, the looſeneſs of the bandage, from the diminution of the ſwelling, rendered its re-application neceſſary. Suppuration began to take place in the wound: it was dreſſed in the ſame way as on the firſt day, and the dreſſings were re-applied with the ſame precautions.

The wound was dreſſed every two days till the ſixteenth, when it was cicatrized. Afterwards, the dreſſings were not renewed but when they were looſe. The parts were kept conſtantly moiſt with the aq. veg. and care was taken that the bandages, which procured the extenſion, were kept always tight.

The bandages, &c. were not totally left off till the ſeventy-fifth day, though the callus was ſufficiently firm ſome time before that period: all the fragments were united without deformity, and the thigh, within a few lines, was as long as the one on the oppoſite ſide; but the ſoft parts, round the articulation, were conſiderably thickened, and the patella ſeemed to form one piece with the femur.

Notwithſtanding this, the motion of the limb was ſoon reſtored, by bending and extending alternately the leg or the thigh, by means of a cuſhion, which, one day, was placed under the ham, and, the next day, under the leg; and by moving the patella, by means of the fingers, in every poſſible direction. The patient was ſoon capable of exerciſing it himſelf, and was able to walk with the aſſiſtance of crutches. The ſtiffneſs of the joint ſoon ſubſided, and, in three weeks, he was capable of bending, at a right angle, the leg on the thigh. He was diſcharged from the hoſpital at this time, with a certain aſſurance of ſoon recovering, by means of exerciſe, the perfect uſe of his joint. Pariſian Chirurgical Journal, vol. i.

Fractures of the Neck of the Thigh-bone.

Theſe caſes are generally conſidered as the moſt troubleſome fractures to which the os femoris is liable. The high ſituation of the ſolution of continuity in the bone confers on a vaſt number of muſcles the power of drawing upward the thigh, the knee, the leg, and the foot. When the bone is broken about the middle, we know that ſome of the triceps, together with the rectus, biceps, ſemi-membranoſus, ſemi-tendinoſus, gracilis, and ſartorius, has the power of pulling up the lower portion of the bone towards the pelvis; but, when the neck of the os femoris is fractured, a multitude of other muſcles alſo acquire this power, as, for inſtance, the upper part of the triceps, the pectinalis, the pſoas magnus, iliacus internus, and many others inſerted into the great trochanter.

A fracture of the neck of the thigh-bone is generally occaſioned by a fall on the great trochanter; but the accident may ariſe from a fall either on the knee or ſole of the foot.

The ſolution of continuity may happen either at the middle of the neck, where the neck joins the head of the bone, or, laſtly, where the neck unites with the great trochanter. In the laſt caſe, the fracture is ſituated on the outſide of the orbicular ligament of the joint.

The trochanter major itſelf is ſometimes broken off, at the ſame time that the neck of the bone is fractured.

In the majority of inſtances, the ſolution of continuity is ſaid to be tranſverſe, with reſpect to the direction of the neck of the bone. It was aſcertained by Deſault, that, in ſome caſes of this deſcription, the internal fragment is wedged in the external one; a circumſtance which is worthy of attention, becauſe it has been mentioned in explanation of the fact, which has often been noticed, of perſons walking home, after having broke the neck of the os femoris. Perhaps, this ability might, alſo, in ſome examples, be imputed to the circumſtance of the orbicular or capſular ligament of the joint remaining entire and unlacerated, while the ſolution of continuity is within it; for, it is plain, that, in this ſtate, the main portion of the thigh-bone cannot be diſplaced far upward.

The diagnoſis of fractures of the neck of the os femoris is not always eaſy. Sometimes the beſt and moſt experienced ſurgeons cannot extricate themſelves from doubt and uncertainty.

The patient always complains of acute pain on the ſlighteſt motion of the limb, and in general he becomes ſuddenly incapable of walking. The limb is ſhortened, but this change takes place in very different degrees in different examples. When the fracture occurs on the outſide of the capſular ligament; or when the fracture is on the inſide of the joint, but the ligament is lacerated; the main portion of the os femoris is likely to be drawn up to a conſiderable extent by the action of the muſcles, and, of courſe, the limb will be ſhortened in a remarkable manner. When the fracture is within the capſular ligament, and this ligament is entire, the aſcent of the thigh-bone will be materially limited and circumſcribed; and the degree of ſhortening of the limb, not being great, can only be found out by a careful compariſon of one limb with the other. Finally, when the ſolution of continuity in the neck of the bone is tranſverſe, and one fragment is locked in the other, there can be no ſhortening of the limb at all, and the patient may even be capable of walking.

The hurt limb may in general be rendered as long as the other by a moderate degree of extenſion; but, no ſooner does the ſurgeon leave off pulling, than the muſcles immediately draw the thigh upward, and ſhorten the limb again.

A ſwelling makes its appearance at the upper and front part of the thigh, proportioned in ſize to the extent to which the member is ſhortened.

When

When the limb is ſhortened, the trochanter major does not project as in the natural ſtate, but is drawn upward and backward toward the criſta of the ilium.

Deſault particularly noticed, that if the ſurgeon puts his hand on the great trochanter, and makes the limb rotate on its axis, this remarkable bony proceſs will be felt revolving on its own axis, as on a pivot, inſtead of deſcribing, as in the natural ſtate, the ſegment of a circle, of which the neck of the bone is the radius. The obſcurity attending this mode of forming a judgment will be in proportion to the nearneſs of the fracture to the head of the bone.

In almoſt all inſtances, the toes are turned outward by the action of the muſcles. Paré, Petit, and Deſault, however, have met with caſes, in which the foot has been turned inward. Perhaps, it may ſometimes happen that the weight of the limb will determine this poſition of the foot, particularly when the patient is old, debilitated, or in a faint condition.

An erroneous and pernicious doctrine has been maintained by ſome eminent men, among whom are profeſſor Ludwig, M. Sabatier, and M. Louis, that fractures of the neck of the thigh-bone cannot be cured without lameneſs and deformity. Theſe evils have been imputed to the deſtruction of the neck of the bone; a circumſtance which was thought to be unavoidable. The truth is, that lameneſs does not neceſſarily follow a fracture of the neck of the os femoris, as may be fully aſcertained by referring to the ſurgical writings of Boyer, Deſault, and Richerand. However, every man of experience will allow, that, probably in ſome very old ſubjects, no union ever takes place, and the lameneſs and deformity muſt then be irremediable.

The French ſurgeons treat fractures of the neck of the os femoris on the principle of permanent extenſion. Boyer executes this purpoſe by means of a machine with a ſcrew. Deſault, we know, was in the habit of making the permanent extenſion by means of a bandage applied to the foot. It becomes unneceſſary, however, to explain here the plan of treatment in the ſtraight poſition, as we have already ſaid enough of Deſault's apparatus in a preceding column, as well as of the principles which influenced his practice. We acknowledge the accuracy of moſt of his remarks on fractures; and we cannot refrain from expreſſing a hope, that we ſhall live to ſee ſome of his plans more extenſively tried by Engliſh practitioners.

In this country, fractures of the neck of the thigh-bone are generally treated in the bent poſition; though there are ſome ſurgeons, who put the limb in the ſtraight poſture with common ſplints.

Fractures of the Patella, Rotula, or Knee-pan.

The patella may be broken by external violence, or by a very powerful contraction of the extenſor muſcles of the leg, which are inſerted into it.

Authors ſpeak of tranſverſe, oblique, and longitudinal fractures; but, although the two firſt caſes are univerſally acknowledged, few writers admit the poſſibility of the laſt, unleſs as a conſequence of gun-ſhot wounds.

It has been remarked by M. Hevin, that a tranſverſe fracture of the patella is moſt frequently occaſioned by outward violence, while the leg is more or leſs in a ſtate of flexion; at which period, that bone is ſituated on the articular ſurface of the thigh-bone, with its two extremities firmly fixed.

The ſame kind of fracture is alſo found to be very often produced by the violent action of the extenſor muſcles of the leg, without any blow or fall upon the knee whatſoever. It is ſaid that theatrical dancers are particularly ſubject to the accident, on account of the ſtrong exertions which they are under the neceſſity of making in their various forced attitudes. Ruyſch mentions a caſe, in his Obſerv. Anat. Chir. in which the knee-pan was broken by the powerful contraction of the muſcles. He ſays, "Viſitavi cum magiſtro Petri Adriani filio, virum ſatis robuſtum, qui e ponte deſcendens, in terram ferè ceciderat; imò pede lubrico, reſiſtens tamen quantum potuit, in terram non fecerit prolapſus; ſed ab illâ reſiſtentiâ tranſverſim fracta eſt ejus patella, adeò quidem evidenter ut inter utramque partem locari potuerit manus, una enim ſuprà, altera infrà genu ſentiebatur." J. L. Petit alſo met with many fractures of the patella, which were cauſed by ſlips and efforts, without any direct application of external violence to the knee. The bone may even be broken in this way into ſeveral pieces.

It frequently happens that patients ſuppoſe the injury of the patella to ariſe from the fall, whether this is the fact or not, as they generally tumble down at the time of the accident; and the ſurgeon, without proper inquiry, would not be led to think that the accident is ſo often the mere effect of the contraction of the muſcles as it really is. The celebrated Camper firſt obſerved the fact, that very often the fall is the conſequence of the fracture, and not the fracture of the fall. By ſome cauſe or another, the line of gravity of the body is thrown backward; the muſcles in front exert themſelves to bring it forward again; the extenſors act on the patella; this breaks, and the fall follows.

Modern ſurgeons are ſo well appriſed of the circumſtance of the patella being very commonly fractured in the foregoing manner, that we are almoſt afraid of being deemed prolix for confirming the account by further facts. However, there are two inſtances, in Deſault's Œuvres Chirurgicales, deſerving inſertion on account of their being particularly ſtriking and convincing. One is the caſe of a ſoldier, who broke his patella in aiming a kick at a ſerjeant, whom, however, he miſſed. The other example is exceedingly curious: a man, on whom lithotomy had been performed, was ſeized, while in the operating theatre of the Hôtel Dieu, with moſt violent ſpaſms of his muſcles; and the extenſors of his legs, among others, acted with ſuch power, that, in the preſence of the ſpectators, they broke both the knee-pans.

In the caſes under conſideration, the pieces of the fractured bone are always more or leſs ſeparated from each other. This ſeparation is occaſioned by the contraction of the extenſor muſcles of the leg, the ſtrong tendon of which is implanted into the upper part of the patella, and even covers all the fore part of this bone in the form of an aponeuroſis. Sometimes the ſeparation is to the extent of four inches: in other examples, the interſpace is hardly perceptible, in conſequence of the patient having remained perfectly quiet from the moment of the accident, and the tendinous expanſion, which covers the patella and connects the fragments, being ſtill in an entire ſtate. Surgical writers adviſe us, in this circumſtance, to be careful not to rupture the aponeuroſis in queſtion, in examining the limb.

It ought to be underſtood, that the interſpace between the two portions of a fractured patella is not produced by a mutual and equal aſcent and deſcent of the upper and lower fragment. The upper piece may be drawn a conſiderable way upward by the action of the rectus, cruræus, and vaſti muſcles; but the lower one is capable of being acted upon by no muſcle, and can only be moved from the other by the flexion of the leg. It is on this account that the ſeparation is leaſt when the limb is extended, the upper fragment being then the only one which can be diſplaced. When the knee is bent, however, the lower fragment moves downward, at the ſame

time that the upper one is drawn upward, and, conſequently, the ſeparation muſt in this ſtate be the moſt extenſive.

Beſides the ſeparation of the two pieces of a fractured patella, there are other ſymptoms pointing out the nature of the accident. When the limb is extended, the upper fragment may be puſhed down into contact with the lower one, and a crepitus be felt on making them touch each other. The caſe is alſo attended with an inability to walk, acute pain, and a quick ſwelling of the joint.

Inſtances have occurred, in which the tendon of the extenſor muſcles has been ruptured juſt above the patella; but a more common accident is the rupture of the ligament of the patella itſelf, below this bone.

The prognoſis, generally delivered by the ancients, in regard to fractures of the patella, was very unfavourable. Ambroiſe Paré remarked that no perſon could recover from an accident of this kind, without a degree of lameneſs. Fabricius Hildanus, in ſpeaking of a man, forty years of age, who fractured the knee-pan, obſerves, "Ab initio, et ſi ex arte curatus fuiſſet æger, nihilominùs tamen dolores acutiſſimi aliaque ſymptomata ſupervenerunt. Tandem dolore reliquisque ſedatis ſymptomatibus, convaluit quidem, ſed claudicatio ac ſumma imbecilitas totius cruris ſecuta eſt, ità ut non niſi maximâ cum difficultate ambulare, et tibiam aſcendendo ſublevare poſſit."

Is it true, that the weakneſs and lameneſs of the limb proceed, as Paré deſcribes, from the callus preventing the knee from bending, and from the difficulty which the patient experiences in getting up riſing ſurfaces? Fabricius Hildanus, who deemed the foregoing opinion admiſſible, ventures, however, to expreſs a degree of doubt concerning it. "An fractâ patellâ," ſays he, "extuberantia calli talis eſſe poſſit, ut cavitatem hancce, quæ inter femur et os tibiæ magna eſt, adeò impleat ut motum actionemque genu impedire poſſit? Videmus enim, ut plurimum in reliquis oſſium fracturis, niſi contuſio oſſis et perioſtei fuerit maxima, naturam tam decenter et eleganter connectere oſſa, ut rarò relinquatur fracturæ veſtigium."

As an author in the Encyclopédie Méthodique remarks, if Fabricius Hildanus had only paid attention to the improper proceedings, followed at that time in the treatment of a broken patella, he would ſoon have diſcovered the true cauſe of the lameneſs, which was formerly a frequent conſequence of the accident. As the fragments of the bone were not put into contact, a large cartilaginous maſs was formed between them, which, not having the firmneſs of bone, permitted the two fragments to move ſeparately for the reſt of the patient's life; a circumſtance which could not fail to impair the motions of the joint. It ſhould alſo be obſerved, that ſometimes the upper fragment was drawn up almoſt as high as the point to which the extenſor muſcles could contract, ſo that, of courſe, the power of extending the leg was nearly deſtroyed.

It is true, that, in the old practice, the knee-joint was kept ſo long without motion, that an anchyloſis ſometimes enſued; but, now that practitioners adopt the plan of habituating the articulation to gentle motion, after a certain period has elapſed, this conſequence is hardly ever known.

Wander-Wiel, Ravaton, Pott, and ſome other writers, have maintained the doctrine, that a moderate interſpace between the two fragments of a broken patella was advantageous, and conducive to the perfect functions of the knee-joint after the cure. Certain it is, that, in the majority of caſes, the fragments are united by means of a ligamentous ſubſtance, inſtead of bone. But the opinion of the preceding authors ſeems to be by no means accurate. The patella is ſometimes repaired by callus, without any ill effects; and Default always found the joint more perfect, the ſmaller the interſpace between the fragments. When they were apart, he always found that the patient could not walk up riſing ſurfaces, or paſs over irregular ground, without conſiderable difficulty.

The indications, in the treatment of a fractured patella, are, firſt, to diminiſh the power of the rectus, cruræus, and vaſti muſcles, by adopting a poſition which will bring their origins and inſertions as near to each other as poſſible, and, alſo, by compreſſing the ſame muſcles with a roller applied over the thigh, from the groin to the knee.

Secondly, The lower fragment of the patella is to be put as near to the pelvis as poſſible, by extending the leg.

Thirdly, The upper fragment is to be puſhed down into contact with the lower one, and fixed in this poſition with a compreſs and a few turns of a roller.

Fourthly, The extended poſition of the limb is to be permanently maintained, by means of a long ſplint, placed either along the back or the outſide of the limb, and by laying the member on a ſurface which forms a gradual aſcent from the tuberoſity of the iſchium to the heel.

The practitioner is firſt to direct the patient to lie on his back, and enjoin him not to bend his knee in the leaſt. The leg is then to be perfectly extended, and the thigh ſomewhat bent on the pelvis. This poſture is then to be preſerved, by laying pillows under the heel, calf of the leg, and thigh. The patient's body and pelvis ſhould alſo be properly raiſed forward, ſo as to approximate the anterior inferior ſpinous proceſs of the ilium to the knee. The ſurgeon is now to apply a roller from the groin nearly down to the knee, obſerving to puſh downward the upper piece of the patella. When this has been brought into contact with the lower portion, it is to be prevented from aſcending again by laying juſt above it a little ſquare compreſs, which is to be fixed with a few turns of the roller.

Some writers have affected to think the application of a bandage to keep down the upper fragment quite uſeleſs, and even hurtful, by bringing on ſwelling, &c. However, experience has fully ſatisfied us of its utility; though we are perfectly convinced, that ſuch ſurgeons as apply another bandage, to keep up the lower fragment, adopt a very wrong and uſeleſs ſtep. For it muſt be allowed, that if the tight circles of a roller fulfil no ſurgical object, (and with reſpect to the lower fragment, which is quite fixed, they cannot,) they muſt be objectionable, on account of the manner in which they impede the freedom of the circulation in the limb.

A long ſplint, lined with a ſoft pad, is next to be applied all along the outſide of the limb; or one, ſomewhat ſhorter, may be put under the thigh and leg. This ſplint, which will ſecurely prevent all flexion of the knee, is to be fixed on with a roller.

It is a very good plan to lay the limb in a fracture box, in which a gradually aſcending ſurface is formed by pillows properly arranged.

When a broken patella is united by means of a long ligament, with the upper fragment of bone very much drawn up, the extenſor muſcles of the leg, not being able to pull the part much further upward, are deprived of a great deal of their original power. In this circumſtance Mr. Hunter uſed to adviſe the patient to ſit on a table, and exerciſe theſe muſcles, by alternately extending and bending the leg for a certain time every day. After this plan had been purſued for ſome while, Mr. Hunter recommended the patient to fix a weight on the foot. No doubt, in this way,

a patient

a patient may regain a good deal of the uſe of the weakened muſcles.

When the knee-pan is fractured by external violence, as by the kick of a horſe, it often happens that the upper fragment is not drawn upward and ſeparated, in conſequence of the parts not being ſufficiently ruptured and lacerated. In this inſtance, a bandage above the knee can anſwer no purpoſe, and, as being likely to have a bad effect on the inflammation of the joint, it ſhould not be employed. Here we muſt truſt to keeping the limb quietly extended. The chief indication is to avert the inflammation of the knee, by general and topical bleeding, the exhibition of mild ſaline purgative medicines, and the application of linen wet with the lotio aquæ lithargyri acetati to the joint itſelf.

Fractures of the Leg.

The leg is more frequently broken than the thigh; for, although it has the ſtrength of two bones, one of which is a very ſtrong one, it is greatly expoſed to external violence. When both the fibula and tibia are fractured, the patient is incapable of bearing his weight on the injured limb; but when the fibula alone is broken, progreſſion may ſtill be executed, though with difficulty and pain. When the tibia is the only bone which is fractured, the patient cannot uſe his leg; for notwithſtanding the fibula is entire, this bone is ſituated out of the centre of gravity, and is too weak to ſuſtain the weight of the body.

Fractures of both bones of the leg may be either tranſverſe or oblique.

When the fracture is diſplaced longitudinally, the lower fragments are generally drawn upwards and outwards, while the upper ones project inwards and forwards. An angular diſplacement may alſo proceed from the action of the muſcles on the back of the leg, or from the weight of the unſupported lower part of the broken limb. In either of theſe inſtances, the angle muſt be ſalient anteriorly. However, if the member be placed in the ſtraight poſition, and the heel be too much elevated, the angle may be ſalient in the direction backward. A ſpecies of diſplacement may alſo ariſe from an inclination of the foot too much inward or outward, the latter faulty poſition being that which is moſt commonly met with.

The longitudinal diſplacement can ſcarcely happen in tranſverſe fractures, becauſe the oppoſite bony ſurfaces reciprocally oppoſe the paſſage of one beyond the other. In oblique fractures, however, circumſtances are different, and the ſurfaces of the broken bones are incapable of preventing each other from gliding upwards and downwards. Hence it happens, that the lower portions of the broken bones, in caſes of oblique fractures, are generally drawn upwards by the muſcles of the calf of the leg, while the ſharp end of the upper piece of the tibia projects forwards, and may eaſily be felt under the ſkin.

Though ſuch is the common diſplacement of an oblique fracture of the leg, Boyer has explained that it is poſſible for a different appearance to preſent itſelf. It may occur, that when the ſolution of continuity runs obliquely downwards and outwards, the lower portions of the fractured bones may produce the projection forward, inſtead of the ſharp end of the upper piece of the broken tibia.

We may readily conceive how eaſy it muſt be for a ſimple fracture of the leg to be converted into a compound one, by the ſharp projecting point of bone making its way through the integuments. In fact, this circumſtance, which materially increaſes the degree of danger, is exceedingly common.

A fracture of both bones of the leg is generally attended with the following ſymptoms; acute pain, which is exaſperated by every kind of motion of the limb; an alteration in the natural figure of the member, in which a kind of angle is formed by the foot and lower fragments being drawn backwards; an inability of walking, or ſtanding on the limb; motion in the fracture, and a plain and manifeſt crepitus on handling the parts.

When the leg is fractured high up, near the knee, the ſurfaces of the tibia are ſo broad, that ſometimes no diſplacement whatever can be diſcerned. But this advantage is more than counterbalanced by the danger of the knee-joint becoming inflamed, and affected with anchyloſis, in conſequence of the accident, and long confinement requiſite for the union of the fracture. In this caſe, particular care muſt be taken to move the knee very tenderly and gently three or four times a week, after the fracture has acquired a certain degree of firmneſs.

Fractures of the Tibia alone.

When the tibia is the only bone broken, the fracture receives a conſiderable degree of ſteadineſs and ſupport from the fibula, which remains perfect, and acts like a ſplint on the limb. Indeed, fractures of the tibia, near the ankle or knee, are ſometimes by no means eaſily detected, becauſe there is no diſplacement, and the manner in which the fibula ſupports the injured bone hinders the fractured ſurfaces from moving ſufficiently on each other to communicate a diſtinct ſenſation of a crepitus. In certain examples, alſo, the degree of pain which patients have ſuffered have not deterred them from making an imperfect uſe of the limb.

In examining a tibia ſuſpected to be fractured, the ſurgeon ſhould trace the anterior ſurface of the bone, commonly called the ſhin, and its ſpine, or anterior ſharp edge. This ſhould be done for the purpoſe of aſcertaining whether any preternatural projection or inequality exiſts; for as ſuch parts of the bone are very ſuperficial, being only covered with ſkin, the leaſt irregularity becomes perceptible to the ſurgeon's fingers. When this method does not diſcover a fracture, the practitioner may put his fingers on any ſuſpected joint, and then move the ankle joint with a little freedom, by which means a crepitus will often be detected.

When the tibia is fractured alone, the accident has generally been produced by ſome violence (ſuch as a blow or kick), which has operated directly on the broken part.

Fractures of the Fibula alone.

The fibula may be broken by a fall, or a blow on the outſide of the leg, in which caſe the bone always gives way at the part to which the force is immediately applied.

Every one, who has the leaſt knowledge of anatomy, knows very well that the fibula does not bear the weight of the body, and that it can never be broken by the impetus of the body on the leg, unleſs the tibia firſt gives way. It is known to every ſtudent that the fibula extends down the outſide of the ankle-joint, and ſuch information makes it manifeſt that the fibula can only be broken by a force directly applied to it, or by a twiſt of the foot. Operative Surgery, vol. ii. p. 206.

The latter kind of caſe was one, of which the celebrated Pott took particular notice, as, when care is not taken to relax the muſcles, conſiderable trouble and difficulty occur in the treatment. It was remarked by this diſtinguiſhed ſurgical author, that when the tibia is forced from its juſt and perpendicular poſition on the aſtragalus, probably the capſular ligament, but always thoſe ſtrong ligamentous fibres, which connect the lower end of the tibia with the aſtragalus and os calcis, muſt be lacerated. Such is the caſe when the fibula breaks

breaks within two or three inches of the malleolus externus; when the inferior end of the fracture falls inward toward the tibia; when the malleolus externus is turned ſomewhat outward and upward; and the tibia, having loſt its proper ſupport, is forced off the aſtragalus inwards. To this perfect fracture, and partial diſlocation, is ſometimes added a wound in the integuments, made by the bone at the inner ankle.

Mr. Pott has ably explained, that in this example the difficulty in reducing the caſe, and maintaining the reduction, and the diſtortion of the foot upward and outward, are cauſed by the action of ſuch muſcles as have tendons paſſing behind the tibia and fibula, under the os calcis, or attached to theſe bones. Mr. Pott thought that the preſent inſtance ſerved as a ſtriking illuſtration of the utility of relaxing the powerful muſcles. If the limb be laid on its outſide, with the knee moderately bent, the muſcles forming the calf of the leg, and thoſe which paſs behind the fibula and under the os calcis, are all put, according to Mr. Pott, into a ſtate of relaxation and non-reſiſtance; all the difficulty and trouble, in general, vaniſh immediately; the foot may eaſily be placed right, the joint reduced, and, by obſerving the ſame poſition, every thing will commonly ſucceed.

In whatever manner a fracture of the fibula is occaſioned, the fragments cannot be diſplaced in the longitudinal direction. Their ends are always forced into the interoſſeous ſpace towards the tibia.

A fracture of the lower portion of the fibula may always be diſcovered with moderate eaſe, on account of the ſuperficial ſituation of this part of the bone, and the facility of feeling both a crepitus and any irregularity. When the fracture is higher up, more attention is neceſſary, becauſe the bone is here covered with a larger quantity of fleſh.

Treatment of Fractures of the Leg.

As in caſes of broken thighs, there are here two different plans of treatment; in one, the ſtraight poſition of the limb being preferred; in the other, the bent poſture. However, as the advocates for the firſt method are not in this country numerous, and the ſame apparatus and ſplints are employed in both ways, it only ſeems neceſſary to explain the mode of ſetting a fractured leg, as commonly followed by the moſt eminent Engliſh ſurgeons. At the ſame time, we wiſh it to be underſtood, that in our opinion the ſtraight poſition may occaſionally be adopted with advantage, when particular reaſons exiſt. Large abſceſſes and ſores, ſloughs, &c. on the outſide of the leg or foot, might certainly render the ſtraight poſture moſt eligible, as removing a good deal of preſſure off the diſeaſed parts, and facilitating the renewal of the dreſſings.

The powerful muſcles of the calf of the leg are to be relaxed by bending the knee and extending the foot, and the limb is to be laid in this poſition on its outſide, with the foot properly ſupported. The ſurgeon is now, with his aſſiſtants, to make whatever extenſion and counter-extenſion may be requiſite for reducing the fracture into an even ſtate of coaptation.

We cannot uſe better ſplints than thoſe employed by Mr. Sharp; only it is adviſable to have them made of tin or wood, inſtead of paſteboard, which is not well calculated for withſtanding the effect of any moiſture, diſcharge, &c. with which theſe inſtruments muſt ſometimes come into contact. Mr. Sharp's ſplints are particularly good, as in one of them a proviſion is made for the more eaſy ſupport of the foot and ankle, and there is a prolongation of the lower, or fibular ſplint, for the purpoſe of keeping the foot ſteady.

The fracture having been reduced, the ſurgeon ſhould carefully raiſe the leg a little way from the ſurface of the bed, by taking firmly hold of the limb, below and above the fracture, and elevating the broken bones together, in ſuch a way as ſhall keep both the upper and lower portions, as nearly as poſſible, on the ſame level. At this moment, an aſſiſtant ſhould put exactly under the leg the under ſplint, which has been previouſly prepared, by covering it with a ſoft pad, and laying over this an eighteen-tailed bandage. The leg is now to be gently depreſſed, till it becomes ſupported on the apparatus. The ſurgeon, before he proceeds further, ſhould once more obſerve, that the ends of the bones are evenly in contact. Being aſſured of this important point, he is to apply a piece of ſoap plaſter over the ſituation of the fracture, and lay down the tails of the bandage. Another ſoft pad, well filled with tow, is next to be put over the upper ſurface of the leg, and the other ſplint applied. The ſtraps ſhould be tight enough to make the ſplints prevent any motion of the ends of the fracture. The preſſure of theſe hard inſtruments is often exceedingly painful, and even productive of ſloughing and ulceration, unleſs the ſurgeon ſkilfully place ſoft materials between them and ſuch parts as ſeem moſt liable to be injured in this manner; for inſtance, the lower end of the fibula; the outſide and inſide of the foot; the inſide of the knee, &c.

Beſides the two ſplints and pads already mentioned, when the fracture is oblique, and the heel has a great tendency to be drawn backward, this effect may be much counteracted by applying a compreſs and longitudinal piece of paſteboard, from the lower part of the belly of the gaſtrocnemius muſcle to the heel, under the ſtraps of the other ſplints. This method prevents deformity in a very powerful manner.

When there is a great deal of contuſion of the ſoft parts, together with the injury of the bones, it is better, at firſt, to keep the leg wet with the lotion of ſal ammoniac and vinegar, by means of linen dipped in this application, and put under the ſplints. The ſplints need not be taken off every time it is neceſſary to wet the linen again; it is quite ſufficient to ſqueeze the fluid out of a ſponge into the interſpaces between the above inſtruments. Nothing is ſo prejudicial, in caſes of fractured bones, as too frequently moving the injured parts.

Mr. Pott acknowledged, that, in the fracture of the fibula only, the poſition is not of much conſequence; becauſe, by the tibia remaining entire, the figure of the leg is preſerved, and extenſion quite unneceſſary. Still even here, he contended, that laying the leg on its ſide, inſtead of on the calf, is attended with one very good conſequence, *viz.* that the confinement of the knee, in a moderately bent poſition, does not render it ſo incapable of flexion and uſe afterwards, as the ſtraight, or extended poſition of it does, and, conſequently, that the patient will be much ſooner able to walk, whoſe leg has been kept in the former poſture, than he whoſe leg has been confined in the latter.

We have juſt to remark, that when the ſtraight poſture is adopted, it is beſt to lay the limb in, what is called, a fracture-box.

Fractures of the Foot, Toes, &c.

The os calcis is now and then fractured, and, in general, by the fall of ſome conſiderable weight upon it.

When the ſoft parts, and the reſt of the foot, are ſeriouſly bruiſed and cruſhed at the ſame time, it may be more proper to perform amputation at once, than try to ſave the limb. If the miſchief, added to the fracture of the os calcis, is leſs alarming, the gaſtrocnemius and ſoleus muſcles ſhould be kept relaxed by bending the knee, and maintaining the foot extended, with the aid of compreſſes and a ſplint applied over the inſtep and front of the leg. If the integu-

ments are wounded, proper care muſt be taken to dreſs the cut part, and change the dreſſings as often as neceſſary. A roller ſhould alſo be put over the foot and leg.

The other tarſal bones cannot be fractured, without the operation of ſuch violence, as muſt infallibly cruſh a great part of the foot to pieces. In moſt of theſe inſtances amputation will be indiſpenſable; but, no more of the foot ſhould be removed than abſolutely neceſſary, as the reſt will be of infinite ſervice to the patient. It muſt be confeſſed, however, that very often the miſchief done is ſo great, that the operation muſt be ſo done as to remove the whole of the foot. The practitioner may then either operate at the ankle-joint juſt above this ſituation, or in the uſual place, a little below the inſertion of the flexor tendons of the leg, as his judgment may direct.

When the metatarſal bones, or toes, are fractured, and the ſkin is unwounded, the foot may be put on a ſplint adapted to the ſole in ſhape; a piece of the emplaſtrum ſaponis applied; and then a common roller. It is almoſt needleſs to add, the patient muſt remain in bed until the ſolution of continuity in the bone is repaired.

Fracture, in *Mineralogy*. See Minerals.

FRADES, Dos, in *Geography*, a river of Braſil, which runs into the Atlantic, S. lat. 17°.

FRÆNUM, in *Anatomy*, a name given to ſuch parts as have the effect of confining the organs to which they belong. Thus there are the frænum of the tongue, and the fræna of the lips, ſee Deglutition; the frænum of the epiglottis, ſee Larynx; and the frænum of the prepuce, ſee Generation.

Frænum *Linguæ, Diviſion of*, an operation in *Surgery*, ſometimes neceſſary in order to enable infants to ſuck, and children to form the voice.

The membrane, which lines the mouth, forms underneath the tongue a kind of duplicature, by which this organ is connected with the neighbouring parts. The membranous fold, to which we have juſt now alluded, is ſometimes denominated by anatomiſts the anterior ligament of the tongue; but its common name is the frænum linguæ.

When this part extends further towards the point of the tongue, and particularly, when it is of a denſer ſtructure than ordinary, it may impede the free motion of the tongue in ſuch a manner, that the actions of ſucking, and of articulating words, will be prevented.

The method of removing this defect conſiſts of an operation which has the ſemblance of being exceedingly ſimple, ſince nothing more is requiſite, than to make a trifling cut in a part of very inconſiderable thickneſs. However, it is an undoubted truth, that, if ſuch inciſion be careleſsly performed, very bad and fatal conſequences may be induced. The ſubject, therefore, demands more attention than may be ſuppoſed.

The firſt circumſtance worthy of notice, is never to cut the frænum linguæ of new-born children, unleſs the operation be indiſpenſably neceſſary. A judgment of ſuch neceſſity cannot be formed from merely obſerving that the frænum is preternaturally diſpoſed, and that the child has ſome difficulty in getting hold of the nipple. The prejudices of ſuch perſons as have the care of children often make them find out errors of formation, which do not really exiſt; and every practitioner is frequently conſulted about infants, reputed to be tongue-tied, when there is nothing unnatural in the ſtructure and diſpoſition of the frænum linguæ.

It ſhould be well known by all ſurgeons, that there are ſeveral cauſes which may prevent a child from ſucking, without the frænum linguæ being at all concerned. When the nipple is ſo ſmall that the child cannot get it ſufficiently into its mouth, or on the contrary, when the nipple is ſo large that the infant cannot fix it in its mouth; ſome time muſt elapſe before the child can habituate itſelf to this ſtate of things. There are alſo ſome infants who put their tongues againſt the roof of the mouth, inſtead of embracing with them the lower part of the nipple. Children of this deſcription are quite unable to ſuck, notwithſtanding they poſſeſs all the requiſite conditions for the performance of ſuch function. Sabatier obſerves, that in this laſt kind of caſe, it has been found in ſome meaſure neceſſary to teach the child how to move its tongue, by preſſing this part downward and keeping it in ſuch poſition with a ſpatula, until the nipple has been put into the mouth and properly taken hold of.

An opinion may be formed, whether the infant is defective in any of the conditions requiſite for the performance of ſuction, by introducing a finger into the mouth. When the child can inſinuate its tongue under the finger, which then lies in a kind of concavity on the upper ſurface of that organ; and when the child is alſo capable of drawing its tongue back, ſo as to occaſion an empty ſpace in the forepart of the mouth, the ſurgeon may reſt aſſured, that, in the formation of the parts, there is no cauſe preventive of the action of ſucking. But when the infant is incapable of putting its tongue under the finger, and eſpecially when it is alſo unable to make a ſort of longitudinal groove on the dorſum of that organ, it becomes highly probable that the neceſſary degree of motion is prevented by the frænum, and that a diviſion of this latter part is indiſpenſable. There is no other admiſſible reaſon whatever for performing the operation; not even the apprehenſion, that the ſtate of the frænum may be a future impediment to the perfect production of the voice. For, ſhould this laſt fear be realized, the frænum may then be more ſafely divided than at an earlier period, becauſe the child will now have become more rational, more docile, and conſequently leſs apt to move about too much at the time, when the operator is engaged in making the neceſſary cut.

In ſome inſtances the frænum is found to extend too far forward, to the very point of the tongue, while, in other examples, it is obſerved not to be of ſufficient length to allow the tongue to be properly raiſed from the bottom of the mouth. The firſt kind of defect is ſaid to be that which is moſt commonly met with.

Every ſurgeon may readily inform himſelf by ocular inſpection, whether the frænum reaches along to the apex of the tongue; for, in the natural ſtate, it is well known that about a quarter of an inch of the under ſurface of the tongue, from the apex backward, is quite unconnected with the frænum. Alſo when this part, by reaſon of its ſhortneſs, ties the tongue too cloſely to the bottom of the mouth, the ſurgeon cannot raiſe the tongue to the palate with his own fingers.

The frænum linguæ is to be divided with a pair of very ſharp ſciſſars without points. The ſurgeon is to make the requiſite cut with his right hand, while the fingers of his left are employed in holding up the end of the tongue. The fingers having been found by ſome operators inconvenient on account of their thickneſs, which hinders the parts about to be divided from being well ſeen, ſome have uſed a kind of blunt fork for confining the tongue and rendering the frænum tenſe. Inſtead of ſuch an inſtrument, J. L. Petit was in the habit of employing the common director,

the handle of which was made flat, and with a fiſſure for the reception of the frænum.

Though we have mentioned theſe inſtruments, we have to remark, that modern ſurgeons univerſally prefer the uſe of the fingers of their left hand; and ſince we conſider every ſuperfluous increaſe in the number of ſurgical inſtruments as diſadvantageous to the real improvement of practice, we moſt heartily join in condemning both the blunt fork and Petit's inſtrument as totally unneceſſary.

Another method, undeſerving of recommendation, has alſo been put into practice. The ſciſſars, and one of the latter inſtruments, employed both the hands of the operator, who was obliged to get an aſſiſtant to ſupport the child's head. Now it was conceived, that the ſurgeon might be made to cut more than was required, and do miſchief, if the aſſiſtant failed in holding the head with a due degree of ſteadineſs. In order to avoid this exaggerated inconvenience, another inſtrument was invented, which was calculated for fulfilling all the indications at the ſame time. The inſtrument alluded to was a metallic ſheath, containing a biſtoury, and conſtructed with a fiſſure. The knife was retained by a mechanical contrivance on the right ſide of the fiſſure, in which the frænum was placed. On preſſing a ſort of ſtop, the blade became diſengaged, and moved with celerity acroſs the fiſſure, ſo as to cut the frænum. It was remarked by Petit, that the knife did not always do what was wiſhed, ſince the frænum ſometimes yielded, and was puſhed between the two plates of the metallic ſheath. Here it became entangled, and could not be got out without ſetting the ſpring again, a thing which the motion and crying of the child often rendered very difficult of accompliſhment. The accident depended on the very ſmall ſegment of a circle deſcribed by the knife, which, inſtead of being drawn along the part intended to be divided, as every cutting inſtrument ought to do, fell upon the frænum in a perpendicular manner. Hence Petit ſubſtituted ſciſſars for the biſtoury, and had one blade fixed on one ſide of the fiſſure, while the other blade was moveable, and kept ſeparated from its fellow by a little ſort of lock, which might eaſily be unfaſtened. On this being done, the laſt blade uſed to approach the one which was fixed, croſſing the fiſſure in which the frænum linguæ had been previouſly put.

In regard to any kind of concealed biſtoury, for the performance of the operation under conſideration, we have to ſtate that the ſurgeons of the preſent day invariably diſpenſe with all inſtruments, except a pair of very ſharp ſciſſars, without points.

Before the time of Petit, ſome bad conſequences, apt to be produced by the operation of dividing the frænum linguæ, had been little taken notice of by ſurgical authors. This eminent ſurgeon, however, had been impreſſed by experience with the knowledge of theſe dangers, and he wrote on the ſubject an intereſting paper, which is publiſhed among the Memoires de l'Academie des Sciences for the year 1742. One bad conſequence, to which we have made alluſion, is the ſuffocation of the child by the tongue turning backward. Another danger is an hemorrhage, which occaſionally follows the operation.

The frænum ſerves to confine the tongue, and keep it from being thrown too far backward in the action of deglutition. Now in the operation, if an unneceſſary, or too extenſive an inciſion be made, the tongue may be carried beyond the narrow part of the throat, and ſo engaged in the opening of the pharynx, as not to admit being brought back again into its natural ſituation. The firſt opportunity which Petit had of obſerving this event, was in a child that had died about five hours after its frænum linguæ had been divided, and whoſe body this diſtinguiſhed practitioner was requeſted to examine. Upon paſſing a finger into the child's mouth, he was ſurpriſed at not being able to feel the tongue, and at perceiving, that the poſterior opening of the mouth was completely ſtopped up by a fleſhy ſubſtance. As ſoon as an inciſion had been made through the cheeks, it became evident, that this ſubſtance was the tongue itſelf which had been thrown into the upper part of the pharynx in the effort of ſwallowing.

When M. Petit was ſent for to another infant which had fallen into a ſtate approaching to ſuffocation, about two hours after its frænum linguæ had been cut, he endeavoured to find out the cauſe of the occurrence. When he introduced his finger into the child's mouth, he found that the tongue was half diſplaced backward. There was no difficulty in reducing it; but the accident recurred ſeveral times in the courſe of the day. Petit conceived, that it was now neceſſary to have recourſe to ſome mechanical means for the prevention of the part becoming diſplaced. This purpoſe ſeemed to be anſwered by a thick compreſs, which was placed on the tongue, and retained by a band applied round the lower jaw. Whenever the child had occaſion to ſuck, the apparatus was taken off, and put on again immediately afterwards. The little patient was ſent into the country with a ſtrict injunction, that the nurſe ſhould continue for ſome time the uſe of the compreſs and bandage. The direction however having been neglected, the child was ſeized with ſymptoms of ſuffocation and died.

After the caſe, which we have juſt now cited, M. Petit met with other examples, in which children, affected in a ſimilar way, were ſaved by a perſeverance in the plan above deſcribed.

The ſecond dangerous conſequence, occaſionally reſulting from the operation of dividing the frænum linguæ, is an hemorrhage which takes place when one of the raminal arteries, or veins, is wounded. This kind of accident has long been well known, and all writers who have treated of the operation of cutting the frænum have not failed to notice it. M. Petit however has ſeen the ſame perilous occurrence take place, even when the large veſſels of the tongue were uninjured, and, of courſe, the bleeding proceeded entirely from ſuch ſmall veſſels as are diſtributed to the membrane of the frænum itſelf. The blood, which eſcapes from theſe veſſels, and collects in the child's mouth, induces the infant to make continual endeavours to ſuck, by which means the bleeding is kept up, until the weakneſs occaſioned is extreme. Several examples of ſuch hemorrhages were met with by the above ſurgeon. Unavailing attempts were made to ſtop the flow of blood by aſtringent applications, and badly contrived compreſſes. M. Petit deviſed a ſimple and effectual means of ſtopping the bleeding. The method conſiſts in taking a piece of birch, which is to be cut through below the place where two branches of equal ſize unite. The bit of birch is to reſemble a ſort of fork, the prongs of which are to be about eight lines long, and the handle four. The inſtrument is then to be covered all over with linen, and put under the tongue, in ſuch a way, that the end of the handle is to reſt againſt the middle of the concavity of the arch of the jaw, while the prongs embrace the frænum, and compreſs the bleeding veſſels. The middle of a roller is next to be applied to the dorſum of the tongue, as far back as poſſible, and the ends, after croſſing each other under the chin, are to be pinned to the child's night cap. In this manner, the veſſels are compreſſed from below upward by the prongs of the wooden fork, while the bandage makes preſſure from above downward. Thus the tongue is fixed, and the bleeding is ſtopped. De la Médecine Opératoire, par Sabatier, tom. 3.

FRAGA, in *Geography*, a town of Spain, in Aragon, on the frontries of Catalonia. This is the ancient town of the Ilergetes, called by Ptolemy Gallica Flavia, and was of conſiderable importance under the Moors, and under the kings of Aragon. It had a diſtinct king under the former; but it is now reduced to a population of about 3000 perſons. It is ſituated on the left bank, or eaſt and north of the river Cinca, which bathes its walls, between two mountains, on the ſides of which it is built. The ſtreets are narrow, crooked, hilly, and badly paved with ſharp pebbles. The houſes are badly conſtructed, and appear like huts or ruins, though many of them are decorated with armorial bearings. This town is in the dioceſe of Lerida, belonging to Catalonia, and is the reſidence of a vicar of the biſhop. It has two alcades, eight regidors, three gates, a convent of Grand Auguſtins, and two pariſh churches. A handſome quay has been lately built upon the bank of the river Cinca. This place was formerly a fortified town, and defended by a caſtle, now in ruins. It ſuſtained ſeveral ſieges under the Moors, and reſiſted the armies of Aragon in 1133 and 1134; and Alphonſo I. king of Aragon, was ſlain under its walls. Fraga was at laſt taken in 1147 by Raymond Berenger, count of Barcelona, who had aſcended the throne of Aragon, in conſequence of his marriage with Petronilla, the daughter and heireſs of king Ramirez. At the commencement of the 18th century, in 1705, it was taken by the troops of the archduke Charles, but ſhortly afterwards retaken, and ſubjected to Philip V. The Catalonian language is ſpoken at Fraga, and the manners of its inhabitants reſemble thoſe of the Catalonians. The quay leads to a handſome wooden bridge, of 22 arches, over the river Cinca; and near it is a convent of capuchins, having an immenſe incloſure, with a large and beautiful garden. It is diſtant 53 miles E.S.E. of Saragoſſa. N. lat. 41° 27'. E. long. 0° 17'.

FRAGARIA, in *Botany*, ſo called by the Romans, from *fragro*, to ſmell ſweet or powerfully, on account of the perfume of its fruit.—Strawberry.—Linn. Gen. 255. Schreb. 342. Willd. Sp. Pl. v. 2. 1090. Lamarck. Dict. v. 2. 527. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 546. Juſſ. 338. Tourn. t. 152. Gærtn. t. 73. Claſs and Order, *Icoſandria Polygynia*. Nat. Ord. *Senticoſæ*, Linn. *Roſaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, flat, in ten ſegments; the five alternate ones external and narroweſt. *Cor.* Petals five, roundiſh, equal, ſpreading, inſerted by their ſhort claws into the calyx. *Stam.* Filaments 20, awl-ſhaped, ſhorter than the petals, inſerted into the calyx; anthers creſcent-ſhaped. *Piſt.* Germens numerous, very ſmall, collected into a head; ſtyles ſimple, inſerted laterally into each germen; ſtigmas ſimple. *Peric.* none. A ſpurious berry is formed of the common receptacle of the ſeeds enlarged and become pulpy, ſoft, coloured, of a roundiſh ovate figure, abrupt at the baſe, deciduous. *Seeds* numerous, minute, pointed, ſmooth, naked, ſcattered over the ſurface of the receptacle.

Eſſ. Ch. Calyx inferior, in ten ſegments. Petals five. Receptacle of the ſeeds ovate, pulpy, deciduous. Seeds ſmooth.

Linnæus, diſguſted with the futile diſtinctions of the gardeners of his time, eſpecially in Holland, ſometimes ran into a contrary extreme among plants the moſt generally cultivated; and conſidered as varieties what are really diſtinct ſpecies; differing in their native countries, their qualities, and even their botanical characters when inveſtigated according to his own ſoundeſt principles of diſtinction. This it appears to us he has done among the different kinds of ſtrawberry, reducing them all principally to one ſpecies. On this ſubject very great light has been thrown by the labours of Ducheſne, in his excellent *Hiſtoire Naturelle des Fraiſiers*, printed at Paris in 1766. This is a model of accurate and ingenious obſervation and criticiſm, and Haller juſtly terms it "an excellent little book." In it the author inveſtigates the characters and qualities of all the kinds of ſtrawberries known to him, traces their origin, their relationſhip to each other, and their ſynonyms in books, with the greateſt accuracy and clearneſs. The ſubject is followed up by the ſame writer in an eſſay communicated by himſelf, and ſigned with his name, in Lamarck's *Dictionaire de Botanique*, v. 2. 528. In theſe publications the only error perhaps is an hypothetical idea of the plants in queſtion being, ſomehow or other, all deſcended from a common ſtock; conſequently there is no attempt at a diſcovery of ſolid ſpecific differences; and this poſſibly confirmed Linnæus in his original error reſpecting them, though he was furniſhed by Ducheſne with excellent ſpecimens of all the kinds, which ſtill remain in his herbarium, and which might well lead to a ſuſpicion at leaſt, if not a ready detection, of certain ſpecific diſtinctions. This error has been corrected, in the moſt maſterly manner, by Ehrhart in his *Beiträge*, faſc. 7, publiſhed at Hanover in 1792, who, by attending to the pubeſcence of the ſtalks and its direction, has determined the ſpecies beyond diſpute, corroborating the leading diſtinctions derived from habit, native country, &c. in Ducheſne's works; ſo that we preſume the ſpecies of *Fragaria* can hereafter never be obſcure, whatever new varieties may ariſe, or old ones diſappear. We do not indeed find ſome other characters, derived by Ehrhart from a compariſon of the terminal ſerrature of each leaflet with its next neighbours, ſo much to be depended on, but theſe are not wanted. The direction of the pubeſcence, ſo uſeful in Mints, ſee *Tranſactions of the Linnean Society*, v. 5. 171. and in *Myoſotis*, ſee *Engl. Bot.* t. 1973, and *Introd. to Bot.* 228, is all-ſufficient. Willdenow has very judiciouſly profited by the remarks of Ehrhart, only following Linnæus in erroneouſly conſidering the ſimple-leaved ſtrawberry as a ſpecies. We ſhall try to arrange and define the ſpecies of *Fragaria*, by the lights which theſe writers afford; only as we do not aſſent to Ducheſne's hypotheſis of their common origin, we ſhall diſpoſe them according to our own ideas of their botanical affinities. We ſhall endeavour to refer each variety, as far as we have ſeen any, or can judge by the accounts of Ducheſne, to its proper ſpecies. We cannot however undertake even to enumerate all the evaneſcent varieties of gardeners, whoſe intereſt it is to bewilder the ſubject by extolling the ſlighteſt novelties, or recommending old plants under a new name. This is too much practiſed, not by the intelligent leaders in the trade, but by ſuch as have no other means of exciting notice. If we ſhould ſeem to any perſons, ſkilled in the different merits and qualities of theſe fruits, too ſlight in our notice of ſome of their diſtinctions, we beg leave to remind them of the endleſs varieties of apples and pears, all produced by ſeed, and ſooner or later returning to their common origin. Even in the common crab, wild in our hedges, accurate enquirers may diſcover great differences in flavour and quality, which render the varieties of fruit in wild ſtrawberries, and ſtill more in cultivated ones, perfectly credible, and guard us againſt the erroneous multiplication of ſpecies.

1. F. *veſca*. Wood Strawberry. Linn. Sp. Pl. 708. Fl. Suec. 175. Engl. Bot. t. 1524. (Fragaria; Camer. Epit. 765. Brunf. Herb. v. 2. 35. F. ſylveſtris; Ducheſne 61. Lamarck Dict. n. 2. F. vulgaris; Ehrh. Beitr. n. 1.) Calyx of the fruit reflexed. Hairs of the leaf-ſtalks widely ſpreading; thoſe of the partial flower-ſtalks erect. Native of groves and thickets throughout the colder parts of Europe. Dr. Sibthorp found it in the woods of the Bithynian Olympus,

Olympus, and in ſome parts of Greece. In Sweden and Lapland it is ſtill more abundant than with us, ſo that it is ſcarcely neceſſary to keep Strawberries, except exotic kinds, in a garden. The *root* is fibrous, or rather woody, perennial, encreaſing by buds, as well as by long creeping ſhoots or runners. *Stem* none. *Leaves* ternate, on long hairy ſtalks, ſomewhat ovate, ſtrongly ſerrated. *Flower-ſtalks* longer than the leaves, erect, hairy, ſomewhat cymoſe. *Flowers* white, erect, ſpreading. *Fruit* drooping, ovate, fragrant, highly grateful and aromatic. Such likewiſe is the general habit of the genus; but this ſpecies, which is the ſmalleſt, is diſtinguiſhed by its acid fruit of a deep carmine red, and eſſentially by the ſilky hairs of its partial or ultimate flower-ſtalks being erect, or often cloſely preſſed upward to the ſtalk, which unfortunately is not properly repreſented in *Engliſh Botany*; but the excellent old wooden cuts above quoted, expreſs it by not ſhewing any hairs on that part, while the main flower-ſtalk, as well as the foot-ſtalks, of the leaves, are juſtly drawn rough with prominent or horizontal hairs. This character remains in the dried ſpecimens. Ehrhart has not diſtinguiſhed between the hairs of the general and partial flower-ſtalks. He and Willdenow ought, in all the caſes in queſtion, to have uſed the word *pedicellus*, not *pedunculus*. The Wood Strawberry flowers in May and June. By cultivation the leaves grow larger, but the fruit is little changed. The varieties are

a. With variegated leaves. Ducheſne 69.

b. With white fruit. Ducheſne 71. This writer remarks, that the points of the ſerratures of the leaves alſo are white, though in all red-fruited Strawberries they are red; a curious obſervation, which helps cultivators to diſtinguiſh this variety at all ſeaſons.

c. With a double flower. Ducheſne 74. In this the petals are very much multiplied, but ſo many ſtamens ſtill remain unchanged, that the fruit is generally perfected.

d. With cluſtered fruit, as deſcribed by E. Konig in the Ephem. Nat. Curioſ. for 1685. Ducheſne 79. This was unqueſtionably the mere accident of a faſciculate or cluſtered ſtalk, as happens in the ſtem of the Top-knot Pea, and occaſionally in the Aſh, Holly, Spurge-laurel, and ſeveral other plants. See FASCICULATE.

e. With prickly fruit. Ducheſne 82. Fragaria muricata; Linn. Sp. Pl. 709. Lam. Dict. n. 8. F. veſca *β*. Sm. Fl. Brit. 546. F. elatior *β*; Willd. Sp. Pl. v. 2. 1091. F. ſpinoſo fructu; Barrel. Ic. t. 90. F. arborea con fiore erbaceo; Zannon. Iſt. 95. t. 38. This was obſerved by Tradeſcant in a garden at Plymouth; ſee Gerard's Herbal by Johnſon, 998. Ducheſne ſaw an original ſpecimen of Zannoni's, who cultivated this plant at Bologna. The former reduces it, very ſatisfactorily, to the F. *veſca*, and aſſures us the prickly appearance of the fruit, which is not eatable, is owing to an elongation of the point of each germen. This variety, after having been kept in the botanical gardens of Europe, by way of a curioſity, for three or four ſcore years, has, according to Ducheſne, at length totally diſappeared, having no valuable quality to recommend it.

f. With abortive fruit. Ducheſne 107. Blind Strawberry. F. abortiva; Lam. Dict. n. 11. A ſtronger, more hairy, and darker-coloured variety than the common Wood Strawberry, in which reſpects it approaches the Hautboy hereafter deſcribed. The fruit is for the moſt part abortive, which Haller attributed to a defect in the ſtigmas, and Miller to an exhauſtion of the plant by runners; but Ducheſne now ſeems to doubt the accuracy of both theſe explanations, though without propoſing any in their ſtead. He conſiders it as rather belonging to the next than to this. See F. *collina*, var. *d*.

g. The Monthly or Alpine Strawberry. F. ſemperflorens; Ducheſne 49. Lam. Dict. n. 1. F. veſca *γ*; Willd. Sp. Pl. v. 2. 1091. Differs from the Wood Strawberry in having a rather leſs luxuriant herbage, while on the other hand it produces more abundant flowers and fruit, continuing in bearing to the very end of autumn, which renders it well worthy of cultivation. The fruit differs in nothing from the Wood Strawberry, being like that occaſionally white. This monthly variety is wild on the Alps, eſpecially, as it is ſaid, on Mount Cenis, where, indeed, it has but few months of open weather to bloſſom in. Ducheſne is diſpoſed to conſider this as the parent of the Wood Strawberry, and indeed the head of the whole family, becauſe of the vigour of its vegetation. This to us is rather paradoxical, eſpecially as he ſays it degenerates, which is not a ſymptom of a primary ſpecies, but the true teſt of a variety.

h. Engliſh Forcing Strawberry. Fragaria minor; Lam. Dict. n. 3. A dwarf variety, preferred for forcing in frames, of which there is alſo a ſort with white fruit. Ducheſne had it from England.

i. Freſſant's Strawberry. Fragaria hortenſis; Ducheſne 113. Lam. Dict. n. 4. This appears evidently, by Ducheſne's deſcription and ſpecimens, to be but a ſlight variety of the Wood Strawberry, raiſed accidentally from ſeed, whoſe fruit is 15 or 20 times larger than the wild kind, but of a fainter flavour in proportion. It abounds at Montreuil, where it was firſt raiſed by a man named Freſſant. Tournefort and Vaillant appear to have miſtaken this variety for the Fragaria parvi pruni magnitudine of Bauhin, or Hautboy Strawberry, our F. *elatior*. The fruit is occaſionally white. Freſſant's Strawberry was, according to Ducheſne in Lamarck, the only one to be found in the markets of Paris in 1790. Each root bears fruit but two ſucceſſive ſeaſons, and then periſhes, the preciſe kind being kept up from the runners, as in other caſes.

k. Strawberry without runners. Ducheſne 119. Fragaria efflagellis; Lam. Dict. n. 5. Sometimes called the buſhy ſtrawberry, as it forms luxuriant large tufts, but without runners, or with very few and ſhort ones.

l. Simple-leaved Strawberry. Fragaria monophylla; Ducheſne 124. Journ. d'Hiſt. Nat. v. 2. 343. t. 41. Uſt. Annal. faſc. 14. 40. t. 1. Lam. Dict. n. 6. Linn. Syſt. Veg. ed. 14. 476. Willd. Sp. Pl. v. 2. 1093. Ait. Hort. Kew. v. 2. 212. Curt. Mag. t. 63. Ducheſne moſt explicitly aſſures his readers, in the places here cited, that this is a variety raiſed by himſelf at Verſailles in 1761, from ſeed of the Wood Strawberry, and that when propagated by the ſame means, every generation returns more and more to the original ſpecies. Nothing can be more deciſive, and yet Linnæus, and after him Willdenow, retains it as a diſtinct ſpecies. Its appearance, indeed, is ſtriking, the leaves being ſimple and cordate, and the calyx ſingularly luxuriant and leafy. The fruit is like a fine Wood Strawberry. This variety increaſes very plentifully by runners.

2. F. *collina*. Green Strawberry. Ehrh. Beitr. n. 6. Willd. Sp. Pl. v. 2. 1093. (F. viridis; Ducheſne 135. Lam. Dict. n. 15. Ger. em. 998. Park. Parad. 528. F. veſca *a*; Linn. Fl. Lapp. ed. 2. 175. *β*; Fl. Suec. 175.) Calyx of the fruit erect, elongated, pointed. Hairs of the leaf-ſtalks widely ſpreading; thoſe of the partial flower-ſtalks erect.—Native of Sweden, Germany, and Switzerland. Ducheſne's ſpecimen has very much the habit and characters of the foregoing ſpecies, but differs in the *calyx*, which, after flowering, always remains erect, cloſely embracing the fruit, its ſegments being remarkably narrow, elongated, and pointed. The *fruit* is pale and greeniſh, with a yellow caſt, of a ſweet taſte and high flavour. Miller confounded this with the

the Pine Strawberry hereafter deſcribed, and in the lateſt edition of his Dictionary has left out the Green Strawberry, apparently from thinking it the ſame with the Pine, though nothing can be more unlike. Ehrhart, who ſeems to have known it in a wild ſtate, has eſtabliſhed it as a ſpecies, and Ducheſne's original ſpecimen anſwers to the above characters. The latter had his plants from England. We have not of late met with this Strawberry, but more than thirty years ago it was cultivated in an old garden at Watlington, Norfolk, and called the Pine Strawberry, probably in conſequence of Miller's error. Ehrhart ſeems to have been in doubt whether the Green Strawberry were the ſame with his *collina*, the *Bröſling* of the Germans; but as Ducheſne reckons it the beſt known of that race, or rather ſpecies, which he terms *Breſlinge*, we take it for the leading variety, and range the following under it.

a. German dark-leaved Strawberry. Fragaria nigra; Ducheſne in Lam. Dict. n. 12. F. minor, ſeu nigra; Thal. Harcyn. 43. Bröſsling, Fraga ſerotina; Camer. Kreuterb. 335, 2. Bauh. Hiſt. v. 2. 394. Harbeer; ibid. 395. Fragaria foliis hiſpidis; Rupp. Jen. ed. Hall. 108. F. ε, Preſling; Hall. Hiſt. v. 2. 44. F. β; Hall. Gott. 108. F. fructu majori candicante oblongiuſculo; Volck. Noriberg. 172. Fragum album; Tabern. Kreuterb. 346. f. 2.—This might perhaps, more properly than the Green Strawberry, be deemed the original ſpecies, being certainly in a wild ſtate. It is called *nigra* by Thalius and Ducheſne, on account of the dark hue of the leaves. The latter mentions having had roots from Haller, and that the *fruit* adheres firmly to the calyx. Its colour is green, tinged of a browniſh red on the ſide expoſed to the ſun. The flavour almoſt too highly perfumed. The pulp ſwells much between the ſeeds. The *leaves* are low and very brown, often in five parts. It is late, and a bad bearer, and ſeems to want improvement by culture, yet when raiſed from ſeed for ſome years, Ducheſne found no amendment in its quality. The German writers above quoted in general ſpeak of the fruit as white, but often tinged with red on the ſunny ſide. The only figure we can find is that of Tabernemontanus, which we have cited on account of the erect, narrow, elongated calyx, which conſtitutes the character of the preſent ſpecies and all its genuine varieties.

b. Burgundy Strawberry. Fragaria pendula; Ducheſne in Lam. Dict. n. 13. Called Fraiſier-marteau, or Hammer Strawberry, from the ſhape of its fruit, which is rather more coloured than in the former variety, with a leſs powerful flavour. No ſeeds are produced on that part of the fruit covered by the calyx. It was received from Burgundy in 1768, and is conſidered, even by Ducheſne himſelf, as very near the laſt variety.

c. Rough-leaved Strawberry, Fragaria hiſpida; Ducheſne in Lam. Dict. n. 14. F. foliis hiſpidis; Bauh. Pin. 327. Mapp. Alſat. 110. Fraga partim rubra partim candida; Trag. Hiſt. 500. We cannot clearly perceive how this variety differs from our firſt, *a*, nor can we at all diſtinguiſh their ſynonyms. Ehrhart clearly unites them, and we mention them ſeparately rather out of deference to Ducheſne, who ſays the *leaves* are very rough, the *fruit* more elongated, more coloured, more juicy, and better than in our *a* and *b*; but the plant is often barren in the bois de Boulogne near Paris, where it grows in a ſtate of nature, having poſſibly come out of the adjoining gardens made by Francis I.

d. Fragaria abortiva; Ducheſne in Lam. Dict. n. 11, which we have mentioned, according to that writer's original opinion, under the former ſpecies, variety *f*, ſeems rather, by the calyx of his ſpecimen, to belong to the preſent, as he now ſeems diſpoſed to conſider it. As however it is probable that both ſpecies may be ſubject to the ſame diſeaſe, and therefore we have ventured to indicate it under each.

e. Swediſh Strawberry. Fragaria pratenſis; Ducheſne in Lam. Dict. n. 16. F. veſca β, pratenſis; Linn. Sp. Pl. 709. γ; Fl. Lapp. ed. 2. 176. Fl. Suec. 175. F. fructu parvi pruni magnitudine; Rudb. Act. Suec. ann. 1720. 97, but not of Bauhin. We place this here on the authority of Ducheſne, who informs us he received roots from Linnæus in 1765, which ſucceeded well, and the race remained unaltered when propagated by ſeed, except that the fruit was ſometimes encreaſed in ſize. "It has ſmaller *ſhoots* and more contracted *runners* than any other ſtrawberry, with a low and mean *foliage*, which dies and diſappears entirely in winter, a circumſtance peculiar to this variety. The *fruit*, however, is pretty large, bright green with a very deep red tinge, perfectly round, firmly fixed to the calyx, ſo as to make a noiſe when pulled from it. The pulp is ſolid, friable, very juicy, exquiſitely perfumed, and much ſwelled between the ſeeds, which are very large. It is rather late in ripening, but bloſſoms again directly, and often perfects a ſecond crop of fruit. The firſt bloſſoms come out of the ground like an Anemone, before the leaves are fully grown."—We find in the Linnæan herbarium under *F. veſca*, two ſpecimens anſwering to this deſcription, and their petals are twice as large as the real *F. veſca* or wood ſtrawberry which accompanies them, on another ſheet of paper, and is preciſely our Engliſh kind. The *leaves* of the former are extremely ſilky at the back, and have the ſhort terminal tooth mentioned by Ehrhart as a character of his *F. collina*, but on this laſt mark we would not lay much ſtreſs in this genus. The *fruit* in the Linnæan ſpecimen is unluckily not far enough advanced for us to decide whether the calyx in that ſtate be erect or not, ſo that we can at preſent only rely on Ducheſne for its belonging to this ſpecies and not to the wood ſtrawberry, nor to the Hautboy hereafter mentioned, the calyx of both which, when in fruit, is ſhort and reflexed. Linnæus ſays this plant grows in meadows clothed with ſhort graſs. It is leſs common than the wood ſtrawberry, and not ſo fragrant, but both are eaten promiſcuouſly.

f. Provençal Strawberry, or Majaufe. Fragaria bifera; Ducheſne in Lam. Dict. n. 9. F. in alpibus Bargeis, bis in anno fructificans; Cæſalp. de Plant. 554. This is deſcribed by Cæſalpinus, whom other authors have copied, as bearing fruit which is moderately compreſſed and ſtriated, with the taſte of a raſpberry. Ducheſne procured plants in 1766 from the neighbourhood of Bargemon. In a wild ſtate this kind produces fruit in the ſpring and autumn, but almoſt all the year round in a garden, which renders it very deſirable for cultivation, eſpecially as it laſts five or ſix years without being freſh planted. The *fruit* is rather large, round, often flattened on the ſhady ſide, of a reddiſh yellow, except where the ſun colours it of a deep red. The part covered by the calyx remains whitiſh, repreſenting a ſtar at the baſe. It has a peculiar perfume.

g. Champagne Strawberry. Fragaria dubia; ibid. n. 10. "This variety," ſays Ducheſne, "which is found about Ferté-ſous-Jouarre, upon little hills, not in woods, is much leſs robuſt than the preceding. Its *fruit* is more flattened, higher coloured, and very vinous. It is difficult to diſtinguiſh this kind of Majaufe from the ſtrawberries properly ſo called (*F. veſca* and its varieties), and its exiſtence leads us much to doubt of the diſtinction of theſe two kinds from thoſe. This Champagne Majaufe is leſs fruitful than that of Provence. It bears fewer flowers, and is moreover very ſubject to incomplete, or even total, ſterility. When raiſed from ſeed, very few fertile individuals are produced, and there

were

were ſome ſterile ones among thoſe ſent us from the country in 1767." Theſe remarks render it doubtful to which diſtinct ſpecies of *Fragaria* the variety here deſcribed may belong, but reſpecting the laſt, the poſition of the calyx puts it out of doubt.

3. F. *virginiana*. Scarlet Strawberry. Mill. Dict. ed. 8. n. 2. Ehrh. Beitr. n. 3. Willd. Sp. Pl. v. 2. 1091. Ducheſne 204. Lam. Dict. n. 24. (F. veſca δ; Ait. Hort. Kew. v. 2. 211. F. virginiana, fructu coccineo; Moriſ. v. 2. 186. F. glabra, fructu coccineo majore, ſeminibus in cortice loculoſo altiùs depreſſis, virginiana; Duham. Arb. Fruit. v. 1. 181. t. 5.)—Calyx of the fruit ſpreading. Hairs of the leaf-ſtalks, and of all the flower-ſtalks, erect. Leaves nearly ſmooth on their upper ſurface.—Native of Virginia. *Clayton*. This in our gardens is one of the beſt known and moſt valuable kinds, on account of its plentiful bearing, hardineſs, earlineſs, and grateful flavour, as well as the facility with which it is forced. The *leaves* are larger and ſmoother than thoſe of *F. veſca*. *Flowers* leſs expanded, but more copious, forming a denſe ſort of corymbus, and each ſtanding on an elongated ſlender ſtalk, whoſe hairs are erect, almoſt indeed cloſe-preſſed, as are all thoſe likewiſe on the common flower-ſtalks and on the leaf-ſtalks, affording an excellent ſpecific character. The peculiar ſcarlet colour of the *fruit* is well known. Its ſurface ſwells between the ſeeds, making little cells in which they are lodged. No white, nor any other variety of this ſpecies, except a ſlight variation in the internal redneſs of the fruit, is known in Europe. Linnæus ſeems to have been ſcarcely at all acquainted with the Scarlet Strawberry, not having mentioned it, even as a variety, except in his Hortus Cliffortianus. Ducheſne complains that this Strawberry is too juicy and tender to bear carriage, or be brought to market, but we find no ſuch difficulty in England, though it is certainly more tender than moſt others. Its perfume, when confined or over powerful, becomes intolerable to moſt people, and however grateful this fruit may be to perſons in general, there are perſons to whom one or two Scarlet Strawberries is an actual poiſon. The calyx enfolds the unripe fruit in this ſpecies, without touching it, but becomes ſubſequently expanded.

4. F. *elatior*. Hautboy Strawberry. Ehrh. Beitr. n. 2. Willd. Sp. Pl. v. 2. 1091. (F. moſchata; Ducheſne 145. moſchata dioica; Lam. Dict. n. 18. F. veſca β, pratenſis; Retz. Obſ. faſc. 6. 30. F. fructu parvi pruni magnitudine; Bauh. Pin. 327. F. muricata; Mill. Dict. ed. 8. n. 3. F. et fraga; Lob. Ic. v. 1. 697. Dod. Pempt. 672. Ger. em. 997. f. 2. F. major et minor; Fuchs. Hiſt. 853. Fraga bohemica maxima; Park. Parad. 527. f. 7.)—Calyx of the fruit reflexed. Hairs of the leaf-ſtalks, and of all the flower-ſtalks, widely ſpreading, ſomewhat deflexed.—The native country of this fine ſpecies has been enveloped in great uncertainty. Miller declares it to be of American origin, which Ehrhart copies with a doubt. Some old authors reported that it came from Hungary and Bohemia, which we are diſpoſed to believe, becauſe ſo many of the early writers have figured this ſpecies and not the *F. veſca*; and we are aſſured by Mr. Dickſon, Mr. Jackſon, and Mr. Anderſon, all excellent practical botaniſts, that it is certainly wild near Tring in Hertfordſhire, on the weſt ſide of that town. Mr. W. Borrer alſo finds it in Charlton foreſt, Suſſex. It may therefore be a native of other parts of Europe, though often overlooked for the Wood Strawberry, and not detected even by the indefatigable Ehrhart. No ſpecies of any genus can be better defined than this. The direction of the copious hairs on all the *flower-ſtalks*, both general and partial, as well as on the leaf-ſtalks, being widely ſpreading, or rather pointing downwards, affords a clear ſpecific character, permanent in the dried as well as freſh ſpecimens. The *calyx* of the fruit is ſhort and reflexed, much like that of the Wood Strawberry. The whole *herb* is larger and ſtronger than in any of the foregoing ſpecies. Common *flower-ſtalks* tall, ſtrong, moſtly compreſſed. *Flowers* large, ſpreading, generally but not always imperfectly dioecious, the ſtamens being moſt effective on one plant, the piſtils on another, ſo that the gardeners uſually find it neceſſary to cultivate both ſexes, and hence the produce of the ſame extent of ground is not ſo great as in the *F. veſca* or *virginiana*. This ſexual difference was firſt obſerved by Ducheſne, whom Linnæus cautioned againſt being miſled by flowers rendered abortive by cold in the ſpring; but the former was correct. The *fruit* is large, roundiſh, of a dark dull crimſon, with a high muſky perfume, but leſs of acid pungency than either of theſe juſt mentioned, palling on the palate as that perfume gradually becomes leſs ſenſible, and a mawkiſh flavour ſucceeds. The fleſh is ſolid, firmly fixed to the calyx, without any central cavity. Its ſurface is pitted, but leſs than in the Scarlet Strawberry. M. Ducheſne remarks in his firſt publication, that this ſpecies is not ſubject to any remarkable varieties, but in Lamarck he mentions ſome ſlight ones; in which latter work he moreover corrects his former miſtake, of making the Swediſh *F. veſca pratenſis* of Linnæus, (our *F. collina*) the ſame with the Hautboy, an error in which Ehrhart and Retzius have remained. The failure of the fruit of the Hautboy, which has been obſerved to dwindle away, ſeems owing to a neglect of the cultivation of the male plants, becauſe they were obſerved not to bear fruit. Hence the females were unfruitful for want of impregnation. The old wooden cuts above quoted clearly expreſs the Hautboy Strawberry, and not the Wood or Scarlet, the hairs of the ſtalks, and their direction, being very faithfully delineated.—In the herbarium of Linnæus is a ſpecimen of the ſpecies of which we are treating, without a name, but marked by himſelf as gathered at Lund in Scania. But unfortunately on the ſame paper is one of the Scarlet, ſo that we cannot preſume the former to be wild, as the latter aſſuredly is not. They were perhaps ſent him by Retzius, who has publiſhed a ſhort remark, quoted above, on the dioecious nature of the Hautboy.

a. Royal Hautboy. Fragaria moſchata; Ducheſne in Lam. Dict. n. 17. Of this we know nothing but from the author here cited, who ſuſpects it may be a hybrid production between the Hautboy and ſome variety of the *F. collina*. Of this he had met with another inſtance, in which a very delicious and juicy little ſtrawberry was produced, but the plants ſoon became ſterile. The preſent however proves luxuriant and prolific, bearing two crops in a year, of light-coloured firm fruit. The flowers are not dioecious in this variety.

5. F. *grandiflora*. Pine Strawberry. Ehrh. Beitr. n. 4. Willd. Sp. Pl. v. 2. 1092. (F. Ananaſſa; Ducheſne, 190. Lam. Dict. n. 20? F. veſca ε; Ait. Hort. Kew. v. 2. 212. F. Foliis ovatis crenatis nervoſis, calycibus maximis; Mill. Ic. 192. t. 288.)—Calyx of the fruit erect. Hairs of the leaf-ſtalks, and of the common flower-ſtalks, upright; thoſe of the partial ones rather ſpreading. Leaves ſmooth above; their ſerratures ovate.—We cannot but think Ducheſne's original account of this ſtrawberry more correct than what he has given in Lamarck. He juſtly preſumed it a native of Louiſiana, rather than of Surinam, to which common report has attributed it. It is now not unuſually cultivated near London. In habit this moſt agrees with the Hautboy; but in botanical characters, though not at all in habit or qualities, with the ſcarlet: and thoſe characters are ſo ſpecific,

cific, that we can by no means aſſent to the conjecture of its having originated in a garden at Harlem.

F. *grandiflora* is one of the largeſt kinds, vyeing in that reſpect with the Chili Strawberry, hereafter deſcribed, but differing from that in the greater ſmoothneſs of its herbage. The *leaves* are large, firm, obtuſe, with large, ovate, bluntiſh ſerratures, very unlike thoſe of the Scarlet, though like them they are nearly or quite ſmooth on their upper ſurface; beneath they are ſomewhat pale, and ſlightly hairy. The hairs on their *foot-ſtalks* are long, fine, and upright, not cloſe-preſſed; thoſe of the general *flower-ſtalks* are rather more inclined to ſpread, and thoſe of the partial ones even more ſo, but not in ſuch a degree as to become horizontal. The *flowers* are numerous, large and cymoſe, often having ſix petals, and a correſponding number of other parts. *Fruit* more like the Hautboy than the Scarlet, very large, of a pale red, approaching to fleſh-colour, firm, and adhering to the calyx, but hollow in the centre; its ſurface ſcarcely pitted, very highly poliſhed. The flavour is very fine, and, in our opinion, preferable to the Hautboy. It will readily be perceived by this deſcription how different this ſpecies is from the Green Strawberry, F. *collina*, with which it has in the name of Pine-Strawberry been ſometimes confounded.—The leaves are occaſionally variegated. The hue of the fruit varies a little, but is always of a more or leſs pale crimſon or purpliſh caſt, not verging towards ſcarlet.

a. Bath Strawberry. Fragaria calyculata; Ducheſne in Lam. Dict. n. 21. A rather ſtronger variety than the former with a large *calyx*, and rugged or pitted *fruit*. Ducheſne now quotes Miller's t. 288. under this variety. *b.* Mule Strawberry. Fragaria hybrida; ibid. n. 25. Suppoſed to have been produced between the Pine and the Scarlet. It is early, but a bad bearer.

6. F. *chiloenſis*. Chili Strawberry. Ehrh. Beitr. n. 5. Willd. Sp. Pl. v. 2. 1092. Ducheſne 165. Lam. Dict. n. 19. (F. veſca γ; Linn. Sp. Pl. 709. Ait. Hort. Kew. v. 2. 211. F. chiloenſis, fructu maximo, foliis carnoſis hirſutis; Dill. Elth. 145. t. 120.)—Calyx of the fruit erect. Hairs of the leaf-ſtalks, and of the common flower-ſtalks, deflexed; thoſe of the partial ones horizontal. Serratures of the leaves broader than long.—Native of Chili, where it is called by the Spaniards *Frutilla*, or little fruit. It was brought from that country to France in 1712, or 1716, by M. Frezier, and thence found its way into various European gardens. It flowered in that of Eltham in 1730, where Dillenius made his deſcription and very accurate figure, in which the peculiar direction of the pubeſcence, affording a certain ſpecific diſtinction, is faithfully expreſſed, as well as the true ſhape of the ſerratures of the leaves. This Strawberry is now one of the moſt common, immediately ſucceeding the Scarlet at our tables, and known by the name of Carolina Strawberry, rather than by its true appellation. Some gardeners have attempted to transfer the name of Hautboy to the preſent; that the true Hautboy, being leſs profitable, might become obſolete and be forgotten. The Chili Strawberry is as large in all its parts as any other kind, and rather larger in its *ſtalks* and *bloſſoms*. The *leaves* are of moderate dimenſions, but firm and ſomewhat rigid, veiny; almoſt ſmooth above, paler and very hairy beneath. Their ſerratures are broader, ſhorter, and more rounded than in any other ſpecies, ſo that they might almoſt be called crenate. The copious hairs of their *foot-ſtalks* are all directed ſtrongly downwards, and thoſe of the general *flower-ſtalks* are nearly equally ſo; but the more denſe hairs of the partial ſtalks project horizontally. The *flowers* are often luxuriant in the number of their parts. They appear by the report of Ducheſne to be ſometimes dioecious, but of this we never ſaw any ſigns, the varieties with which we are acquainted being good bearers. The *calyx* is cloſed after flowering, and embraces the ripe *fruit*, which is large, ovate, often compreſſed and abrupt, of a ſcarlet rather than crimſon hue, ſtudded with innumerable ſeeds; its inſide is ſpongy towards the middle, and uſually white. The flavour is gratefully acid, with rather leſs of perfume than the other kinds. Frezier ſays the fruit is ſometimes in Chili as big as a hen's egg. It is remarkable that this kind was ſo ſcarce in France, when Ducheſne publiſhed his book in 1766, though introduced fifty years before, that he tells us he had taſted only a very imperfect and abortive one.

a. Carolina Strawberry. Fragaria carolinienſis: Ducheſne, in Lam. Dict. n. 22. We perceive little in Ducheſne's deſcription, by which this can be diſtinguiſhed from the Chili; nor can we imagine why he has ranged the Pine and Bath Strawberries between them. What we have ſaid above of the Chili anſwers to this; for the ſlight differences which occur in every garden, as to the ſhape or colour of the fruit, are certainly very immaterial and tranſient.

b. Canterbury, or Red-fleſhed Strawberry. Fragaria tincta; ibid. n. 23. Differs from the laſt variety merely in the crimſon hue, with which the fruit is ſtained to the very centre.

Such are all the known ſpecies, and principal varieties of eatable Strawberries. We ſhall finiſh our hiſtory of the genus with one that is altogether unprofitable, as its name imports.

7. F. *ſterilis*. Barren Strawberry. Linn. Sp. Pl. 709. Curt. Lond. faſc. 3. t. 30. Engl. Bot. t. 1785. (F. minimè veſca, ſive ſterilis; Ger. em. 998.)—Stem decumbent. Flowering-branches weak, each bearing one or two flowers. Fruit juiceleſs.—Native of dry gravelly paſtures, throughout the middle and ſouthern parts of Europe; very common in England, flowering in March and April. This is a ſmaller plant than any of the foregoing, and eſſentially diſtinguiſhed from all of them by its decumbent *ſtem*, deſtitute of runners, and by the flowering branches bearing one or two leaves, and only one or two *flowers*. The *leaflets* are obovate, ſharply ſerrated, moſt ſilky beneath. The hairs on their *foot-ſtalks* ſpread horizontally, as do thoſe on the *flower-ſtalks*. The *flowers* are ſnow-white, ſmall and delicate, with a hairy *calyx*. *Receptacle* of the ſeeds ſmall and dry, ſcarcely deciduous as the generic character requires, yet it is preſent. *Seeds* ſmooth, or very ſlightly wrinkled.—Some difficulties attend the generic arrangement of this ſpecies, yet it has the preciſe habit and characters of a *Fragaria*, except the dry receptacle. In this laſt reſpect it agrees with *Potentilla*; and indeed Haller refers the whole of the latter genus, with *Tormentilla*, *Comarum*, and *Sibbaldia* of Linnæus, to *Fragaria*, as Ludwig, Boehmer, Scopoli, and Crantz have done. In this, nature is entirely ſacrificed. We preſume to think that the Linnæan genera, in this natural order of *roſaceæ*, are among the moſt natural and beſt defined of the whole ſyſtem.

In Mr. Andrews's Repoſitory, t. 479, is deſcribed and figured a plant from the north-eaſt part of Bengal, by the name of *Fragaria indica*. This was found on the Nepal mountains, by Dr. Buchanan, from whom we have it. The *ſtem* is creeping, like *Potentilla reptans*; *leaves* ternate; *flowers* axillary, ſolitary, ſtalked, with yellow petals, and a red pulpy *fruit*. The latter, nevertheleſs, is totally different from a *Fragaria*, and is nearly, if not entirely, the fruit of a Rubus, being compoſed of ſeparate juicy grains, in each of which a ſeed is lodged. The *calyx*, however, being in ten ſegments, five larger and five ſmaller, as in *Fragaria* and *Potentilla*, differs eſſentially from that of a *Rubus*,

from

from which alſo the habit is altogether diſſimilar. This plant, indeed, conſtitutes an entirely new genus, and we propoſe to call it *Ducheſnea fragiformis*, in memory of a writer who has thrown ſo much light on its near relation, *Fragaria*. S.

FRAGARIA, in *Gardening*, compriſes a plant of the low, herbaceous, perennial, hardy fruit kind.

Of which the ſpecies moſtly cultivated is the eſculent ſtrawberry (*F. veſca*), of which there are ſeveral varieties in cultivation, but the following are the principal.

The wood-ſtrawberry, which has the leaflets oval-lanceolate, acutely ſerrate; the petioles woolly; the runners ſlender, ſmooth, often tinged with purple; peduncles with two or more flowers. The fruit ſmall, and uſually red; it has commonly little flavour here, from the plants being too much ſhaded in the woods and hedges. The ſub-varieties of which are, the white wood-ſtrawberry, which ripens a little later in the ſeaſon, and is often preferred to it for its quick flavour; but as it ſeldom produces ſuch large crops of fruit as the red ſort, it is not ſo generally cultivated.

The alpine ſtrawberry, which is a larger plant than that which grows in woods, the ſtem higher, the leaves broader, the fruit larger, red, and uſually much pointed, ſometimes white. It is well flavoured, and the plants continue long in bearing, which renders them very valuable. The reaſon of this is, that the runners which it throws out during the ſummer ſhoot up into flower and fruit the ſame year more freely than in the other ſorts. It is ſometimes termed everlaſting ſtrawberry.

The rough-fruited, or prickly ſtrawberry, which Martyn thinks nothing but an accidental variety, has the flower greeniſh; the fruit harſh, rough and prickly, of a greeniſh colour, with ſome ſhow of redneſs.

The hautboy-ſtrawberry is very different from the reſt in leaf, flower, and fruit. The leaves are larger, thicker, hairyiſh, and rough. The fruit very large, and of a pale red colour. It varies with oval, fine-ſhaped, and green fruit; with red bloſſom, with white-ſtriped leaves, and with yellow-ſtriped leaves.

There is alſo an improved ſub-variety of it, called globe-hautboy; the fruit of which is larger, and of a globular form. Martyn has obſerved, that "where theſe are neglected, they degenerate to the common hautboy; but where the ſoil is good, and the culture well managed, the plant will produce a great quantity of large well-flavoured fruit."

But this variety of ſtrawberry is very apt to degenerate, and to produce only dry effete fruit; which, according to Monſ. Duhamel, is owing to there being two ſorts of plants, one bearing male, the other female, or rather imperfect hermaphrodite flowers; the former of which, being reputed uſeleſs, are carefully deſtroyed; hence not only the ſeeds become abortive, but the receptacle, commonly called the fruit, ſmall and juiceleſs. This Martyn thinks "may be remedied, either by planting a few of the male plants, or of the ſcarlet, or pine ſtrawberry, among the hautboys."

The Chili ſtrawberry has the leaves hairy, oval, and of a much thicker ſubſtance than any ſort yet known, and ſtands upon very ſtrong, hairy foot-ſtalks; the runners from the plants are very large, hairy, and extend to a great length, putting out plants at ſeveral diſtances. The peduncles are very ſtrong; the leaves of the calyx long and hairy. The flowers are large, and often deformed; and ſo is the fruit, which is very large. When cultivated in very ſtrong land, the plants produce plenty of firm, well-flavoured fruit; but as it is a bad bearer in moſt places, it has been lately leſs cultivated than formerly.

According to Frezier, the fruit uſually attains the ſize of a walnut, but is ſometimes as large as an egg, of a paler red than the European ſtrawberry, and not ſo quick in its flavour. It deſerves cultivation for the ſingularity and ſize of the fruit. And it varies with round pale red, with globular pale red, with oblong-oval pale red, and deep red fruit. There is alſo the Carolina, ſcarlet, and white-fruited; the royal large red; the large Dutch, Bath, and Devonſhire Chili ſtrawberry.

The ſcarlet ſtrawberry, which is the ſort firſt ripe. The fruit is good, being preferred to moſt others by many. It was brought from Virginia, where it grows naturally in the woods. It is very different from the wood ſtrawberry in leaf, flower, and fruit; the leaves being of a dark green, and of a more even ſurface, the flowering-ſtems ſhorter, the fruit being frequently concealed among the leaves; and it varies with roundiſh leaves and with ſtriped leaves.

The pine ſtrawberry, in which the leaves have a great reſemblance to thoſe of the ſcarlet ſtrawberry, but are larger, of a thicker ſubſtance, and the indentures of their edges blunter; the runners are much larger, and hairy; the peduncles are ſtronger; the flowers much larger; and the fruit approaches in ſize, ſhape, and colour, to the Chili ſtrawberry. It produces a great quantity of fine, large fruit, when the plants are kept clear from runners during the proper ſeaſon.

According to Monſ. Duhamel, it is raiſed from the ſeed of the Chili ſtrawberry. The flower is very large, and the fruit has ſomething of the ſmell and taſte of the pine-apple. It varies in the form of the fruit with ovoid, with oblate-ſpheroid, and with irregular fruit. It is much ſmaller than the Chili ſtrawberry. There are alſo the green, red, and hautboy-fruited, as well as the Chili pine-apple ſtrawberry.

The Carolina ſtrawberry, which greatly reſembles the above, but is much leſs in all its parts, and leſs hairy; the flower-ſtems are ſhorter; the flower-buds more lengthened out, and leſs ſwoln; the fruit ſmaller, more regular in the form, of a higher colour, but the perfume not ſo pleaſant. Martyn remarks, that the pine varies little when raiſed from ſeed, whereas this varies much in the flower, fruits, and other parts.

It is not improbable but that there may be many other varieties and ſub-varieties of this fruit which may be highly deſerving of cultivation.

The wood and alpine ſorts, in general, bear beſt when raiſed from ſeed, and planted in a rich light earth of a browniſh caſt. The ſcarlet, the hautboy, the Carolina, and the Chili, anſwer beſt on ſtrong mellow loams.

Method of Culture.—In order to raiſe this ſort of fruit to the greateſt advantage and perfection, the ſoil ſhould be of the friable loamy kind, with a moderate degree of moiſture, but by no means wet.

All the different varieties and ſub-varieties may be made uſe of where large ſupplies are wanted; but in other caſes, a few of the ſmall and large ſorts may be ſufficient. The ſame varieties ſhould always be planted together in ſeparate beds, or other places; but never any mixture of different ſorts admitted in the ſame ſituations.

The moſt uſual practice, in forming beds of this ſort of fruit, is by planting out the off-ſets taken from the ſides of the old plants, or ſuch as are formed from the rooting of the joints of the runners; but the former are, in general, the better plants. And in chooſing them, they ſhould never be taken from ſuch plants as are old, and which have been neglected in their culture, but conſtantly from ſuch as have been well kept in order, and are in a full bearing ſtate; ſuch

off-ſets as ſtand neareſt to the old plants being preferred to ſuch plants as are formed by the trailing ſtems at a diſtance. Upon a careful attention to theſe circumſtances, much of the ſucceſs of this ſort of culture depends. In ſome of the varieties, as thoſe of the wood kind, the off-ſets are beſt when taken from the wild bearing plants; as they are not ſo liable to run as thoſe taken from the cultivated ſorts.

Theſe off-ſets or plants are moſtly of ſufficiently ſtrong growth the firſt year for being made uſe of; but when this is not the caſe, they may be ſet out in nurſery-rows till they have obtained a full growth, and are in the moſt proper ſtate for being ſet out.

In preparing for plantations of this ſort, the ground ſhould be well trenched over, and effectually cleared from all ſorts of weeds, and, after being laid quite level, formed into beds four feet in width, with paths of two feet or two feet and a half between them, for the convenience of cultivation and gathering the produce. The ſituation ſhould be quite open, and have as much as poſſible a ſouthern aſpect. It is likewiſe a great advantage when the beds can be formed in a ſhelving or ſloping manner towards the ſouth, ſo as to have the full influence of the ſun during the day.

When the beds have been thus made up, they are in a proper ſtate for being planted upon, which ſhould be done as ſoon as poſſible.

The moſt ſuitable time for performing this buſineſs is in the early autumn, as about the latter end of September, or beginning of the following month, in order that the plants may be well rooted before the commencement of the winter froſts. Some, however, plant in the early ſpring; but there is more danger of the plants being deſtroyed by the heat of the ſummer at this ſeaſon.

In executing the work, the plants or off-ſets ſhould be put in by means of a line and dibble, in rows lengthways of the beds, at different diſtances, according to the kinds.

The moſt uſual diſtances are, for the wood ſort, twelve or fifteen inches each way; and eighteen inches for the ſcarlets, hautboys, Chili, alpine, and other large kinds. Much advantage is always gained by letting them have ſufficient room. It is uſual to ſet them out in the quincunx order; and great care ſhould be taken, in the work of planting, to cloſe the mould well to the roots of the plants, as they are ſet out. When the whole has been done, they ſhould have a good watering, to ſettle the earth well about their roots, and keep them ſteady in the ground.

But beſides this mode of planting upon beds, they ſucceed well on the fronts of clumps, borders, and other parts of pleaſure-grounds, eſpecially when ſet ſo as to have a due degree of ſun, and without being too much ſhaded by the trees and ſhrubs.

When new varieties of this ſort of fruit are wanted, the propagation muſt be effected by ſowing the ſeed produced on the fruit, when perfectly ripened, either in the ſpring or autumnal ſeaſon, on a bed of light earth, or in pots placed in the ſhade.

After the plants have been ſet out as above, and taken new root, care is neceſſary, if the winter prove ſevere, to lay ſome old tanner's bark over the ſurface of the bed between the plants, to keep out the froſt. This is abſolutely neceſſary in the Chili ſort, as the plants are frequently killed in hard winters, when expoſed without any covering. Where tanner's bark cannot be eaſily procured, ſaw-duſt or ſea-coal aſhes may be uſed, or even decayed leaves of trees, or the branches of ever-green trees, with their leaves upon them, laid over the beds, or other parts.

And in the following ſummer, the plants ſhould be conſtantly kept clean from weeds, and all the runners be pulled off as faſt as they are produced: as, where this is conſtantly practiſed, the plants become very ſtrong by the following autumn; but when neglected, and the runners are permitted to ſtand during the ſummer, and then pulled off in the autumn, they are not half ſo ſtrong, nor will there be near the ſame quantity of fruit upon them the following ſpring, or ſo large and fine. Where proper care is taken of the plants the firſt ſummer, there is generally a plentiful ſupply of fruit the ſecond ſpring after planting.

When the plants are in bloſſom, if the weather prove dry, good waterings, given occaſionally, prove very beneficial in promoting a plentiful production of fruit; but, in other caſes, it is unneceſſary to be had recourſe to.

But in the general culture of this ſort of fruit, as the old plants are thoſe which produce the fruit, the ſuckers ſeldom affording any till of a full year's growth, it is obviouſly neceſſary to diveſt them of them; as, when ſuffered to remain, they rob the fruitful plants of their nouriſhment, in proportion to their number; and beſides, the ſuckers render each other weak, and thus cauſe barrenneſs. In the alpine ſorts, the ſummer runners ſhould not, however, be removed, as they produce fruit.

After having been thus cut and managed in the ſummer ſeaſon, it will be neceſſary, in autumn, not only again to diveſt them of theſe ſtrings or runners, but of all the decayed leaves, and to clear the beds from weeds; then the paths ſhould be dug up, and the weeds buried, ſome earth being laid over the ſurface of the beds between the plants, which will ſtrengthen them, and prepare them for the following ſpring; and if, after this, there be ſome old tanner's bark laid over the ſurface of the ground between the plants, it will be of great ſervice to them. In the ſpring, when the danger of hard froſt is over, as in March, the ground between the plants in the beds ſhould be forked over with a narrow three-pronged fork, to looſen it and break the clods; and in this operation the tan, which was laid over the ſurface of the ground in autumn, will be buried, and be a good dreſſing to the ſtrawberries, eſpecially in ſtrong land. This ſhould be done whether the plants are in diſtinct bunches or in large beds, being equally neceſſary in all caſes.

And about the beginning of April, Martyn has obſerved, "if the ſurface of the beds be covered with moſs, it will keep the ground moiſt, and prevent the drying winds from penetrating the ground, and thereby ſecure a good crop of fruit, and alſo preſerve the fruit clean, that when heavy rains fall after it is full grown, there will be no dirt waſhed over them, which frequently happens, ſo that it muſt be waſhed before it is fit for the table, which greatly diminiſhes its flavour."

It is of great utility in dry ſeaſons to water occaſionally every ſummer, while the plants are in blow and forming their fruit; but as it approaches maturity, this ſhould be left off, as it injures the flavour of the fruit.

But in ſome of the more fine ſorts, or curious large varieties, when ripening, it is eligible either to tie up the ſtalks with the bunches of fruit thereon to ſticks, or the leaves and ſtalks together; ſo as, in either way, to elevate the fruit from the earth, more out of danger of rotting by wet, if a rainy ſeaſon, and to more effectually enjoy the full ſun to ripen with a good flavour; or, ſometimes place flat tiles on the ground, round each plant of a few particular ſorts, for the fruit to reſt upon, drier, and more ſecure from rotting by the damp of the earth, and to ripen with an improved flavour by ſuch means.

As the fruit ripens in June and the following months, it ſhould be gathered daily; being plucked off in the cup, with about half an inch of the ſtalk adhering, by which

means they are not ſo liable to be bruiſed, and appear more conveniently when ſerved at table, and are more agreeably picked up out of the diſh or baſket for eating. The wood ſtrawberries are, however, very commonly gathered without any ſtalky part, being generally picked clean out of their cups, eſpecially when deſigned to eat with cream, &c.

Method of Culture in Hot-houſes, &c.—Beſides the above method of raiſing this ſort of fruit in the natural ground, it may be brought to perfection at a much earlier period, by forcing in hot-houſes, glaſs-frames, againſt hot walls, and under common dung or bark hot-bed frames, &c.; but they ſucceed beſt in the ſucceſſion pine-apple houſe.

The ſorts moſt ſuitable in this intention are the different ſmaller ſorts, as the ſcarlet, the alpine, and the wood ſtrawberry. The hautboy grows too large for this purpoſe.

In providing ſets, great care ſhould be taken to have them from the moſt fruitful plants, and thoſe which grow immediately on the old plants; they ſhould be taken off in autumn, and each planted in a ſeparate ſmall pot filled with loamy earth, being placed in a ſhady ſituation till they have taken root; after which they may be removed to an open ſituation till the middle or end of November, when the pots ſhould be plunged into the ground up to their rims, to prevent the froſt from penetrating through the ſides. When placed near a wall, pale, or hedge-fence, expoſed to the eaſt or north-eaſt, they ſucceed better than in a warm ſituation, as they are not forced too forward; after this they only require to be ſecured againſt froſt.

In the ſpring following the plants will have filled the pots with their roots by the end of April, when they ſhould be turned out of them and their roots pared, and re-planted into penny pots filled with the like loamy ſoil, and re-plunged into the ground, in a ſhady ſituation, to remain till the following ſummer; during which time they muſt be kept clean from weeds, and have all the runners taken off as faſt as they are produced. And if there ſhould be any flowers produced, they ſhould be pinched off, in order to have the plants as ſtrong as poſſible.

Towards the end of October, or earlier, if the ſeaſon prove cold, the pots ſhould be removed into a warmer ſituation, to prepare them for forcing; as they ſhould not be ſuddenly removed from a very cold ſituation into the ſtove or hot-bed, but be gradually prepared for it. Where they are deſigned for the borders near hot walls, they may then be turned out of the pots and planted, that they may have time to get freſh rooted before the fires are made to heat the walls; and they may be placed very cloſe to each other, as they are deſigned to remain there only till they have ripened their fruit. It is always the beſt way to pot the plants a year before they are forced.

When the fires are lighted about the latter end of December the ſtrawberries in the borders will be ripe the end of March; but if the ſeaſon ſhould prove very cold, it will be the middle of April before they are fit for the table.

When intended to be forced in a pine-apple ſtove, and there is not room to plunge them in the tan-bed, the plants ſhould be tranſplanted into larger pots in September, that they may be well rooted before they are removed into the ſtove, which ſhould not be till December, or later.

If placed under a frame the beginning of November, to be ſcreened from froſt, it will prepare the plants better for forcing. And where wanted early, a hot-bed ſhould be made under the frames, upon which the plants are put in the latter end of October, by which they are brought forward to flower, and then removed into the ſtove, being placed as near to the glaſſes as poſſible, to have the full influence of the ſun and air; as when placed to the back the plants draw up weak, and the flowers drop without producing fruit.

In the management of the plants in the firſt mode there muſt be care taken to ſupply them with water when they begin to ſhew their flowers, otherwiſe they will fall off without producing fruit; and, in mild weather, freſh air ſhould be admitted to them every day. And in the ſtove method, as the earth in the pots will dry pretty faſt when they ſtand upon the pavement of the hot-houſe, or on ſhelves, they muſt be duly watered; but not too much given at a time, which would hurt them.

Where properly managed, they produce ripe fruit in February, or the beginning of the following month.

When the fruit has been wholly gathered from the plants, they ſhould be put out of the ſtove, and from the borders near the hot wall, that they may not rob the fruit-trees of their nouriſhment and ſupport.

There is another method of ripening this fruit early, which is on hot-beds, where there is not the above conveniences. The plants are prepared in pots in the above manner, and placed in a warm ſituation in the beginning of October; about December the hot-bed is made in the ſame manner as for cucumbers, but not ſo ſtrong; and when the firſt violent ſteam is over, ſome old rotten dung, or, what is better, neat's dung, laid over the hot-bed to keep down the heat. The plants ſhould then be plunged in the pots into the bed, as cloſe together as poſſible, filling up the interſtices between them with earth. They muſt afterwards have air admitted to them every day; and, if the heat of the bed is too great, be raiſed up to prevent their roots being ſcorched. But when too cold, the ſides of it ſhould be lined with ſome hot dung. This bed brings them to flower by the end of February, or the beginning of March, when another mild hot-bed muſt be prepared to receive them. Upon the hot dung ſome neat's dung, about two inches thick, being ſpread equally, to prevent the heat from injuring the roots of the plants, and upon this two inches of a loamy mould; when this has lain two days to warm, the plants ſhould be taken out of the firſt hot-bed and turned carefully out of the pots, preſerving all the earth to their roots, and placed cloſe together upon this new hot-bed, filling up the vacuities between the balls with loamy earth: the roots of the plants ſoon ſtrike out into the freſh earth, which ſtrengthens their flowers, and cauſes the fruit to ſet in plenty; proper care ſhould then be taken to admit freſh air to the plants, and ſupply them perfectly with water, that they may produce ripe fruit in April, or before.

By theſe means a ſucceſſion of this fruit may be obtained from March, April, or even earlier; and in the open air, from June to October and November, ſhould the weather prove mild; for not only the alpine, but the white wood ſtrawberry will continue bearing in tolerable abundance until the autumn froſts come on, eſpecially in warm ſituations, and ſoils not too light.

The heat required in bringing ſtrawberries forward at an early period is ſuch as is ſufficient for forcing the cherry and the peach.

In order to have new varieties of the ſtrawberry, ſeed muſt be employed. To obtain theſe, the ripe berries ſhould be put into a veſſel of water, and the pulp broken and rubbed with the hand, ſo that it may be diffuſed in the water and waſhed completely away, leaving the ſeeds behind. They ſhould then be gradually dried, when they may be ſown in the ſpring on a border of rich, light earth, keeping them watered and free from weeds during the ſummer ſeaſon. See STRAWBERRY.

FRAGILITAS OSSIUM, in *Surgery*, is a very remark-

able diſtemper of the bones, which become ſo brittle as to be broken by exceedingly ſlight cauſes.

The commonly received opinion is, that the fragilitas oſſium ariſes from a deficiency of the animal matter of the bones affected, while the diſeaſe, named *mollities*, is owing to a defective quantity of the lime which naturally enters into the texture of thoſe parts of the body. This idea ſeems to be confirmed by ſeveral inconteſtible facts. Firſt, it is well known, that if we take a recent bone and burn it in a ſtrong fire, all the animal matter will be deſtroyed, leaving the earthy texture alone, which, in this calcined ſtate, is exceedingly brittle. Secondly, every one, at all acquainted with oſteology, is aware that the bones of children have a large proportion of organized animal ſubſtance in their ſtructure, that ſuch young bones are peculiarly flexible, elaſtic, and difficultly broken. Thirdly, in old perſons the earthy part of the bones is very abundant, and the animal matter diminiſhed; conſequently, ſuch bones are much more brittle and eaſily fractured than thoſe of young ſubjects.

From the few remarks already made, it appears that a certain degree of fragilitas oſſium is a natural attendant on old age. However, it is not this ſlighter form of the affection, as ſeen in all old perſons, that we particularly wiſh to treat of in the preſent article. Neither is it our intention to tire the reader with a ſerious refutation of the doctrine, that the bones are always more brittle in froſty weather. The increaſed number of fractures which happen in winter time are fully accounted for by the frequently ſlippery ſtate of the ſtreets and roads at this ſeaſon of the year, and the conſequently greater number of falls.

The diſorder known by the appellation of fragilitas oſſium has been taken notice of by ſeveral authors, and ſome very ſtriking examples of the diſeaſe are recorded. Fabricius Hildanus, in his Cent. 2. mentions an inſtance of a gouty man, ſixty years of age, whoſe bones were ſo brittle that the arm and fore-arm were fractured by the patient endeavouring to put on one of his gloves. The ſame writer alſo, in the ſixty-eighth obſervation of his ſecond Cent. ſpeaks of a woman who broke ſome of her bones in merely trying on a new ſhoe. Nicholas Fontano likewiſe furniſhes us with the hiſtory of a man whoſe bones uſed to break even when handled in a very gentle manner. Rœderer, in a diſſertation, "De Oſſium Vitiis," mentions a woman who died of a ſevere attack of the gout, and all whoſe bones were exceedingly light, brittle, and even friable, "univerſali quaſi carie exeſa, ſimilia oſſium calcinatorum, vel acido quodam liquore imbutorum." Although the middle parts of the cylindrical bones had no appearance of caries, yet they were of a light, looſe, thin texture, which was dry and eaſily crumbled. The metacarpal and metatarſal bones, as well as thoſe of the fingers and toes, were ſo attenuated as to be tranſparent. S. viard and M. Louis cite inſtances of the fragilitas oſſium in perſons who had long laboured under cancerous diſeaſes. The laſt author quotes an example of a nun who broke her arm in ſimply leaning on her ſervant. A patient is deſcribed in the London Medical Journal, who could not turn in bed without breaking ſome bone or another.

The latter ſtage of ſyphilis is ſaid to be ſometimes accompanied with this afflicting diſtemper of the bones. The fragilitas oſſium is alſo ſet down by authors as an occaſional attendant on the ſcurvy.

With regard to the treatment of this peculiar affection little can be ſaid, becauſe, at preſent, little is known. We may ſay, indeed, that when the diſtemper originates independently of any other obvious diſeaſe, no plan of cure is known. Some practitioners have thought that it would be rational to try the effect of the muriatic acid, adminiſtered internally, or of any other acid which has the power of diſſolving the phoſphate of lime. This method appears plauſible, ſuppoſing the theory of the diſeaſe to be correct, and that the brittle ſtate of the bones is owing to the redundance of earth in their texture. However, experience has hitherto exhibited no facts in favour of ſuch treatment. Indeed, doubts may be entertained whether the fragilitas oſſium always depends upon the increaſed quantity of earth, and the diminiſhed proportion of animal matter in the ſtructure of the bones which are affected. The diſeaſe may ſometimes be owing to this alteration of texture; but it appears that the diſtemper called *mollities oſſium*, and which is imputed to a deficiency of lime in the bones, is, at a certain unadvanced period of the diſeaſe, accompanied with the fragilitas. Mr. Gooch has related a caſe which ſhews this circumſtance, and he has adverted to ſome other inſtances of a ſimilar nature. (Chirurgical Works, vol. ii. p. 393. edit. 1792.) The example mentioned by Rœderer, and quoted by us above, was attended with a remarkable lightneſs of the bones, which, therefore, in all probability, did not contain a due proportion of the phoſphate of lime.

When fragilitas oſſium ariſes from any pre-exiſting diſeaſe, ſuch as the ſcurvy, old cancers, &c. it is obvious that if any hopes of relief can be indulged, they can only be realized by curing the primary affection.

FRAGMENS, Fr. anſwers nearly to *Paſticcio*, Italian, in *Muſic*; it is a collection of airs from different ballets, brought together without the leaſt connection, but which, with dancing and ſinging between the acts, ſupply an evening's entertainment as long as a regular opera. The paſticcios of the Italians have been much condemned by opera critics for the liberties taken with the drama, by ſubſtituting airs that have no connection with the recitative; but the fable of a regular drama is ſtill preſerved. The airs in Metaſtaſio's dramas are only recapitulations and illuſtrations of the buſineſs of the preceding ſcene, which would be complete without the air; ſo that if the interpolated air is a good one, and well ſung, it makes ſome amends for its want of connection with the drama. But to put into action fragments of different dramas without any plot to intereſt the audience, ſeems no leſs abſurd than it would be to make the performers of a miſcellaneous concert mount the ſtage, and enact all their ſolos, ſonatas, and concertos; and Rouſſeau truly ſays, that none but a man totally devoid of taſte could have ſuggeſted ſuch a performance, or none but a cold and inſipid audience ſupport it.

FRAGOA DE ST. PEDRO, in *Geography*, a town of Portugal, in the province of Beira; 13 miles S.S.W. of Lamago.

FRAGOAS, a town of Portugal, in Eſtremadura; ſix miles N.W. of Santeren.

FRAGUIER, CLAUDE FRANÇOIS, L'ABBÉ, in *Biography*, born at Paris 1666, was the ſon of a captain in the regiment of guards, deſcended from an ancient noble family. His love for the Greek language rendered him ſo ſtudious, that he acquired in it a knowledge ſo profound as to procure him a place in the Academy of Belles Lettres in 1705, and, in 1707, admiſſion into the French academy. This learned academician was unable to perſuade himſelf that antiquity, ſo enlightened, and ſo ingenious in the cultivation of the fine arts, could have been ignorant of the union of different parts, in their concerts of voices and inſtruments, which he calls "the moſt perfect and ſublime part of muſic;" and thinking that he had happily diſcovered, in a paſſage of Plato, an indubitable and deciſive proof of the ancients having poſſeſſed the art of counterpoint, he drew up his opinion into the form of a memoir, and preſented it to the Academy of Inſcriptions and Belles Lettres, in 1716. M. Burette acquaints us that this abbé learned to play on the harpſichord at an advanced

vanced age, and concluding that the ancients, to whom he generouſly gave all good things, could not do without counterpoint, made them a preſent of that harmony, with which his aged ears were ſo pleaſed.

The paſſage in queſtion is in the ſeventh book of Laws, in which Plato determines that the proper time for young perſons to learn muſic is from thirteen to ſixteen years of age; during which period he ſuppoſed they might be enabled to ſing in uniſon with the lyre, and to diſtinguiſh good muſic from bad; that is, ſuch airs as were grave, decorous, and likely to inſpire virtue, from thoſe that were of a light and vicious caſt. This is ſpeaking like a legiſlator, ſays the abbé Fraguier. But as harmonic compoſition was very bewitching to minds ſo remarkable for ſenſibility as the Greeks, and was, beſides, of ſo difficult a ſtudy, as to require infinite time and labour to accompliſh, he thought it neceſſary to caution them againſt too ſtrong an attachment to it, and therefore eſtabliſhed a kind of rule, by which they would be prevented from giving that time to muſical ſtudies, which might be better employed in more important concerns.

This is but the introduction to the paſſage in queſtion, which is the following: "As to the difference and variety in the accompaniment of the lyre, in which the ſtrings produce one air, while the melody compoſed by the poet produces another, (the poet then ſet his own verſes,) whence reſults the aſſemblage of denſe and rare, of quick and ſlow, acute and grave, as well as of *concord* and *diſcord*. Though the abbé Fraguier tranſlates ἀντιφωνον, *diſſonance*, it is not the true acceptation of the word, nor can it be found thus explained in any lexicon, or Greek writer on muſic; its preciſe and technical meaning will be given farther on. Beſides, the knowing how to adjuſt the rhythm, or meaſure, to all the ſounds of the lyre: theſe are not ſtudies fit for youth, to whom three years only are allowed for learning merely what may be of future uſe to them. Such contrarieties of different difficulties in the ſtudy and practice of muſic, are too embarraſſing, and may render young minds leſs fit for ſciences, which they ought to learn with facility."

It does not ſeem neceſſary here to enter into a verbal criticiſm of this paſſage, as it has been underſtood and tranſlated by the abbé Fraguier; nor to inſert two other paſſages, one from Cicero, and one from Macrobius, which this author has given by way of corollaries, in ſupport of his explanation of the paſſage in Plato; as we ſhall conſign him and his fancied proofs in favour of ancient counterpoint to his brother academician M. Burette, the moſt able writer, in many particulars, of all thoſe who have intereſted themſelves in the diſpute concerning ancient muſic. See BURETTE. The ingenious opponent of the abbé Fraguier proves that the famous paſſage in Plato upon which ſo much ſtreſs has been laid, implies no more than a concert of voices and inſtruments in uniſon and octaves, like plain-chant in the Romiſh church. He proves alſo that Plato determines the word harmony to mean no more than a melody in which the grave and acute ſounds are mixed in ſucceſſion, according to the regulation of the muſical ſcale; and adds that Ariſtotle proves by queſtions in his Problems that the Greeks knew no other harmony, in our ſenſe of the word, than uniſons and octaves, when he aſks: 1. Why a monody (a ſingle voice) is more agreeable than when accompanied by a lyre or a flute, though theſe inſtruments are in tune, and form the ſame ſounds as the voice? 2dly. Why a ſingle inſtrument gives more pleaſure than the union or concert of many inſtruments performing in uniſons and octaves? 3dly. Why are uniſons and octaves the *only accompaniments* that can be ſuffered in concerts, and why are the 4th and 5th, though qualified with the name of perfect concords, excluded?

The abbé Fraguier was not convinced, but as firmly adhered to his original opinion as many others have done, and ſtill do, though ſupported with leſs learning; ſo that their obſtinacy is one degree leſs blameable. It ſeems as if the rooted prejudices of wiſe men were harder to eradicate than thoſe of ignorance and imbecility. It is well known that Fontenelle's attachment to Carteſianiſm was never ſhaken; for after the doctrine of Newton had been eſtabliſhed throughout Europe, he publiſhed his "Théorie des Tourbillons Carteſiens," at the age of near a hundred. The abbé Fraguier died in 1728.

FRAIGHT, or FREIGHT, in *Navigation* and *Commerce*, the hire of a ſhip, or of a part of it, for the conveyance and carriage of goods from one port or place to another; or the ſum agreed on between the owner and the merchant, for the hire and uſe of a veſſel.

The word is formed of the French *fret*, ſignifying the ſame thing; or from *fret*, or *fretum*, an arm of the ſea: though others chuſe to derive it from the German *fracht*, or the Flemiſh *vracht*, ſignifying *carriage*.

The fraight of a veſſel is uſually agreed on either at the rate of ſo much for the voyage, or by the month, or per ton, or other weight, or meaſure. The burthen of the ſhip is generally mentioned in the contract, *e. g.* 300 tons or thereabouts; and the number mentioned ſhould not exceed the exact meaſure above five tons. If a certain ſum be agreed on for the fraight of the ſhip, it muſt all be paid, although the ſhip, when meaſured, ſhould prove leſs, unleſs the burthen be warranted. If the ſhip be fraighted for tranſporting cattle or ſlaves at ſo much a head, and ſome of them die on the paſſage, fraight is only due for ſuch as are delivered alive; if for lading them, it is due for all that are put on board.

The principal laws and rules relating to fraighting are, that if a whole veſſel be hired, and the merchant, or perſon who hires it, do not give it its full load, or burthen, the maſter of the veſſel cannot, without his conſent, take in any other goods, without accounting to him for fraight.

That, though the merchant do not load the full quantity of goods agreed on in the charter-party, yet he ſhall pay the whole fraight; and if he load more, he ſhall pay for the exceſs.

If a time be appointed by charter-party, and either the ſhip be not ready to take in, or the merchant to put on board, the parties are at liberty, with remedy by action for the detriment.

If part be on board, and ſome misfortune prevent the merchant's ſending the whole in time, the maſter may contract with another, and have fraight as damage for the time they were on board longer than limited.

On the other hand, if the veſſel is not ready, the merchant may ſhip the remainder of his goods aboard another, and recover damages againſt the firſt maſter or owners: therefore, by the law marine, chance, or other notorious neceſſity, will excuſe the maſter, but he loſes his fraight till he breaks ground. But if the merchant be in fault, he muſt anſwer the damage, or be liable to maintain the crew ten days; and, if after that, the full fraight; if damage afterwards, it is the merchant's riſk: but by the common law, while the goods are on board, the maſter muſt ſee them forth-coming.

If goods are fully laded, and the ſhip hath broke ground, but the merchant afterward declines the adventure, and unlades again, by the law marine the fraight is due: but if he unload before the ſhip has actually ſailed, he will in ſuch caſe be only reſponſible for damages.

If an embargo be laid on the ſhip before ſhe ſails, the charter-party is diſſolved, and the merchant pays the expence

pence of loading and unloading; but if the embargo be only for a ſhort limited time, the voyage ſhall be performed when it expires; and neither party is liable for damages.

If a ſet time be agreed on between the merchant and maſter, to begin and end the voyage, it may not be altered by the ſupercargo, without ſpecial commiſſion: and if a maſter ſhall ſail on his voyage, after the time agreed on for his departure, and damage happens afterwards, he ſhall make it good. If a ſhip be fraighted from one port to another, thence to a third, &c. and ſo home to the port whence ſhe firſt ſailed (commonly called a trading voyage), the whole is one and the ſame voyage, if performed according to the charter-party. If the ſhip be fraighted out and in, no fraight is due till the voyage is performed; if, therefore, the ſhip periſh coming home, the whole fraight is loſt. If a certain ſum be ſpecified for the homeward voyage, it is due, although the correſpondent abroad have no goods to ſend home.

The maſter may ſet aſhore ſuch goods as he finds in his veſſel, which were not notified to him; or take them at a higher rate than was agreed on for the reſt. But if the maſter fraight his ſhip, and afterwards ſecretly take in other goods, he loſes his fraight; and if any of the fraighter's goods ſhould, for the ſhip's ſafety, be caſt overboard, the reſt ſhall not be ſubject to average, but the maſter muſt make it good. (See AVERAGE.) If the maſter transfer the goods from his own ſhip to another, without neceſſity, and they periſh, he is reſponſible for the full value, and all charges; but if his own ſhip be in imminent danger, the goods may be put on board another ſhip at the riſk of the owner.

If a ſhip be ſtopped or detained in its courſe, either through the maſter's or the merchant's default, the delinquent ſhall be accountable to the other. Thus, if the fraighter load the ſhip with prohibited goods, he ſhall anſwer the fraight contracted: but if the ſhip put into any other port than ſhe is fraighted to, without neceſſity, the maſter ſhall anſwer damage to the merchant; but if forced in by ſtorm, enemy, or pirates, he muſt then ſail to the ſtipulated port at his own coſts.

If the maſter be obliged to refit his veſſel during the voyage, the merchant ſhall wait, or elſe pay the whole fraight: if the veſſel could not be refitted, the maſter is obliged to hire another immediately, otherwiſe only to be paid his fraight in proportion to the part of the voyage performed; though, in caſe the merchant prove that the veſſel, at the time it ſet ſail, was not capable of the voyage, the maſter muſt loſe his fraight, and account for damages to the merchant.

Fraight ſhall be paid for merchandizes which the maſter was obliged to ſell for victuals, or refitting, or other neceſſary occaſions, paying for the goods at the rate the reſt were ſold at, where they were landed.

In caſe of a prohibition of commerce with the country whither the veſſel is bound, ſo that it is obliged to be brought back again, the maſter ſhall only be paid fraight for going.

And if a ſhip be ſtopped or detained in its voyage, by an embargo by order of the prince, there ſhall neither be any fraight paid for the time of the detention, in caſe it be hired per month; nor ſhall the fraight be increaſed, if hired for the voyage; but the pay and the victuals of the ſailors, during the detention, ſhall be deemed average.

The maſter ſhall take no fraight for any goods loſt by ſhipwreck, plundered by pirates, or taken by the enemy, unleſs the ſhip and goods be redeemed; in which caſe he ſhall be paid his fraight to the place where he was taken, upon contributing to the redemption. If part of the goods be thrown overboard, or taken by the enemy, the part delivered pays fraight.

The maſter ſhall be paid his fraight for the goods ſaved from ſhipwreck; and in caſe he cannot get a veſſel to carry them unto the place where they were bound, he ſhall be paid in proportion to the part of the voyage already gone. The ſhip's lading, in conſtruction of law, is tacitly obliged for the fraight; this being, in point of payment, preferred before any other debts to which the goods laden are liable, though ſuch were precedent to the fraight, becauſe the goods remain, as it were, bailed for the ſame.

The maſter may not detain any merchandize in his veſſel, in default of payment of fraight; though he may order them to be ſeized any time, or any where, afterwards. If the goods be damaged without fault of the ſhip or maſter, the owner is not obliged to receive them, and pay the fraight, but he muſt either receive or abandon the whole; he cannot receive thoſe that are not damaged, and reject the others. If the goods be damaged through the inſufficiency of the ſhip, the maſter is liable for the ſame; but if it be owing to ſtreſs of weather, he is not accountable. It is the general cuſtom for maſters, on their arrival, to enter their proteſt, and in caſe, on diſcharge of the ſhip, any damage ſhould appear on the loading, to extend the ſame; but this proteſt muſt be ſupported by evidence of collateral circumſtances.

The maſter is accountable for all the goods received on board by himſelf and mariners, unleſs they periſh by the act of God, or the king's enemies.

The maſter is not liable for carriage of liquors, nor accountable for contents of packages, unleſs packed in their preſence. See INSURANCE.

FRAIGHT is alſo uſed for the burthen, or lading of a ſhip, or the cargo of goods, &c. which ſhe has on board.

FRAIL, in *Rural Economy*, a name ſometimes given to a ſort of flat baſket conſtructed of a ſtrong coarſe ſort of ruſh or flag. It is often likewiſe called a flag baſket.

FRAIL-*baſket*, a term ſignifying the ſame ſort of baſket, and alſo that which is employed in packing up figs, raiſins, &c.

FRAILS, in *Geography*, rocks on the ſouth coaſt of the county of Wexford, in Ireland; 12 miles S.W. from Carnſore point.

FRAIN, or WRANOW, a town of Moravia, in the circle of Znaym, with a citadel; 12 miles W. N. W. of Znaym.

FRAISE, in *Fortification*, a kind of palliſade, or ſtake, placed horizontally in the exterior face of ſuch ramparts as have only half revetements, for the purpoſe of preventing the aſſailants from aſcending. When only one row of fraiſes is uſed, it is uſual to fix them on a level with the terre-plein, *i. e.* on a level with the internal area of the place. Should there be no revetement whatever, a ſecond row of fraiſes will be requiſite, at about nine feet from the bottom of the ditch, ſo as to be above that height to which a man ſtanding on the ſhoulders of another could eaſily climb.

Fraiſes ſhould be about ten feet in length, of which nearly half ſhould be buried in the rampart; otherwiſe they may, when the ſoil is not very firm, or when they are partially decayed, be wrenched out of their places, by means of ropes paſſed over their points. The diſtance between the fraiſes ſhould never exceed five inches, but four are better; and they ſhould be ſupported at every ſix feet by very ſtout poſts let into the rampart, full ſix feet or more, if the ſoil demand it. Two ſtout rails ſhould be laid from one poſt to another, not mortiſing into, but lying upon them, ſo as to overlap. By theſe means they will not be ſo ſubject to rot.

The

The fraiſes ought to be of a triangular form, ſix inches wide on the flat or under ſide which lies upon the rails, and four inches thick between that flat ſide and the angle that lies uppermoſt. After being firmly nailed down in their places, the whole ſhould be ſmeared with tar, which, while hot, ſhould be ſprinkled with ſand paſſed through a fine ſieve; this will cauſe them to reſiſt moiſture, and to remain well coated during the hotteſt weather, provided care be taken to fill up all the chinks at the joints and over-laps in a proper manner.

Fraiſes add conſiderably to the ſecurity of entrenchments, &c. far more than palliſades, which, being erect, offer the chance of muſket balls paſſing through, and are ſubject to be deſtroyed by heavy ſhot; fraiſes are, by their ſituation, ſecure from the ordinary range of artillery, and oppoſe an abrupt obſtacle, ſuch as can be ſurmounted by eſcalade only, an operation attended with imminent danger in every ſituation, but eſpecially where the ladders are, as in this caſe, kept off from contact with the ramparts, ſo as to place the party in a poſition to be flanked, as well as to be oppoſed directly in front.

FRAISED RAILS are now much uſed as defences againſt the encroachments of cattle by gentlemen who object to having ſtanding rails within view of their ſitting rooms, &c. Theſe are placed about two or three feet below the level of the field, in the interior bank of the ditch or hollow in which they are to ſerve as a boundary. In ſuch caſe they ought to have a very ſlight inclination upwards, juſt ſufficient to throw off moiſture. When intended to keep out horſes and horned cattle, they may be made of three rails attached at every eight feet to proper poſts; but, in contradiſtinction to military fraiſes, the rails ought to be fixed beneath, inſtead of reſting upon the rails, as in the former mode they are capable of greater reſiſtance to ſuch animals as might endeavour to force their way. The firſt rail ſhould be placed at ten inches from the bank, and be about four inches ſquare; the ſecond rail ſhould be fifteen inches from the other, centre from centre, and the third rail ſhould be eighteen inches, in like manner, from the ſecond. If ſheep, pigs, &c. are to be kept out, there muſt be a ſet of lath-fraiſes nailed below the rails, each about two inches wide and an inch and a half thick; theſe ought to ſtand at ſix inches from centre to centre, and have their butts within an inch of the bank. They ſhould reſt only on the firſt and ſecond rails generally, having their points projecting about ſix inches beyond the latter; but every third fraiſe ſhould be long enough to paſs over the third or outer rail, and to project its point ſix inches. This is an expenſive, but a very excellent defence, far ſuperior to upright pales; againſt which cattle are very fond of rubbing; they are beſides unſightly and far eaſier to paſs than a fraiſed rail. Where the bank is not ſufficiently ſteep, and it is deſirable to conceal the fence, it ſhould be placed ſomewhat lower down, and make an angle of about 25 or 30 degrees of elevation from the horizon. If the acclivity is great, for inſtance not more than 30 degrees from perpendicular, leſs protruſion may anſwer; therefore the third or outer rail may be omitted; or, if all three be preſerved, they may be laid rather nearer than the diſtances above given. There ſhould be at leaſt two feet of each poſt ſunk in the bank, but three feet will prove far more ſubſtantial.

FRAISING *of a Battalion*, is the lining it all round with pikes, in caſe of being charged by a body of horſe.

FRAIZE, or FRAISE, in *Geography*, a town of France, in the department of the Voſges, and chief place of a canton in the diſtrict of St. Diè, ſix miles S. of St. Diè. The place contains 1678, and the canton 10,088 inhabitants, on a territory of 212½ kiliometres in 10 communes.

FRAMBŒSIA, in *Medicine*, from the French *framboiſe*, a *raſpberry*, a term applied by the noſologiſts to a diſeaſe, endemic in Africa, and thence tranſmitted to the Weſt Indies with the negro ſlaves, and called by them the *yaws*; the term *yaw*, in their language, being ſaid alſo to ſignify a *raſpberry*. Theſe terms have been applied to this contagious diſeaſe, in conſequence of the appearance of elevated fungous tumours, reſembling that fruit, on various parts of the ſkin, forming one of the moſt characteriſtic ſymptoms of the malady. In many other reſpects it reſembles the leproſy of the Jews, as deſcribed in the ſacred writings. See YAWS and LEPROSY. See alſo Sauvages Noſol. Method. Claſs X. Gen. 22, where it is divided into two ſpecies; 1. *Frambæſia Guineenſis*; 2. F. *Americana*. Edin. Medical Eſſays, vol. v. part 2.

FRAMBOISE, a name uſed by ſome for the *rubus* or black-berry-buſh. See RASPBERRY.

FRAME, in *Architecture*, two or more pieces of timber joined together by mortiſe and tenon, ſo as to include a ſpace, the leaſt number of ſtraight pieces that can be joined ſo as to conſtitute a frame being three. Frames in carpentry are generally divided into triangles, and thoſe of joinery into rectangles, as in doors, ſhutters, and wainſcotting.

FRAME is alſo a machine uſed in divers arts. The printers' frame is a ſtand whereon they place the *caſes*, which ſee.

The founders' frame is a kind of ledge, incloſing a board, which being filled with wetted ſand, ſerves as a mould to caſt their work in. See FOUNDERY.

FRAME is more particularly uſed for a ſort of loom, whereon artizans ſtretch their linens, ſilks, ſtuffs, &c. to be embroidered, quilted, or the like.

FRAME, among *Painters*, &c. is a kind of ſquare, compoſed of four long pieces or ſlips of wood joined together; the intermediate ſpace whereof is divided by little ſtrings or threads into a great number of little ſquares, like the meſhes of a net; and for that reaſon ſometimes called *reticula*.

Its uſe is in reducing of figures from great to ſmall, or augmenting their ſize from ſmall to great. See DESIGNING.

FRAME, *Garden*, a ſort of box furniſhed with glaſs covers or lights at top to ſlide, being uſed in gardens for protecting and forwarding tender and early plants of different kinds.

Frames of this ſort are moſtly formed of inch or inch and quarter deal boards, being made of different dimenſions, the largeſt about three yards and a half long, and one and a half wide, as high again or more in the back as in the front, to give the top a due ſlope to the ſun, and proper declivity to carry off the wet, when covered with the glaſs lights occaſionally, as they are wanted in the culture of the plants.

Theſe common kitchen-garden frames may be of three different ſizes, as for one light, two lights, and three lights; the two laſt of which, however, are the moſt material, and employed for general uſes; but it is neceſſary to have one or more one-light and two-light frames, eſpecially in private gardens, the former as a ſeed-frame for a ſmall hot-bed, particularly the ſeeds of cucumbers and melons for the early crops, and other tender plants, and the latter as a nurſery-frame to the young plants of the ſame kinds, &c. to forward them to a due ſize for the three-light frames.

The one-light frame may be about four feet and a half in width, from back to front, and three feet ſix inches the other way; fifteen or eighteen inches high in the back, and

from

from nine to twelve inches high in front, with a glaſs ſaſh or light made to fit the top completely, ſo as to ſlide up and down and remove when neceſſary. And the two-light frame may be ſeven feet long, four and a half wide, and fifteen or eighteen inches high in the back, and from nine to twelve in front, having one croſs bar three inches in width, ranging from the middle of the back at top to that of the front, ſerving both to ſtrengthen the frame and help to ſupport the lights; the two lights to be each three feet ſix wide, made to fit the top of the frame exactly. But a three-light forcing frame ſhould be ten feet ſix inches long, four and a half wide, and from eighteen inches to two feet high in the back, and from nine to twelve and fifteen inches in front; thoſe deſigned principally for the culture of melons being rather deeper than for cucumbers, as they generally require a greater depth of mould or earth on the beds; though frames eighteen or twenty inches in the back, and from nine to twelve in front, are often made to ſerve occaſionally both for cucumbers and melons; each frame ſhould have two croſs bars ranging from the top of the back to that of the front, at three feet ſix inches diſtance to ſtrengthen them and ſupport the lights; the lights ſhould be each three feet ſix inches wide; the whole together being made to fit the top of the frame exactly every way.

They are ſometimes made of larger dimenſions than the above, but they are very inconvenient to move to different parts where they may be wanted, and require more heat to warm the internal air; in reſpect to depth, if they are but juſt deep enough to contain a due depth of mould, and for the plants to have moderate room to grow, they will be better than if deeper, as the plants will be always near the glaſſes, which is an eſſential conſideration in early work, and the internal air be more effectually ſupported in a due ſtate of warmth; as the deeper the frame the leſs the heat of the internal air in proportion; and the plants being further from the glaſſes will be diſadvantaged in their early growth, for which reaſon London kitchen-gardeners have often many of their forcing frames not more than fourteen or fifteen inches high behind, and eight or nine in front, eſpecially thoſe which are intended to winter the more tender young plants, ſuch as cauliflowers, lettuces, &c. and thoſe for raiſing early ſmall ſallad herbs, raddiſhes, and many others.

But when for the protection of taller plants, they ſhould be deeper in proportion. If deſigned as a nurſery-frame for young pine-apple plants, three feet ſix by fifteen or eighteen inches are the proper depth, arranging the largeſt plants behind, the young yearling ones more forward, and the crowns and ſuckers of the year in front of all; a frame of theſe dimenſions may ſerve alſo for any of the hardier kinds of low green-houſe plants, as myrtles, &c. where there is not a proper green-houſe, or as an caſement to it, when too much crowded. It is uſeful alſo as an occaſional winter ſhelter to many ſorts of curious young plants, evergreens, and others of the full grown, which, being tenderiſh in their younger growth, require protection for two, three, or more years, till they increaſe in ſtrength and are gradually hardened to the full air and atmoſphere.

Deep ſorts of frames are ſometimes made uſe of in the culture of particular ſorts of plants, to bring them up to a proper height. See DRAWING *Frame*.

In all ſorts of frames the wood-work of the backs, ends, and fronts ſhould be of ſuch thick deal as has been mentioned, which muſt be all neatly planed even and ſmooth on both ſides, and the joints in framing them together be ſo cloſe that no wet or air can enter; the croſs bars or bearers at the tops for the ſupport of the glaſſes ſhould not be above three inches broad and one thick, and neatly dovetailed in at the back and front even with both edges, that the lights may ſhut down cloſe, each having a groove or channel along the middle to conduct off all wet falling between the lights; at the end of each frame, at top, ſhould be a thin ſlip of board four inches broad, arranged from back to front, joining cloſe up to the outſide of the lights, which is neceſſary to guard againſt cutting winds ruſhing in at that part immediately upon the plants, when the lights are occaſionally tilted behind for the neceſſary admiſſion of freſh air, or other purpoſes. In regard to the lights, the wood-work of the frame of each ſhould be inch and half thick, and two and a half broad; and the bars for the immediate ſupport of the glaſs-work about an inch broad, and not more than inch and half thick, as when too broad and thick they greatly intercept the rays of the ſun. They ſhould only be juſt ſufficient to ſupport the glaſs-work without bending, and be ranged from the back part to the front with exactneſs.

The glaſs-work may either be laid in lead and well trimmed with cement, air and water tight, or in the bars of wood in putty, lapping at the ends; the latter method is by ſome preferred, as being more effectual for the diſcharge of wet, the lapping of the panes being left open or unputtied at bottom, that the rank vapour naturally ariſing in hot-beds, and all condenſed drops againſt the glaſſes, may be diſcharged at theſe places, as well as admit a perpetual moderate current of freſh air, which may be beneficial to the plants; this mode, however, of leaving the lappings open, is by ſome objected to, eſpecially for very early work, on account of the too free admiſſion of air in cold weather.

All the wood-work, both of the frames and lights, ſhould be painted in oil, to preſerve them from decay; a lead colour will be the moſt eligible, and if done three times over, outſide and in, will preſerve the wood exceedingly from the injuries of weather, and from the moiſture of the earth and dung.

Frames for theſe purpoſes are ſometimes made in a ſort of hollow brick-work, ſo as to admit the heat from without. See *Plate on Forcing Frames*.

FRAME-*work*, that ſort of forcing and raiſing vegetable productions at an early period, which is performed by means of frames and artificial heat applied by them. See FORCING.

FRAMERY, NICHOLAS STEPHEN, in *Biography*. This ingenious gentleman is only mentioned by M. Laborde, in his "Eſſais ſur la Muſique," as a French lyric poet, who has furniſhed "Le Theatre Italien" with many ſucceſsful comic operas: adding, "We owe to him "La Colonie," one of the beſt works of its kind, which always fills the heatre, though it has been repreſented perhaps two hundred times." This drama was written in French, and admirably adjuſted to the muſic of Sacchini's Italian comic opera "L'Iſola d'Amore," which was not only the firſt production of that charming compoſer that was heard in France, but the firſt Italian muſic that was ever ſincerely felt in that kingdom. Beſides the favourable account of it by M. Laborde, no enthuſiaſt for Italian compoſition; the late perturbed ſpirit Linguet, ſtill more patriotic in his love of old French muſic, ſpeaking of the comic opera of "La Colonie," in his "Journal Politique et Litteraire" for 1777, ſays: "Among the works that are moſt frequently revived at this theatre, above all others is "La Colonie," which never fails drawing together prodigious crowds. M. Frame-

ry

ry has rendered the public a real ſervice in parodying this Italian opera :" (that is, ſetting new French words to muſic that has been originally ſung to other words, whether Italian or French.) Linguet continues : " He has at once given us a new piece and a new actreſs. It was in " La Colonie" that the talents of Mad. Colombe were firſt developed, whoſe voice, ſo extenſive, ſonorous, and touching, was ſo calculated to produce great effects in pathetic airs ; effects which were ſtill encreaſed by the beauty of her figure. The Colony is perhaps the moſt beautiful Italian muſic which has been heard in our theatres ; no other, at leaſt, has produced ſimilar enthuſiaſm : it is by tears and ſcreams of extacy that many of the airs have gained applauſe ; all the tones, every accent of grief, love and deſpair, ſucceed each other ſo rapidly, as to imitate the emotions of nature, without a ſingle cry of art eſcaping that is diſpleaſing. There is no leſs perfection in the cheerful and playful airs of Sacchini than in the more ſerious. The melody of the whole is exquiſite, nor is it ever ſuffocated by the orcheſtra. Such maſter-pieces as this will form the national ear and taſte, by the beſt of all leſſons, pleaſure."

The taſk which M. Framery undertook, and ſo admirably executed, manifeſted an equal knowledge of poetry and muſic. To make the accents of the French language correſpond with the accents of Italian melody, to the ſatisfaction of his countrymen, ſo tender of their own language, and ſo hoſtile to Italian muſic, was an Herculean labour. But M. Framery, not truſting to conjecture or report concerning the compoſition and performance of Sacchini's muſic, came over into England in 1774, during the regency of Mrs. Yates and Mrs. Brooke, where he found Sacchini, and not only converſed with that elegant and intelligent maſter, but, we believe, ſaw and heard " L'Iſola d'Amore" performed ; and after the ſucceſs of " La Colonie," repreſented in 1775, he went to work on Sacchini's ſerious opera of " L'Olimpiade," which he had heard performed in England, and in 1777, having tranſlated it into French, preſerving the ſame meaſures in the airs, he had it performed at the French theatre Italien, where it was received with enthuſiaſm, though performed by comic actors, unuſed to heroic muſic or poetry. Luckily for the votaries of Italian muſic in France, M. Framery is one of the editors of the Encyclopedie Methodique, in which capacity he manifeſts as much knowledge in the theory, as good taſte in the practice of the muſical art.

FRAMING, in *Gardening*, the art of raiſing different ſorts of tender plants and vegetable productions to perfection at an early period, by the uſe of frames and hot-beds ; or by heat applied in ſome other way, by means of them. Framing is carried on very extenſively in many ſituations, and with a great variety of different kinds of plants, roots, and fruits. It requires much nice care and attention in order to ſucceed in a perfect manner. See FORCING and HOT-*Houſe*.

FRAMING *of a Houſe*, all the timber-work therein, *viz.* the carcaſe, flooring, partitioning, roofing, cieling, beams, aſhlering, &c.

FRAMINGHAM, in *Geography*, a townſhip of America, in Middleſex county, and ſtate of Maſſachuſet's, containing 1625 inhabitants ; incorporated in 1700, and diſtant 24 miles W.S.W. of Boſton.

FRAMLINGHAM, a town of England, in the county of Suffolk, where the princeſs Mary retired before ſhe came to the crown, after the death of her brother Edward VI. It has a weekly market on Saturday. In 1801 the number of inhabitants was 1854, of whom 704 were employed in trade and manufactures ; 88 miles N.N.E. of London.

FRAMPEN, a town of Pomerelia ; 12 miles S. of Dantzic.

FRAMPOLE FENCE, a privilege enjoyed by the tenants of the manor of Writtel, in Eſſex ; whereby they are entitled to the wood growing on the fence ; and as many trees and poles as they can reach from the top of the ditch with the helve of an ax, toward the repair of their fence.

The chief juſtice, Brampton, whilſt ſteward of this court, acknowledged he could not find out the reaſon why theſe fences were called frampole. It may come from the Saxon, *fremfil, profitable ;* or may be a corruption of *franc-pole*, becauſe the poles are free for the tenant to take.

FRANC. See FRANK.

FRANC, GUILLAUME, in *Biography*, ſuppoſed by Bayle (art. Marot,) to have been the firſt who ſet melodies, in a ſingle part only, to the French metrical pſalms of Clement Marot. To this fact Beza himſelf bears teſtimony in a kind of certificate, ſigned with his own hand, and dated Nov. 2, 1552. One of Bayle's correſpondents informs him that he had in his poſſeſſion a copy of the Geneva pſalms, printed in 1564, with the name of Guillaume Franc in the title-page ; and to this edition is prefixed the licence of the magiſtrates, ſigned Gallatin, and ſealed with red wax, declaring Guillaume Franc to be the author of the muſical notes to which the pſalms in that impreſſion were ſet. Some deduction however muſt be made from this account, as ſeveral of the old melodies ſung to the French pſalms of Clement Marot, as well as to thoſe of Sternhold and Hopkins, are known to be German, and to have been previouſly uſed by the Bohemian Brethren, John Huſs, Jerome of Prague, Martin Luther, and perhaps by our priſtine reformer, John Wickliffe. We have long thought that the moſt elegant pſalmodiſts at the time of the reformation, ſuch as Louis Bourgeois, Claude Gondinel, and Claude le Jeune, were not the inventors of the original melodies to the pſalm-tunes ; and it appears from this account of Franc that they only harmonized them in plain counterpoint. See PSALMODY.

FRANCA, in *Botany*, Mich. Gen. t. 22 ; ſee FRANKENIA.

FRANÇAIS, or FRANÇOIS, *Port des*, in *Geography*, ſo called by M. La Pérouſe, a bay, or rather harbour, on the N.W. coaſt of America, ſituated in 58° 37′ N. lat. and 139° 5c′ W. long. from Paris. The variation of the compaſs is 28° towards the E., and the dip of the needle 74°. On the days of the new and full moon, the tide riſes 7½ feet, and it is high water at one o'clock. M. La Pérouſe ſuggeſts that, notwithſtanding ſome inconveniences attending this harbour to thoſe merchantmen who trade for furs on ſpeculation, it has many advantages which recommend it for the eſtabliſhment of a factory ſimilar to that of the Engliſh at Hudſon's bay. Its entrance, rendered difficult by the currents, is ſo narrow, that it might be defended by a ſingle battery of four cannon, placed on the point of the continent. The fort, the magazines, and the whole commercial eſtabliſhment might be erected on " l'iſle de Cenotaphe," which is about a league in circumference, very capable of cultivation, and ſupplied with wood and water. Cargoes might be collected at one point, and thus prevent the delay of ſhips ; and buoys laid down for the interior navigation of the bay would render it very ſafe and eaſy, and pilots might be formed ſo well acquainted with the currents, as to enſure the ſafety of ſhips coming in and going out, and the otter ſkins are ſo plentiful, that

that a greater quantity, as Pérouſe conceives, could not be collected in any other part of America. The climate of this coaſt is much milder than that of Hudſon's bay in the ſame latitude. The pines that grow here were found to meaſure 6 feet in diameter and 140 in height. Vegetation is extremely vigorous during three or four months of the year, and the ſoil ſeems to be well adapted for all common plants. The woods abound with ſtrawberries, raſpberries, and gooſeberries. The rivers are full of trout and ſalmon, and the bay furniſhes various ſorts of flat-fiſh, and alſo of ſhell-fiſh. In the woods were found bears, martens, and ſquirrels, and the Indians ſold bear-ſkins, both black and brown, and thoſe of the ermine, marten, Canadian lynx, ſquirrel, beaver, mountain rat of Canada, red fox, &c.: but the valuable, and in this place the moſt common ſkins, are thoſe of the ſea-otter, ſea-wolf, and ſea-bear. Although the different ſpecies of birds are not numerous, yet individuals of each are plentiful; even the copſes were full of linnets, nightingales, blackbirds, and water-quails, whoſe ſongs were very agreeable. The primary mountains of granite, or of ſchiſt, covered with eternal ſnows, where no trees nor plants are ſeen, have their baſes in the water, and form a kind of quay along the ſhore. Their ſides are ſo ſteep that wild goats cannot climb beyond the firſt two or three hundred toiſes; and all the ſtreams by which they are divided are converted into immenſe glaciers, whoſe ſummits riſe beyond the reach of ſight, while their baſes are waſhed by the ſea; and at the diſtance of a cable's length from ſhore the water cannot be ſounded with a line of 60 fathoms. The ſides of the harbour are formed of mountains of the ſecond order, eight or nine hundred toiſes high, decorated with pines and verdure, and only covered with ſnow on their ſummits. They ſeemed entirely compoſed of ſchiſt in the commencement of its decompoſition, and though difficult of aſcent, are not quite inacceſſible. The conſtitution and manners of the inhabitants are adapted to the rough and uncultivated ſtate of the ſoil; and waging continual war with every kind of animal, they deſpiſe the vegetable productions that ſpring up around them. Although the arts of life are here conſiderably advanced, and they have made conſiderable progreſs towards civilization, yet that kind of civilization which poliſhes manners and ſoftens ferocity is yet in its infancy; for their mode of life, excluding all ſubordination, expoſes them to be continually agitated by fear or vengeance, and being choleric and prone to violence, they inceſſantly raiſe their poignards againſt one another. Subject to famine in the winter, they enjoy in ſummer the moſt profuſe abundance; for in leſs than an hour they catch fiſh enough for the ſubſiſtence of their families during the day. The reſt of their time is conſumed in idleneſs, or devoted to play, which they purſue with as much ardour of paſſion as the diſſipated inhabitants of a great metropolis, and, like them, they make it the grand inexhauſtible ſource of quarrels. The ſhips of the French navigators were continually ſurrounded by canoes of Indians, who, after a lapſe of three or four hours, would commence an exchange of a few fiſh, or two or three otter-ſkins, ſeize every opportunity of plunder, ſteal every piece of iron that could be carried away, and in the night time, by every means of eluding vigilance, whilſt the principal perſons among them were loaded with preſents, they were never aſhamed of ſtealing a nail or an old rag of cloaths. Theſe people ſeemed to be always quarrelling among themſelves; were indifferent to their children, and tyrants to their wives, whom they condemned to inceſſant and intolerable labour. The navigators never landed without being armed and in a body, for the people greatly dreaded their muſkets; and eight o ten Europeans together might command a whole village. This village conſiſted of three or four pent-houſes, 25 feet long, and 15 or 20 broad, covered only to windward with planks or bark of trees, in the middle of which were ſuſpended ſalmon and other fiſh to dry in the ſmoke. Eighteen or twenty perſons lodged in each of theſe pent-houſes; the women and children on one ſide, and the men on the other. Each cabin appeared to conſtitute a tribe independent of its neighbours, which poſſeſſed each a boat and a ſort of chief, and left the bay, carrying with them their fiſh and wood, whilſt the reſt of the village took no part in their proceedings. This port ſeems to be inhabited only during ſummer; for there was not a ſingle cabin ſheltered from rain, and though there were not at any time more than 300 Indians together in the bay, our navigators were viſited by 7 or 800 others. In their canoes they carried their houſes and furniture, conſiſting of ſeveral little cheſts, containing their moſt valuable effects. Theſe cheſts were placed at the entrance of their cabins, which are more filthy and noiſome than the dens of the moſt loathſome animals. Every thing about them bears the appearance of dirt and filth, indolence and lazineſs. The wooden veſſels in which they cook their fiſh are never waſhed, but ſerve equally for kettle, diſh, and plate; and as they cannot be placed on the fire, they boil their water by throwing in red hot flints, continually renewing them till their food is completely dreſſed. The dog being the only animal with which they ſeem to have made any alliance, there are commonly two or three of theſe in each cabin. The men pierce the cartilage of their noſe and ears, and attach to them various ornaments. They ſcarify their breaſts and arms with a ſharp iron inſtrument, whetting it upon their teeth as on a ſtone. Their teeth are filed down even with the gum; their faces and other parts of their bodies are painted in a frightful manner, with ochre, lamp-black, and black-lead, mixed up with the oil of the ſea-wolf. During their chief ceremonies, their hair is long, powdered, and dreſſed with the down of various ſea-birds, which they count their greateſt luxury. A plain ſkin covers their ſhoulders, whilſt the reſt of the body is left naked. They have great varieties of head-dreſſes, which were formed to render them more frightful, and probably to inſpire their enemies with terror. Some of the Indians had entire ſhirts of otter-ſkins, and the ordinary dreſs of the grand chief was a ſhirt made of the elk-ſkin. The arms of the women only are tattooed; and each of them has the lower lip cut acroſs even with the gums through the whole width of the mouth; and in this inciſion they wear a kind of ladle without handles, which preſſes againſt their gums, to which their cut lip ſerves as a pad outwards, ſo that the lower part of the mouth projects two or three inches. Theſe women, however, the moſt diſguſting on earth, covered with fœtid, and frequently untanned ſkins, excited deſires and careſſes, which, after ſome reluctance, they freely indulged. Theſe people ſeemed to have neither temple nor prieſts, nor any kind of religion. In ſize and figure they differ very little from Europeans; their features are round, but their eyes never communicate one tender ſentiment. The colour of their ſkin is brown, being tanned by conſtant expoſure to the ſun, as their children are born white. They have leſs beard than Europeans, but enough to refute the error that the Americans are deſtitute of beards. Their bodily frame is feeble; ſome of them indicated ſymptoms of ſcurvy; and they arrive at no great age. M. La Pérouſe is of opinion that theſe people are not *Eſquimaux* (which ſee); but that they have a common origin with all the inhabitants of the interior of Canada, and the northern parts of America. Theſe Indians have made much greater pro-

greſs

greſs in the arts than in morals, and their induſtry is more advanced than that of the inhabitants of the South ſea iſlands, agriculture excepted. They are acquainted with the method of forging iron and moulding copper. They ſpin the hair of various animals, and, with a needle, form of that wool a manufacture ſimilar to our tapeſtry. With this web they mingle ſtrips of the otter-ſkins, which gives to their cloaks a reſemblance of the fineſt ſilk-ſhag. They are peculiarly ſkilful in the manufacture of ſtraw hats and baſkets; and they ſculpture men and animals in wood and ſtone. They decorate boxes of an elegant form with ſhell-work, and cut the ſerpentine ſtone into jewels, to which they give the poliſh of marble. Their arms conſiſt of the poignard, a lance of wood hardened in the fire, or of iron, and a bow and arrows uſually pointed with copper. Seven large canoes, found wrecked at the mouth of the harbour, led M. la Pérouſe to conclude that Port de Français was an emporium, inhabited only during the fiſhing ſeaſon; and he thinks it poſſible that the Eſquimaux, in the vicinity of the Shumagin iſlands, and of the peninſula explored by captain Cook, might extend their commerce to this part of America, furniſhing it with iron, and other articles, and taking, with great advantage to themſelves, the otter-ſkins which they ſo eagerly deſire.

The language of this people, ſays M. de Lamanon, who particularly examined it, manifeſts no reſemblance to that of Alaſka, Norton ſound, Nootka, Greenland, or the Eſquimaux, Mexicans, Nadoeſſis, and Chipawas, whoſe vocabularies he collected. Nevertheleſs there ought to be a great affinity of ſound between this language and that of the entrance of Nootka ſound, for K is the predominant letter in each, and occurs in almoſt every word. Their initial conſonants and terminations are very often the ſame; and it is not perhaps impoſſible that this language may have a common origin with that of Mexico: but if this be the caſe, the origin muſt be very ancient, ſince their words have no reſemblance, except in their elements, but not in their ſignification.

No trace of cannibaliſm was perceived among theſe people, though it is ſo general a cuſtom among the Indians of America; but poſſibly it might have been otherwiſe, if they had been at war, or had taken any priſoners, during the ſtay of our navigators among them. La Pérouſe's Voyage, vol. i.

FRANCAISE, La, a town of France, in the department of the Lot, and chief place of a canton, in the diſtrict of Montauban; 7 miles N.W. of Montauban. The place contains 3,203, and the canton 5,808 inhabitants, on a territory of 145 kiliometres, in 5 communes. N. lat. 44° 7′. E. long. 1° 20′.

FRANCAVILLA, a town of Naples, in the province of Otranto. It is large and well built, the ſtreets are wide and ſtraight, and the houſes ſhewy, though in a heavy ſtyle of architecture. In 1734, a conſiderable part of the town was deſtroyed by an earthquake; and ſince that time the inhabitants have erected their houſes to the height of no more than one ſtory above the ground-floor. The avenues to the gates are well planted with trees, which afford an agreeable ſhade. The inhabitants, about 12,000 in number, ſubſiſt by the ſale of oil and cotton, of which laſt they make very fine ſtockings. The tobacco, which is raiſed in conſiderable quantity in the vicinity, is manufactured into a kind of ſnuff, reſembling the Spaniſh in colour and flavour. This town derived its name Francavilla, or Fair town, from a colony planted here in 1310, by Philip of Anjou, prince of Taranto, who granted lands to all comers, with ten years' exemption from taxes, and gave it an olive-tree, the emblem of peace and fertility, for its armorial ſeal. The manſion of the prince is a quadrangular caſtle, ſurrounded by a dry ditch. About the middle of the ſixth century, this and the adjoining manors were purchaſed by the Imperials of Genoa, from St. Charles Borromeo, archbiſhop of Milan, who is ſaid to have diſtributed in one day the whole purchaſe-money to the poor of his dioceſe, afflicted at that time with peſtilence and famine; 15 miles E.N.E. of Taranto.—Alſo, a town of Naples, in the Baſilicata; 11 miles S.W. of Turſi.—Alſo, a town of Naples, in Calabria Ultra; 13 miles W.S.W. of Squillace.—Alſo, a town of Naples, in Calabria Citra; 4 miles N.E. of Caſſano.—Alſo, a town of Naples, in Abruzzo Citra; 9 miles N.E. of Civita di Chieti.—Alſo, a town of Sicily, in the valley of Demona; 12 miles W.N.W. of Taormina.—Alſo, a town of Genoa; 6 miles S. of Novi.

FRANCE, in *Geography* and *Hiſtory*, is ſituated between the fifth degree of longitude weſt, and the eighth degree of longitude eaſt, from Greenwich; or, according to the French calculation, between the thirteenth and twenty-fifth degrees of longitude by the meridian of the iſland of Ferro, and between the forty-ſecond and fifty-ſecond degrees of northern latitude.

From north to ſouth, or from the Maes and the Wale to the frontiers of Catalonia in Spain, its extent is 300 leagues in length; and from eaſt to weſt, or from Straſburgh to Breſt, 250 leagues in breadth. According to Mr. Necker, the whole extent of France, without the iſland of Corſica, was, in the year 1789, computed at 26,950 ſquare leagues, 25 to a degree. The committee of the firſt national aſſembly ſtated it ſoon after at 26,463 ſquare leagues. The preſent extent of France, including the iſland of Corſica, but without Genoa, Tuſcany, and the Papal dominions, lately added to the French empire, is computed at 762,625 ſquare kiliometres, or 30,505 ſquare leagues.

The boundaries of France are, on the north ſide, the Engliſh Channel and the kingdom of Holland; on the north-eaſt ſide, the Rhine, by which it is ſeparated from Germany, or the ſtates forming the new Confederation of the Rhine; on the eaſt ſide, that chain of mountains called the Jura, which ſeparates France from Switzerland; on the ſouth-eaſt ſide, the Alps, by which it is ſeparated from the kingdom of Italy; on the ſouth ſide, the Mediterranean ſea, and that chain of mountains called the Pyrenees, by which it is ſeparated from Spain; and on the weſt ſide, the Atlantic ocean.

France, which by the Romans was denominated Tranſalpine Gaul, or Gaul beyond the Alps, to diſtinguiſh it from Ciſalpine Gaul, on the Italian ſide of the Alps, was probably peopled originally from Italy, to which it lies contiguous. Like other European nations, it ſoon became a deſirable object to the ambitious Romans, and was, about half a century before the Chriſtian era, annexed to their vaſt empire. In their poſſeſſion it continued till the downfall of the empire, when it was ſubdued by the Franks, from whom it received the name of France. Theſe Franks were originally tribes of Germans, who inhabited the diſtricts on the Lower Rhine and Weſer. They aſſumed the honourable name of Franks, or freemen, from a temporary union among themſelves to reſiſt the power of Rome. See Franks.

The hiſtory of few countries is better aſcertained, or more to be relied on, than that of France, from the commencement of the reign of Clovis, A.D. 481. At this period, or very ſhortly after, Clovis (to whoſe article the reader is referred for information peculiar to himſelf) poſſeſſed all the country lying between the Rhine and the Loire, which, though a very extenſive dominion, was nevertheleſs conſiderably

ſiderably leſs than what it now is, as we have above deſcribed its boundaries. One of his firſt acts, after his marriage with Clotilda, daughter of the duke of Burgundy, was to ſeize upon that prince's dominions; the duke himſelf being glad to retire into private life. By his wife he was converted to Chriſtianity, but his zeal for religion had no effect in reſtraining the bounds of his ambition. He employed the remainder of his life in the aggrandizement of himſelf, and in extending his dominions, without any regard to the means by which he could accompliſh his projects. In his attacks on Armorica [Bretagne], he did not prove ſucceſsful; and, as we have ſeen, this part of the country was not united to the crown of France till the cloſe of the fifteenth century. (See ARMORICA.) The ſucceſsful oppoſition introduced an equal and honourable union: the Franks eſteemed the valour of the Armoricans, and the Armoricans were reconciled to the religion of the Franks. The king now turned his attention to the reduction of the northern provinces, which, inſtead of being decided by the chance of a ſingle battle, appears to have been ſlowly effected by the gradual operation of war and treaties; and Clovis acquired each object of his ambition by ſuch efforts as were fully adequate to its real value. "His ſavage character," ſays Mr. Gibbon, "and the virtues of Henry IV. ſuggeſt the moſt oppoſite ideas of human nature; yet ſome reſemblance may be found in the ſituation of the two princes who conquered France, by their valour, their policy, and the merits of a ſeaſonable converſion." The Burgundians, at this time, poſſeſſed all the country from the foreſt of Voſges to the ſea of Marſeilles on the one ſide, and to the Alps on the other. This vaſt tract of country Clovis attempted to ſubdue; but, after all his efforts, he was obliged to give up the enterpriſe, and reſt for the preſent contented with forming an alliance with, and accepting military ſervice of, the king of Burgundy. The next expedition of Clovis was againſt the Viſigoths, whoſe territories extended to conſiderable diſtances on each ſide of the Pyrenean mountains, under the pretence of contending with the errors of Arianiſm. Alaric, the king of the Viſigoths, a young man deſtitute of military experience, though very brave, determined to contend for his country and the altars of his people. His army was defeated, himſelf ſlain, and Clovis was enabled, as the reſult of this victory, to eſtabliſh himſelf in winter-quarters at Bourdeaux. Toulouſe ſurrendered the next ſpring, and the royal treaſures of the Viſigoths were tranſported to Paris. Other conſiderable places fell into the hands of Clovis, who was ſoon after ſtopped in his career of victory by Theodoric, king of the Oſtrogoths, who had overturned the dominion of Odoacer in Italy. About the year 509, Clovis aſſumed the title of Roman conſul, by which the people of Rome were inſenſibly led to pay peculiar regard to the French monarchs; and the king was now ſuppoſed to be inveſted with a juſt title to all his conqueſts, in whatever manner they had been acquired. He was ſolemnly inveſted with his new dignity in the church of St. Martin, in the city of Tours; after which, he entered the cathedral cloathed in all the badges of office. Clovis, as we have ſeen in his article, died in 511; and his vaſt dominions were divided among his four ſons, who were perpetually at war with each other. A ſeries of weak and wicked princes ſucceeded, under whom France was reduced to more than its ancient barbariſm. The whole power of the kingdom was inveſted in the captains of the king's guard, who were commonly called "Maires du Pálais," and who, for many generations, held the French ſovereigns in abſolute ſubjection, leaving them but little more than the title of king. Of theſe mayors, Pepin and Charles Martel are the moſt celebrated. The latter bequeathed the government of France to his two ſons, Pepin the younger and Carloman; and, on the reſignation of the latter, Pepin ſucceeded to the ſole adminiſtration: and in this exalted ſtation he acquitted himſelf ſo well, as to render his name illuſtrious to ſubſequent generations. When he had ſubdued his foes, both foreign and domeſtic, he determined to aſſume the title of king, after having ſo long enjoyed the regal power; and his deſire, in this reſpect, ſeemed to correſpond with the unanimous wiſhes of the nation. The nobility were, however, bound by an oath of allegiance to Childeric, the nominal monarch at that time; and this oath they could not diſpenſe with but by the authority of the pope. Ambaſſadors were accordingly diſpatched from the nobility and Pepin to pope Zachary, the reigning pontiff. His holineſs replied, that it was lawful to transfer the regal dignity from hands incapable of maintaining it, to thoſe who had ſucceſsfully preſerved it, and that the nation might unite in the ſame perſon the authority and title of king. On this Pepin was crowned in 751, and was the firſt monarch of the ſecond race of French ſovereigns; having driven from the throne of his anceſtors Childeric III. whom he confined for the remainder of life in different monaſteries, and ſet aſide the line of Clovis.

The attention of Pepin was firſt claimed by the revolt of the Saxons; but they were ſoon reduced to ſubjection, and obliged to pay an additional tribute. The ſubmiſſion of the Saxons was followed by the reduction of Britanny, and this again by the recovery of Narbonne from the infidels. His next exploit was the protection of pope Stephen III. againſt Aſtolphus the king of the Lombards. The pope, unable to contend with ſuch a powerful rival, croſſed the Alps to implore the aid and protection of Pepin, who received him with all the reſpect due to his character. He was lodged in the abbey of St. Dennis, and attended by the king in perſon, during a dangerous illneſs. On his recovery, Stephen ſolemnly placed the diadem on the head of his benefactor, beſtowed the regal unction on his two ſons Charles and Carloman, and conferred on the three princes the title of "Patrician of Rome." Pepin was not deficient in duty and reſpect; in return for theſe high honours he accompanied the pontiff into Italy at the head of a powerful army, and reduced Aſtolphus to obedience. Scarcely, however, had Pepin left the country, when Aſtolphus broke the treaty which he had been forced to ſign with every mark of ſolemnity. The pope was again reduced to diſtreſs, and again applied to Pepin for ſuccour, which he received moſt readily. After this Aquitaine was once more annexed to the crown of France; but Pepin had ſcarcely time to indulge himſelf with a view of his new conqueſt when he was ſeized with a ſlow fever, which put an end to his life in the year 768.

Pepin was ſucceeded in his authority by his two ſons, Charles and Carloman; the latter very ſoon died, and left Charles ſole maſter of France, whoſe conduct and actions were ſo brilliant that he juſtly obtained the title of the Great, or CHARLEMAGNE, which ſee. This prince took poſſeſſion of Lombardy in Italy, carried on a war with the Saxons, and brought the whole of Germany under his dominion. He likewiſe took a great part of Spain from the Saracens, and was ſo much feared in the Eaſt, that the king of Perſia ſent him preſents, gave him a title to Jeruſalem, and the Holy Land, calling him his lieutenant, and he was at length proclaimed emperor, in the year 800. It may be worthy of obſervation that Pepin had introduced the ſyſtem of annual parliaments, in which the clergy and nobles were called on to deliberate on public affairs, and the wants of

the

the people. Charlemagne carried this meaſure one ſtep farther; he appointed theſe aſſemblies to be held twice a year, to which he invited the people as a party, by admitting from each province twelve deputies. The aſſembly now conſiſted of three eſtates, each forming a ſeparate chamber, that diſcuſſed apart the concerns of its own order, and afterwards united to communicate their reſolutions, or to deliberate on their common intereſts. The empire of Charlemagne, raiſed and ſupported ſolely by his authority and great talents, fell to pieces under his poſterity. His ſurviving legitimate ſon Lewis (Le Debonnaire) was conſecrated emperor and king: and as almoſt the firſt act of his reign, he divided the kingdom among his ſons, who were perpetually engaged in violent quarrels with one another, and who ſeemed to agree in no one thing but in a joint hoſtility to their father, in which they were ſupported by pope Gregory IV. At length Lewis was compelled to ſurrender himſelf priſoner to his own children, and finiſhed an inglorious reign in the year 840. The diſſentions of the brothers ſtill continued. Lotharius, now emperor, and Pepin, his brother's ſon, took up arms againſt the two other ſons of Lewis le Debonnaire, Lewis of Bavaria and Charles the Bald, and were defeated by them in a pitched battle, in which it is ſaid 100,000 were left in the field. Lotharius was at firſt depoſed by an aſſembly of biſhops, but ſoon ſo far aſſuaged the reſentment of his enemies as to become a party in a new partition of the empire. By this the weſtern part of France was aſſigned to Charles the Bald. Lotharius, with the title of emperor, had the nominal ſovereignty of Italy, and the real territory of Lorraine, Franche Compte, Provence, and the Lyonnois: the kingdom of Germany fell to the ſhare of Lewis, who was hence denominated Lewis the German. By this partition, Germany and France were ſo disjoined, as never afterwards to be united under one head. From the year 845 the provinces were much haraſſed by the inroads of the Normans, till at length leave was granted to them to ſettle in Frieſland. During the reign of Charles the Gros theſe piratical invaders failed up the Seine with a fleet of 700 ſhips and laid ſiege to Paris. They were induced to abandon their undertaking by the bribe of a very large ſum of money, and not by the power of the exiſting government. The money not being readily raiſed, they were allowed to remain in the neighbourhood of Paris during the winter; and they requited this indulgence by plundering the country, and amaſſing immenſe wealth, independently of the ſum which had been promiſed by the king. After this ignominious tranſaction Charles returned to Germany, where he was ſo far abandoned by his friends, as not only to be depoſed, but reduced likewiſe to a ſtate of abſolute penury, and muſt literally have ſtarved but for the charitable aid of the archbiſhop of Mentz. On the depoſition of this abject prince, Eudes, count of Paris, was choſen king during the minority of Charles, afterwards ſtyled "Charles the Simple." He defeated the Normans and repreſſed the power of the nobility, which occaſioned ſo much oppoſition that he was obliged to reſign the crown, and the greater part of the kingdom to the young prince, and conſented to do him homage for that part which he ſtill held as ſovereign. Shortly after this Eudes died, and Charles ſucceeded to the whole power. During his reign the French government declined. By the introduction of fiefs thoſe noblemen who had got poſſeſſion of governments, having theſe confirmed to them and their heirs for ever, became, in a manner, independent ſovereigns: and as theſe great lords had others under them, and they again had others under them, and even theſe had their vaſſals; inſtead of the ſimple and equal government that prevailed before, a vaſt number of inſupportable little tyrannies was erected. The Normans, too, ravaged the country in the moſt terrible manner, and deſolated ſome of the fineſt provinces of France.

At length, in the year 912, Rollo, a chief of the Normans, compelled Charles the Simple to yield him a large portion of his territory, and to give him his daughter in marriage. The new kingdom was called Normandy, of which Rouen was the capital. Rollo, on this occaſion, became a Chriſtian, and changed his own name to Robert, in the ceremony of inveſtiture. Rollo rejected with diſdain the ſervile indignity of proſtrating himſelf before and kiſſing the feet of the ſovereign, and one of his guards was accepted as his ſubſtitute; the rude Norman, unpractiſed in the arts of courts, handled the royal foot ſo rudely, as nearly to overturn the chair, and endanger the ſafety of Charles. In this reign the imperial dignity was transferred from France to Germany. During the remainder of the reign of Charles the Simple, and the next three or four reigns, the power of the Carlovingian race continually declined: no great man roſe up among them to redeem the character of the monarchy, and to inſpire the people with new vigour, and at laſt they were completely ſupplanted by Hugh Capet, who was already, by creation, a prince of France. This revolution happened in the year 987, and was brought about in the ſame manner as the former one had been by Pepin. He was acknowledged at Rheims, A. D. 988. The character of Hugh Capet was not marked with any of thoſe commanding features which generally diſtinguiſh the founder of a new dynaſty; but his policy, his talents and moderation, were well adapted to the times in which he lived. Under him Paris became the ſeat of government, and to prevent the incurſions of the Normans, he fortified ſeveral advantageous ſtations, and eſtabliſhed a magazine of arms at Abbeville. The greater part of his reign was paſſed in ſtrict tranquillity, and he died in October 997, having been on the throne ten years, leaving his crown to his ſon Robert.

The new king inherited the good qualities of his father, and in his reign the kingdom was enlarged by the death of Henry, duke of Burgundy, to whom he was the natural heir. This acceſſion of territory was not obtained without a war of ſeveral years continuance, on account of ſome perſons who laid pretence to a ſuperior right. As Robert thought peace and tranquillity were preferable to widely extended dominions, with a precarious tenure, he refuſed the kingdom of Italy, and the imperial crown of Germany, both which were offered him. His own prudence, juſtice, and moderation, contributed greatly to ſecure the public happineſs, which had ſo honourably diſtinguiſhed his adminiſtration; and at his death, which happened in July, 1030, his ſubjects exclaimed, as with one voice, "we have loſt a father who governed us in peace; beneath whoſe authority we dwelt in ſecurity; who ſuffered not in others that oppreſſion which he himſelf diſdained; who commanded our affections, and who baniſhed our fears." Paſſing over ſeveral reigns, in which there is nothing very remarkable to diſtinguiſh them, we come to Philip I., who is celebrated for having undertaken an expedition to the Holy Land. This expedition, known by the name of the Cruſades, Philip and his adherents were urged to make by Peter the Hermit. Both clergy and laity impreſſed on their garments the ſign of the croſs, and ſolicited the pope to march at their head. This dangerous honour the prudent ſucceſſor of St. Peter declined, recommending, however, to the faithful, who were diſqualified by ſex or profeſſion, by age or infirmity, to aid with their prayers and alms the perſonal ſervices of their more robuſt brethren. After confeſſion and abſolution the champions of the croſs were diſmiſſed, and their departure

for

for the Holy Land was fixed for the feſtival of the aſſumption, the 15th of Auguſt 1096. That day was anticipated by a thoughtleſs crowd, who to the number of ſixty thouſand perſons of both ſexes preſſed with clamorous importunity Peter the Hermit to lead them to the holy ſepulchre. The hermit, aſſuming the character without the talents or authority of a general, impelled or obeyed the forward impulſe of his votaries along the banks of the Danube and the Rhine. The footſteps of Peter were followed by the monk Godeſcal, whoſe ſermons had ſwept away 20,000 peaſants from the villages of Germany. The rear was cloſed with two hundred thouſand of the refuſe of the people, who mingled with their devotion a brutal licenſe of rapine, proſtitution, and drunkenneſs. Of this vaſt crowd, the greater part ſunk beneath the fatigues of their march and the accumulated preſſure of hunger and thirſt: the remainder, who had endured and ſurmounted the difficulties and diſtreſs of their long and tedious pilgrimage, had ſcarcely refreſhed their waſted bodies with the hoſpitable plenty of Conſtantinople, before their impatience urged them headlong, as it were, againſt the Turks. This imprudence betrayed them into the ſnares of the ſultan of Nice; and Peter the Hermit, ſecurely ſheltered in the Byzantine court, might lament the fate of his improvident companions, and expect the arrival of their more grave and noble brethren. Among theſe, the firſt rank both in war and council was juſtly due to Godfrey of Bouillon, who in the hour of victory was elevated to the tranſient throne of Jeruſalem. With him were joined in the holy enterprize Hugh, count of Vermandois, the brother of the king of France, and Robert duke of Normandy, who for the trifling ſum of ten thouſand marks mortgaged Normandy, during his abſence, to Rufus, who had already defrauded him of the crown of England. (See CROISADE.) It was at the diſtance of nearly a century from this time that Philip II. in conjunction with king Richard of England, unfurled the ſacred banner of the croſs, and embarked, the former at Genoa, and the latter at Marſeilles; but animoſities ariſing between them, Philip returned and poſſeſſed himſelf of ſeveral provinces in France that belonged to the Engliſh. Philip died in 1223, and was ſucceeded by his ſon Lewis VIII. who reigned three years, when by death he made way for Lewis IX. afterwards ſtyled Saint Lewis. In theſe and ſome other following reigns the war was carried on with vigour againſt the infidels, but in this ſketch it is impoſſible to do more than notice the various revolutions that have occured in the country, and the circumſtances which are ſuppoſed to have given riſe, or at leaſt very much contributed to them. One of the moſt remarkable tranſactions that took place at the cloſe of the fourteenth century, was the expulſion and confiſcation of the eſtates of the Knights Templars, who at that period enjoyed immenſe poſſeſſions in France. Theſe confiſcations were levied, according to the ſpirit and practice of the times, without any form of trial, and upwards of fifty of them were put to death in the moſt cruel manner. The grand maſter, with three of the principal officers, were burnt by ſlow fire in the preſence of the king himſelf. The whole body of the knights had been accuſed of the moſt immoral practices, of which, indeed, confeſſions had been extorted, but it was aſſerted that the horror of impending and cruel deaths had forced from their lips confeſſions which they afterwards retracted; and it has been generally thought that king Philip, in theſe ſevere and brutal meaſures, conſulted his avarice rather than his juſtice. He died in 1395, and his ſucceſſor, Lewis the Boiſterous, followed him in a few months to his grave, leaving the throne to Philip the Long, who ſubdued the Flemings, and ſummoned Edward II. of England to do him homage for his poſſeſſions in France; but that monarch, finding himſelf involved in difficulties which rendered a journey to France highly inconvenient, ſent excuſes to Philip which he readily accepted. As the French ſovereign had formerly taken the croſs during the life-time of his father, he now propoſed to put his vow into execution, but was diſſuaded from it by the pope himſelf, at whoſe inſtance he ſent an army into Italy to put an end to the contending factions of the Guelphs and Gibbelines, who for ſo long a time filled the country with blood and ſlaughter. The event proved highly unfortunate, and the diſgrace was rendered more mortifying by a contagious diſtemper which ſwept off many thouſands of the French ſoldiery. This fatality in the army was imputed to the Jews, who were ſuppoſed to have poiſoned the ſprings: a perſecution was inſtantly commenced againſt theſe unfortunate men, and numbers, without any other pretence than the madneſs of popular ſuſpicions, were burnt alive; while the Jews in general were abandoned to the rage of the populace, who inſulted their perſons and plundered their houſes without remorſe. The remaining part of this reign was ſpent in attempting to regulate the internal concerns of the country. A deſign had been formed by his predeceſſors of eſtabliſhing a certain ſtandard for the coin, weights, and meaſures, throughout France; this was adopted by Philip, who, in order to carry it more effectually into execution, purchaſed from the counts of Valois, Clermont, and Bourbon, their right of coinage within their own dominions; but notwithſtanding all his endeavours, he never could bring the ſcheme to bear. He was embarraſſed by new and unexpected difficulties: a report was induſtriouſly circulated, that to ſurmount theſe he intended to levy a fifth on every man's eſtate, and the public diſcontent was increaſed by the diſaffection of the clergy, whom the king by a law had excluded from ſitting in parliament. The mind of Philip was too ſenſibly wounded by the injurious ſuſpicions of his ſubjects; he beheld his honeſt endeavours productive of jealouſy and diſappointment, which he was unable to bear, and he died in the year 1322. His ſucceſſor, Charles IV., was the laſt of the royal race of Capet: the character of this prince was not diſtinguiſhed by any very eminent virtues, nor ſtained by groſs vices; his regard to juſtice was ſteady and impartial, of which there are inſtances on record. He died in 1328, leaving his queen pregnant; and as the ſucceſſion depended on the event, a regent in the mean time was neceſſary. Two candidates inſtantly appeared for this important poſt, urging at the ſame time their right to the crown as well as the regency. Theſe were Philip de Valois, couſin to the late king, and Edward III. king of England, who aſpired to the throne in right of his mother. His pretenſions were eaſily ſet aſide, and Philip was confirmed in the regency, from which he ſoon ſtepped into the throne on the queen being delivered of a daughter; from which circumſtance he acquired the ſurname of "Fortunate." Thus the crown of France had deſcended in the Capetian family from father to ſon for eleven generations, and the ſucceſſive reigns had all contributed to extend the dominion and authority of the monarchs: they had ſhaken off their dependance on the clergy; they had reduced the power of the barons, and had eſtabliſhed the royal revenue on a more permanent foundation. After almoſt three centuries and a half, the immediate poſterity of Hugh Capet, as we have ſeen, expired in Charles IV. and the ſceptre was placed in the hands of the race of Valois.

Philip was almoſt immediately involved in a war, yet he boldly ſummoned his rival, Edward of England, to yield him homage for the lands which he held in France. The Engliſh monarch paſſed the ſeas, and appeared bare-headed without

arms

arms or ſpurs, before a prince whoſe equal he conſidered himſelf: but his mind, indignant at the humiliating act, revolted, and war was immediately kindled between the two nations; and he who had been ſeen in France as a vaſſal, marched into it at the head of a numerous army. His moſt conſiderable ally was James d'Arteville, a brewer of Ghent, under whoſe auſpices the Flemings had acquired a degree of independence unknown in an age when the common people were almoſt univerſally enſlaved by feudal inſtitutions. With d'Arteville, therefore, as a leader, they were very ready and anxious to oppoſe the power of Philip. They adviſed the king of England to aſſume the title of king of France. A long and bloody conteſt enſued, in which the Engliſh were very generally ſucceſsful. Philip was under the neceſſity of ſecuring himſelf againſt the power of his rival by new alliances, and at length was reduced to that exhauſted ſtate that for ſome time he was incapable of making any oppoſition. To recruit his finances he laid a heavy duty on ſalt, which cauſed ſo much offence as nearly to excite a rebellion; but having aſſuaged the diſcontents, he found his hands ſtrengthened, and was ſoon enabled to bring into the field 100,000 men, whoſe proweſs was farther raiſed by the preſence of the dukes of Normandy and Burgundy. The Engliſh were therefore compelled to ſtand upon the defenſive. One fortreſs after another ſurrendered to the French, till nothing appeared but a total extinction of the power of England upon the continent. In this ſituation Edward reſolved to bring relief in perſon to his diſtreſſed ſubjects and allies, and embarked for that purpoſe in 1346 at Southampton, with a large army on board of one thouſand ſail of different bulks and burdens. He carried with him the chief, and indeed the flower of the nobility and great men of the country, and his eldeſt ſon the prince of Wales, a youth of fifteen years of age, ſince celebrated in hiſtory as the "Black Prince." The army which the king now took with him conſiſted of 4000 men at arms, 10,000 archers, 10,000 Welch infantry, and 6000 Iriſh; all of whom he landed ſafely at La Hogue, a port of Normandy, which country he determined to make the ſeat of war. The Engliſh had no ſooner landed than they ſpread terror and devaſtation all round them, and an univerſal conſternation reached the French court. The city of Caen was taken and plundered by the invaders, and all the villages and towns, even to Paris, ſhared the ſame fate; and the French had no other reſource but by breaking down their bridges to attempt a ſtop to the career of the Engliſh. Philip was not, however, idle or negligent in making preparations: he had ſtationed an army on the oppoſite ſide of the river Somme, over which Edward was to paſs; while he himſelf, at the head of 120,000 fighting men, advanced to give the Engliſh battle. Thus expoſed to the danger of being incloſed and ſtarved in an enemy's country, the king publiſhed a reward to any that ſhould bring him intelligence of a paſſage over the river. This was diſcovered by a peaſant of the country, and Edward had juſt time to get his whole army over the ſtream when Philip appeared in his rear. The famous battle of Creſſy was now fought, in which the French were completely defeated with the loſs of thirty thouſand ſoldiers, eleven princes, eighty barons, and twelve hundred knights. Edward immediately beſieged the town of Calais, which ſurrendered, and remained in poſſeſſion of the Engliſh 210 years. From the commencement of this war Philip had invariably ſhewed himſelf deſirous of peace, and the victory obtained over him at Creſſy increaſed his anxiety in this reſpect; and fortunately for him, the expences incurred by his opponent were ſo great that he could no longer ſuſtain the conteſt. A truce of three years was accordingly concluded through the mediation of the court of Rome: at the ſame time Philip met with ſome recompence for the loſſes which he had ſuſtained, by the acquiſition of Dauphiny, which had been bequeathed to him by the duke on condition that the eldeſt ſons of the kings of France ſhould take the name of Dauphin. Soon after this event the king himſelf, who had been ſome time a widower, was married to Blanch, the daughter of Philip count of Evreux, and Jane queen of Navarre. But he died within a year of this union, in the fifty-ſeventh year of his age, and the twenty-third of his reign. On the death of Philip, his eldeſt ſon John took poſſeſſion of the kingdom; but ſcarcely was he ſeated on the throne, when he diſguſted his nobility by an unſeaſonable act of ſeverity. Robert de Brienne, count of Eu and Guiſnes, had been taken priſoner by the king of England at Caen, and under pretence of negociating his ranſom had paſſed ſeveral times between France and England; but being accuſed of a treaſonable correſpondence with Edward, he was, by order of his ſovereign, ſuddenly arreſted, condemned, and beheaded, without the form even of trial. Having been conſtable of France, the ſword, the badge of office, was delivered to Charles de la Carda; but his fate was equally unfortunate with that of his predeceſſor, being ſoon after aſſaſſinated by Charles king of Navarre. On the expiration of the truce Edward renewed hoſtilities, being perfectly intent upon the conqueſt of France; but having, by means of his ſon, made an unſucceſsful attempt, he recalled his army. After the departure of which, John aſſembled the ſtates at Paris, explained to the deputies the diſtreſſed ſituation of his finances, and exhibited ſo fully and ſatisfactorily the neceſſity of aſſiſting him in the defence of the kingdom, that they conſented to maintain an army of 30,000 men during the war. To raiſe the neceſſary ſupplies, the ſalic law, as it was called by way of ridicule, or the duty on ſalt, was revived, and many other impoſts that bore heavy on the people; but at the ſame time they appointed a committee of their own number to take care that the money was ſolely appropriated to the public ſervice. The ſatisfaction which John received from theſe grants was ſoon damped by the news that the prince of Wales had invaded his country, and taken ſome important places. Though alarmed, he did not ſit down in deſpair, but aſſembled an army of 60,000 men to ſtop his progreſs, and with the hope of intercepting him. Edward at firſt thought of retreating, but finding that project impoſſible, he determined calmly to wait the approach of the enemy; and notwithſtanding the diſparity of forces, to commit all to the hazard of a battle. At Maupertuis, near Poictiers, the armies came in ſight of each other. The French monarch might, with a common ſhare of prudence, have ſtarved the enemy into any terms he thought proper to impoſe; but ſuch was the impatient valour of the French nobility, and ſuch their certainty of ſucceſs, that he was forced to act in the aggreſſive. While both armies were drawn up in order of battle, and waiting only for the fatal ſignal to commence the bloody attack, they were ſtopped for a moment by the appearance of the cardinal Perigord, who attempted to be a mediator between them. John, however, who felt certain of victory, refuſed to liſten to any terms, unleſs the baſis was the reſtitution of Calais. The Black Prince, exaſperated at the propoſal, boldly declared he was ready to hazard every thing rather than ſeek ſafety on ſuch degrading terms. The onſet was deferred till the next morning, for which both ſides waited with anxious and awful ſuſpence. At length the trumpet ſounded, and a horrible carnage enſued; and in the end the French monarch

was

was made priſoner, and conducted as ſuch to the metropolis of England. The government of France now fell into the hands of the king's eldeſt ſon, Charles, who was afterwards king under the title of Charles V. a prince now but fifteen years of age. This youth poſſeſſed great talents, and amidſt the moſt dreadful conteſts he gained the aſcendancy by his wiſdom and activity; opened the eyes of the people to their true intereſts; brought them back to moderation, and after a time negotiated a peace with the Engliſh, by which king John was permitted to return to his native country. The king, however, finding the affairs of the ſtate ſo well conducted by his ſon, left them in his hands, and rarely interfered with his authority, or even advice, but on very important occaſions. After the peace was accompliſhed, the diſbanded ſoldiers, having no regular employment to which they could turn their attention, united under chiefs of their own election, and committed all kinds of atrocities. When by plunder their leaders had acquired ſufficient riches, they retired to enjoy their wealth, but ſtill there remained many wandering ſoldiers, who were eſteemed the beſt, but the moſt profligate in Europe. Theſe the king would have aſſembled in a body, and made another cruſade, but the treachery of one of his ſons obliged him to become a ſecond time a captive in England, where he died. He obtained the ſurname of "Good," which, notwithſtanding his imprudence and misfortunes, he ſeems to have juſtly merited. By his actions, as well as his words, he declared "that if honeſty and honour were loſt on the earth, it ought to be found again in the hearts of kings."

Charles V. the ſucceſſor to John, delivered France from the banditti by whom it had been ravaged, by driving the plunderers into Spain under the command of Gueſelin. At Avignon, this leader, pretending that he was at the head of 30,000 cruſaders, going to make war upon the infidels, demanded of the pope full abſolution from their ſins, and 200,000 francs to defray the expences of their journey. The former, as it coſt nothing, was readily granted, and the money was, after a little delay, raiſed by a tax on the people, which, however, Gueſelin refuſed to accept, inſiſting that the whole ſum of money, as well as the ſpiritual benediction, ſhould be furniſhed by the pope and cardinals. Having thus delivered his kingdom from theſe plunderers, Charles eſtabliſhed in it a proper police and good order, recovered ſome of the provinces from the Engliſh, and though he rarely appeared in perſon at the head of his troops, yet Edward ſaid of him, "No king, who interfered ſo little with military operations, ever did me ſo much injury. This monarch, who obtained the title of "Wiſe," did every thing in his power to baniſh ignorance from his kingdom, and to diffuſe through it a taſte for learning. He ſhewed great reſpect for thoſe by whom it was cultivated, and who were denominated "clerks." "Theſe," ſaid he, in the true ſpirit of patriotiſm, "cannot be too much honoured; while wiſdom is honoured, the kingdom will proſper; when it is baniſhed, it will fall to ruin." This monarch was the founder of that immenſe library that is now the glory of the French empire, and it is ſaid the moſt gratifying preſent that could be made him was a book. He took delight in the ſciences as far as they were then known, which was the only relaxation that he allowed himſelf from the cares of government. He died too ſoon for his country, at the age of forty-four, and was ſucceeded by his ſon Charles VI. who proved himſelf utterly incapable of the management of public affairs. Being a weak prince, the nobility contended for the adminiſtration, and convulſed the kingdom. Every ſpecies of miſery that ambition, avarice, diſcord, and rebellion could produce, combined to ruin the ſtate. The hiſtory of this period is a ſeries of dire and calamitous events. Contempt of the laws, alienations of the funds, acts of injuſtice and violence, are the ſignal exploits of this reign.

In the beginning of the next, Charles VII. was ſo much inclined to diſſipation, that he nearly loſt the whole of his kingdom; but either his own misfortunes, or the timely reproof of a general, on whoſe judgment he greatly relied, excited in him a conduct more worthy of his character, and he occaſionally was ſeen foremoſt among the ranks of his ſoldiers, and was more than once almoſt the firſt to mount a breach, and rallied in his own perſon troops ready to abandon their colours. He was, however, unfortunate, though brave, and borne down by the ſuperiority of the Engliſh arms. After a war of ſeven years, when Orleans, the only town left him by which he might ſupport his power in the centre of the kingdom, was beſieged, a country-girl, of the name of Joan of Arc, and ſince celebrated by the title of the maid of Orleans, preſented herſelf to the governor, requeſted that ſhe might be ſent to the king, becauſe God had revealed to her, that under her command the ſiege ſhould be raiſed. She obtained her deſire, was preſented to Charles, headed his troops, and nobly performed all that ſhe had promiſed. Crowned with victory, and thinking herſelf ſuperior to misfortune, ſhe propoſed a journey to Rheims, although at that time it was in the hands of the enemy. Nevertheleſs, ſhe ſurmounted every obſtacle, entered the city, cauſed the king to be conſecrated, and then requeſted leave to retire, having accompliſhed her miſſion. At length the fortune of war, and the treachery of a French governor, threw her into the hands of the enemy, who, after inflicting upon her many cruel inſults, cauſed her to be burnt alive in the market place of Rouen. After the conſecration of Charles VII. his reign was a continued ſeries of victories; he expelled the Engliſh from France, and rendered himſelf highly uſeful to the intereſts of his country. He died in the ſixtieth year of his age, and was ſucceeded by Lewis XI. in the year 1460, who had been long ambitious of taking the reins of government. He was reckoned one of the greateſt politicians that ever exiſted, but his moral character was deteſtable, and as a king, he was inſidious, abſolute, and tyrannical: he was frequently diſturbed by the factions of the nobles; but, in dividing, he was enabled to diſconcert and defeat their beſt plans: and notwithſtanding all the attempts of his ſubjects to the contrary, he ſecured himſelf on the throne, and extended the royal prerogative by policy and rigour. He acted, however, more like a conqueror than the legitimate ſovereign of good and faithful ſubjects. He cauſed ſeveral thouſands of them to be deſtroyed without the form of trial, and committed, or cauſed to be perpetrated, inhumanities and cruelties that are ſcarcely to be credited. By theſe he broke the ſpirits of the French nobility, and gradually extended the power of the crown beyond all bounds; ſo that at laſt it was only limited by the ſovereign's pleaſure. From this time the people were accuſtomed to ſubmit entirely to the voice of the king as the only legiſlator; and being always obedient in matters of the greateſt conſequence, they cheerfully contributed whatever ſums were required to fulfil the king's pleaſure. This king died deteſted by his ſubjects; and during his laſt illneſs he was ſo much alarmed at the proſpect before him, that he was ſurrounded by relics, and a ſaint was brought from Calabria to reſtore him to health: but neither medicine, nor prayers, nor pious proceſſions, could avail or avert the impending ſtroke. He expired in the year 1483, after a reign of 23 years. His ſucceſſor Charles VIII. made an expedition

to

to Italy in order to ſecure the conqueſt of Naples, which he claimed as his right: with his army he overwhelmed the country like a torrent, aſtoniſhed the natives with the unuſual arms which they bore, and with which they could cleave a man aſunder, almoſt with a ſingle blow. In ſix weeks the king traverſed the whole country, and made himſelf maſter of the kingdom of Naples. Such an inſtance of extraordinary good fortune ſeemed miraculous; and he was, in thoſe times, reckoned an inſtrument raiſed by God to deſtroy the execrable tyrants with which Italy was at that time infeſted. Had Charles made uſe of this prepoſſeſſion in his own favour, and known how to turn it to his account, he might have raiſed himſelf to the higheſt pitch of celebrity. But he abandoned himſelf to pleaſure, of which ſurrounding princes took the advantage, combined againſt him, and diveſted him of his new kingdom in as ſhort a time as he had employed in the acquiſition of it. He died at the age of 28.

Louis XII. the ſucceſſor to Charles, rendered himſelf formidable to the republics of Genoa and Venice: he had however to contend with pope Julius the Second, who was ſaid to be a better ſoldier than eccleſiaſtic. This holy father at one period was ever on the march, took cities, and won battles, till he met with a defeat from the French: hearing that his enemy had obtained an important victory in which his own intereſt was concerned, he threw away a book which he held in his hand, and indignantly ſcoffed at his maker on account of his partiality, as he deemed it, for the French. Lewis put an end to much oppoſition, and converted many dangerous enemies into faſt friends by the marriages which he negociated. To Ferdinand of Spain he offered his daughter for either of his grandſons, and propoſed to renounce in favour of the marriage his claims on Milan and Genoa. This propoſal was accepted, and Louis himſelf married the princeſs Mary, ſiſter to Henry VIII. of England: after this he ſurvived but a very ſhort time, and was ſucceeded by Francis I. early in the year 1515. This prince had great abilities and many defects, which proved the ſources of heavy and long continued misfortunes. After the example of his predeceſſors, he invaded Italy without ſucceſs. When he aſcended the throne, he was young, ambitious, and a candidate for the imperial crown in oppoſition to Charles V. which was the cauſe of hatred between the rival princes. Charles deprived Francis of ſeveral of his allies, among whom was Henry VIII. of England. The French and Engliſh monarchs, at an interview at "Le Champ du drap d'Or," had ſworn to maintain a ſincere friendſhip, but enticed by Charles, Henry forgot his oath, and took part againſt his friend. Francis, in an attack upon Pavia, was beaten and taken priſoner. The conqueror did not exhibit towards the fallen monarch that generoſity and frankneſs which he promiſed: he, it is true, after two years' confinement, ſet him at liberty, but it was on ſuch conditions as could not fail to produce a new war. A league, formed with the pope, the Venetians, and Henry VIII. againſt Charles, was ſoon diſſolved by the peace of Cambray. Several negociations with the Proteſtants in Germany having proved fruitleſs, hoſtilities were renewed; but by the intervention of the pope, a truce for ten years was concluded; war however broke out before half that period was elapſed: the emperor obtained the aid of ſeveral neighbouring princes, and penetrated into the heart of France, but, notwithſtanding his ſucceſs in the outſet, he was conſtrained to propoſe terms of accommodation, which were readily accepted by Francis. New ſchemes of ambition were formed by the one, and new meaſures, for rendering theſe ineffectual, were adopted by the other. In the midſt of theſe plans and operations, a lingering illneſs ſeized on Francis, which put a period to his life in the thirty-third year of his reign. He was ſucceeded by Henry II. of whom no memorable acts are recorded; but during his reign the people of Guienne rebelled againſt the government on account of the oppreſſive conduct of the officers who levied the ſalt tax, and were with difficulty brought to ſubmiſſion. After this, the king began to execute the edicts which had been made againſt the Proteſtants with the utmoſt ſeverity, to cauſe multitudes of them to be burnt, and he is ſaid even to have taken pleaſure in the ſavage ſpectacle. Towards the concluſion of the reign peace was re-eſtabliſhed in Europe, by the famous treaty of Chateau-Cambreſis, in which almoſt every prince of Chriſtendom was comprehended; and ſoon after the king was killed at a tournament by count de Montgomery, who was reckoned one of the ſtrongeſt knights in France, and who had done all in his power to avoid this encounter with the monarch. The reign of Francis II., ſucceſſor to Henry II., was remarkable only for the perſecution of the Proteſtants, which became ſo grievous, that they were obliged to take up arms in their own defence. This occaſioned ſeveral civil wars, of which the firſt commenced in the reign of Charles IX. who ſucceeded to the crown in 1560. Theſe conteſts were all memorable in ſome way or other, and have been noticed in hiſtory by the circumſtances that preceded or attended them. The maſſacre of the Proteſtants at Vaſſi in 1562 by the duke of Guiſe's attendants was the ſignal of the firſt:—the intrigues of Catharine, and the cruelty of the duke of Alva, proved the occaſion of the ſecond:—an attempt to ſeize the prince of Condé and Coligny, the leaders of the Proteſtants, paved the way to another rupture:—the infamous maſſacre of St. Bartholomew, 1572, brought on a fourth civil war;—and laſtly, a powerful faction was formed againſt the houſe of Guiſe, and hoſtilities were renewed, but at the commencement of this war Charles was removed by a violent diſorder. He lingered indeed for ſome time under the moſt terrible agonies both of body and mind: and it is ſaid that after the dreadful maſſacre of St. Bartholomew's day he had a perpetual fluſh and fierceneſs of countenance which he never had before. His ſleep was of ſhort duration, and perpetually interrupted. He waked frequently in the utmoſt agonies, and no arts could be invented to give him reſt. He died at the age of 24.

Henry III. brother to Charles, ſucceeded to the crown, but, being immerſed in pleaſures, he left the ſole direction of the public affairs to his mother. A new faction, called the ſacred league, was formed for the defence of the Catholic religion, which was animated by the duke of Guiſe, and ſupported by the court of Spain. They united their force, and combined with one mind to ſuppreſs it, and the moſt terrible conſequences enſued. Hoſtilities and pacifications quickly ſucceeded one another, till at length the king was nearly depoſed by the Guiſes, whom he cauſed to be aſſaſſinated, when the party were in the act of driving him from the kingdom. This murder inflamed the confederates with the utmoſt reſentment, who publicly declared that Henry had, by the atrocity of the act, forfeited the crown, and was an enemy to religion: they cauſed his name to be eraſed from the public prayers, and openly declared that it would be a meritorious act to put him to death. James Clement, a Dominican friar, engaged to perpetrate the deed, and actually ſtabbed the monarch as he was reading ſome letters at St. Cloud. Thus died Henry III. a man endowed with ſuch qualities as would have been judged worthy of a throne had he never been called to that high ſituation. In him the family of the Valois ended.

Before the king's death, he had nominated as his ſucceſſor Henry Bourbon king of Navarre; to this honour he had a

title which he derived from Lewis XI. who had been dead more than 300 years; nevertheleſs, he was oppoſed by the party of the Guiſes, on account of the ſupport which he had uniformly given to the reformed religion: this was the only obſtacle to the acknowledgment of Henry's claims by the greateſt part of his ſubjects, and in the end it gave riſe to a civil war. Henry encamped before Paris, of which he might have made himſelf maſter by famine, had he refuſed to grant a paſſage to a multitude of old men, women and children, who were ordered to depart the city to ſave proviſions. For this act of generoſity the king was blamed by his generals, but he nobly replied, "That he would rather endure the reproaches of the whole world than thoſe of his own heart." At length, perceiving that the Catholics were ſeeking foreign aid, and that there would be no termination to theſe evils unleſs he renounced the proteſtant religion, he, by the advice and earneſt perſuaſion of his miniſter the great duke of Sully, declared himſelf a catholic, and accordingly abjured his former faith at St. Dennis, and was crowned king at Chartres in 1594. This change put him in poſſeſſion of the whole kingdom, but the proteſtants were at firſt indignant at his converſion; nevertheleſs they were appeaſed by the celebrated edict of Nantes, which re-eſtabliſhed, in a moſt ſolid and effectual manner, all the favours that had ever been granted to the reformed by other princes, and adding ſome which had not been thought of before, particularly the allowing them a free admiſſion to all employments of truſt, profit and honour, the eſtabliſhing chambers in which the members of the two religions were deemed equal, and the permitting their children to be educated without conſtraint in any of the univerſities. Having concluded a peace with Philip II. of Spain, he beſtowed all his attention on the improvement of his kingdom, by reforming its laws, regulating its finances, encouraging agriculture and manufactures, enlarging and embelliſhing cities, and finally reconciling, in a great meaſure, the partiſans of contending religions. In all his beneficial ſchemes he found an able and faithful aſſiſtant in his miniſter the duke of Sully. Theſe two great men, ſays the hiſtorian, ſeemed to have been born for one another; greatneſs and true glory were the conſequences of their united endeavours to promote the public good. The ſchemes of reformation, projected by this king and his miniſter, were intended to be carried far beyond the boundaries of France: they were anxious to new-model the whole of Europe, and reduce all its powers into a kind of Chriſtian republic, by rendering them as nearly as poſſible of equal ſtrength. That this republic might be maintained in perpetual peace, they propoſed to bring all their differences to be decided before a ſenate of wiſe, diſintereſted, and able judges, and then they ſuppoſed it would be no difficult matter to overturn the Ottoman empire. With a view probably of executing this project, but under the pretence of reducing the exorbitant power of the houſe of Auſtria, Henry made immenſe preparations by ſea and by land, when he was aſſaſſinated at the age of 57 by Ravaillac, an inſane fanatic. The life and character of this monarch have been tranſmitted to poſterity by the pen of his miniſter, to which we ſhall again have recourſe in the article HENRY.

On the death of Henry IV. the queen-mother, Mary de Medicis, aſſumed the regency during the minority of Lewis XIII., which was only remarkable for cabals and intrigues of the courtiers. France, which under Henry had riſen from a ſtate of miſerable anarchy to the higheſt pitch of glory, ſunk now into a wretched ſtate of weakneſs. In 1617 the king aſſumed the government himſelf, baniſhed the queen-mother, cauſed her favourite Marſhal d'Ancre to be killed, and choſe for his miniſter the celebrated Cardinal Richelieu. This wiſe miniſter reconciled the contending parties, and re-eſtabliſhed the dignity of the monarchy. The proteſtant party attempted to throw off their allegiance, and eſtabliſh an independent ſtate, of which Rochelle was to be the capital. The Dutch vigorouſly aſſiſted Richelieu in ſubduing the proteſtants, while the Engliſh ſent out a fleet in aid of the inhabitants of Rochelle, who maintained their ground for a whole year againſt the French with the cardinal at their head. At length, however, they were forced to ſurrender, and this, with all the proteſtant cities of France, were ſtripped of their privileges, and their religion effectually cruſhed. Lewis XIII. entered completely into the views of his miniſter, who influenced the politics of all the courts of Europe: the talents of Richelieu were equally and ſucceſsfully diſplayed in active war, in foreign negociations, and in his domeſtic arrangements; yet at this time a conſpiracy was forming againſt him. Mary de Medicis was jealous of the man ſhe had raiſed, and was deſirous of deſtroying the idol ſhe had formed. The duke of Orleans ſought to ſupplant the miniſter; but, with aſtoniſhing intrepidity of mind, he repreſſed the conſpiracy, ſeized the Marſhal de Marillac, one of his moſt dangerous enemies, at the head of his army, and put him to death. Orleans, apprehending a ſimilar fate, fled the kingdom. Mary was arreſted, and ended her days in a voluntary exile at Bruſſels. Amidſt this turbulence, both of foreign war and domeſtic cabal, Richelieu cultivated the purſuits of literature; he was, as we have ſeen in many of our biographical articles, a liberal patron of the ſciences, and of thoſe who devoted their lives to the extenſion of knowledge. His adminiſtration advanced the glory of France as a monarchy. He died in 1642, victorious, it is ſaid, over the enemies and the liberties of his country. He expired almoſt immediately after his arrival at Paris, where a breach was made in the walls to admit his litter in a ſort of triumph. The death of the miniſter was ſhortly after followed by that of his ſovereign in 1643. He was ſucceeded by

Lewis XIV. who was only five years of age when he came to the crown of his father. The queen-mother, Anne of Auſtria, was appointed regent during the minority, who choſe for her miniſter Cardinal Mazarine, whoſe violence excited new diſorders in the ſtate, which cauſed his baniſhment from Paris; but though retired to the imperial dominions, he influenced and over-ruled the meaſures of the court of France. In 1652 Mazarine reſumed his ſtation as miniſter, which he continued till his death in 1661, when the monarch began to act completely for himſelf, and entered on a vigorous diſplay of his talents. The finances, which had long been in extreme diſorder, were admirably regulated by Colbert; and the commerce and manufactures of the kingdom, wiſely encouraged by government, were ſoon in the moſt flouriſhing ſituation. The famous canal that joins the Bay of Biſcay with the Mediterranean was cut; all the ſea-ports were fortified and enlarged, and the internal police ſtrictly enforced by the monarch. The arms of France aided at the ſame time England againſt the Dutch, Germany againſt the Turks, and Portugal againſt Spain. On the death of Philip IV. Lewis, who had already acquired the addition of *Grand* to his other titles, under pretence that Spain had failed in payment of the dowry of his queen, beſieged and took Liſle with ſeveral fortified cities in Flanders. The king marched himſelf at the head of his armies, but the glory of the conqueſts was owing to Turenne and Vauban. The ſtrength and proſperity of the kingdom were ſtill augmented under the adminiſtration of Colbert. The parties in Holland between the Stadtholder and thoſe who eſpouſed the ſide of the virtuous DE WITTS (which ſee), tempted Lewis to undertake the conqueſt of that country, and England,

land, Germany and Sweden favoured his project. He over-ran ſeveral of the provinces, and advanced almoſt to the gates of Amſterdam, when the Dutch overflowed the country by letting in the ſea, and the French were obliged to retreat. At length the confederate powers began to be jealous of the aſcendancy of France, and the prince of Orange had ſufficient influence with England and the houſe of Auſtria to obtain an alliance in aid of the republic. The arms of Lewis, however, ſtill continued ſucceſsful, and the peace concluded at Nimeguen in 1678 was in favour of France. The armies which France kept on foot, either foreſeeing or meditating a new war, enabled the ſovereign to humble the pretenſions of Algiers and Genoa. The former was forced to releaſe, without any remuneration, all the French ſubjects whom they had made ſlaves, and promiſed to exerciſe that power no more: the latter, more than half demoliſhed by bombs, could not ſuſpend the ardour of the beſiegers but by ſending its doge and other principal officers to make humble excuſes. Having annexed ſeveral principalities to his vaſt dominions, having obtained very important ſucceſſes in a new war, and having laid the Palatinate waſte, and in ruins, and having likewiſe revoked the edict of Nantes, the whole continent of Europe, with England at the head, became violent againſt the towering ambition of Lewis. Nevertheleſs he maintained his ground, though he experienced ſome ſevere checks; his navy was deſtroyed at La Hogue, the coaſts were infeſted by the Engliſh ſhips, which deſtroyed Havre, and reduced Dieppe to aſhes. Victory was, however, the companion of Lewis by land; but the numerous armies which he kept in the field depopulated the kingdom, and occaſioned a famine. The people ceaſed to admire, and feeling the dire effects of war, they began to murmur. To famine was added the calamity of civil war. The proteſtants revolted, becauſe their worſhip was ſuppreſſed, their churches demoliſhed, and their miniſters baniſhed. France loſt half a million of its beſt and moſt induſtrious ſubjects, and the name of Lewis the Great was execrated all over Europe. Now the united forces of England and Auſtria, under the command of Marlborough and Eugene, (ſee CHURCHILL and EUGENE,) prevailed, and rendered the concluſion of this reign as miſerable, as at the commencement it had been fortunate. From the year 1702, till nearly the cloſe of his reign, which happened in 1715, Lewis ſuſtained a ſeries of defeats and calamities. As a patron of literature and learned men, he yielded to none of his contemporaries. It was his higheſt honour, that he diſcerned and recompenſed merit wherever he found it; and France was in his time equally illuſtrious by the military talents of her generals, and by the progreſs which ſhe made in the arts and ſciences. See LEWIS.

By the laſt will of Lewis XIV. the government of the country devolved on his great grand-ſon, who was at the deceaſe of the monarch only five years old, and the regency was ſeized by Philip duke of Orleans, whoſe authority was ſanctioned by the parliament of Paris. This prince gave a turn to the manners of the court. Inſtead of that grave and auſtere appearance which had prevailed in it, nothing was now ſeen but levity and diſſipation. Lewis XIV. never formed any connection with the Engliſh, but ſuch as was indiſpenſably neceſſary; the regent abandoned himſelf to them entirely, and was guided by their councils, with the hope, no doubt, to ſecure their protection and favour, in caſe the young king ſhould die, whoſe health was exceedingly precarious. The regent himſelf, however, died ſuddenly, and was ſucceeded by the duke of Bourbon Condé, who endeavoured to enrich himſelf by the ruin of the ſyſtem at the head of which he was placed. The people murmured at his depredations, but he diſregarded their complaints, expecting the ſupport of the king. In this he was diſappointed; Lewis, when he was capable of acting for himſelf, diſmiſſed and diſgraced him, and he was ſucceeded by cardinal Fleury, who was a man of a moſt amiable diſpoſition, and who took the reins of government at an age when moſt men retire from the world. (See FLEURY.) About this time an artful adventurer, Riperda, raiſed himſelf from obſcurity to the government of Spain, by ſecretly negociating a treaty between the courts of Madrid and Vienna. To counterbalance this treaty, an alliance was formed between France, England, and the king of Pruſſia. Theſe diſſentions gave but little interruption to that general tranquillity which Europe enjoyed from the peace of Utrecht till the year 1734. At that period a flame broke out, in conſequence of the death of Auguſtus II. the king of Poland, and ſoon ſpread itſelf through every part of Europe. Lewis wiſhed to place on the throne of that country his father-in-law Staniſlaus, but the Ruſſians and the houſe of Auſtria eſpouſed the cauſe of the elector of Saxony. A war was commenced, and after it had been carried on with various ſucceſs, peace was concluded at Vienna, by which it was agreed that Staniſlaus ſhould retain the title, but renounce the authority of king of Poland, and ſhould be put in poſſeſſion of Lorraine and Bar. By this treaty the act regulating the ſucceſſion to the empire, called the "Pragmatic Sanction," was guaranteed by France, as it had formerly been by Holland, England, and other European powers. On the death of Charles VI. his daughter Maria Thereſa was not allowed to remain long in quiet poſſeſſion of that vaſt inheritance which her father had been ſo anxious to ſecure for her. A number of princes laid claim to different parts of her dominions, and the confuſion which had been thrown by the feudal ſyſtem over the right of ſucceſſion to kingdoms, enabled each claimant to give the appearance of juſtice to his pretenſions. Charles Albert, elector of Bavaria, laid claim to the ſucceſſion of Bohemia, in virtue of the will of Ferdinand I., but while he and other princes were labouring to eſtabliſh the juſtice of their demands, the ſucceſsful invaſion of Sileſia by the king of Pruſſia, at the head of 30,000 men, invited other powers to take up arms, and ſhewed the ſeveral competitors that the logic of war could effectually maintain their pretenſions. Notwithſtanding the pacific diſpoſition of cardinal Fleury, France did not long remain an idle ſpectator of theſe conteſts. This miniſter had the mortification, juſt before his death, to ſee the kingdom involved in calamities, from which it had been the great object of his life and adminiſtration to preſerve it. To check the ambition of the houſe of Auſtria, France united with Pruſſia, Saxony, and Poland, in ſupport of the pretenſions of the elector of Bavaria, and conceived the deſign, not only of putting this weak prince in poſſeſſion of Bohemia, but of raiſing him to the imperial throne. Charles Albert accordingly took the field at the head of the French army, and quickly penetrated into Auſtria, but inſtead of conducting his troops to Vienna, or of purſuing the queen, who had fled for ſhelter to Hungary, he was induced, by his impatience to obtain the titles of ſovereign power, to croſs the Danube, and invade Bohemia. This was in the autumn of 1741. Prague immediately ſubmitted, and at this city the conqueror was crowned, who then marched to Frankfort, where his vanity was amply gratified by receiving the imperial crown under the name of Charles VII. While this prince was ſoaring to the ſummit of greatneſs in Bohemia and Germany, the king of Pruſſia conquered Moravia, but the ſituation of Maria Thereſa was more deplorable than can well be imagined. She did not however deſpair; the ſpirit of the brave Hungarians was rouſed by her magnanimity; her diſtreſs excited the com-

paſſion of the Engliſh; diſſentions among her enemies, who were too numerous to agree long in any general plan, and who were already intoxicated by the ſplendour of their victories, ſoon gave a turn to her apparently deſperate affairs. In 1742 ſhe ſent into the field a formidable army, recovered Auſtria, and even penetrated into Bavaria, and the new emperor, who ſeemed to have obtained a ſecure poſſeſſion of the imperial crown, ſaw himſelf, in a moment, ſtripped of his hereditary dominions. The marſhal de Belleiſle and marſhal Broglio, who commanded the French and Bavarian troops, were prevented, by mutual jealouſy, from forming any concerted enterprize, and being continually haraſſed by the army of prince Charles, brother to the grand duke, found themſelves gradually exhauſted, without coming to any deciſive action. The defection of the king of Pruſſia from the alliance with France, and his treaty with Maria Thereſa in the ſummer of 1742, completed the ruin of the emperor's fortune, and threw the whole burden of the war on the French. The French generals, unable to keep the field againſt a ſuperior army, retired under the walls of Prague; and as a refult, the marſhal Belleiſle was obliged to make a retreat, in which he obtained ſignal honour, it having been compared to the celebrated retreat of Xenophon. The queen of Hungary was crowned at Prague, on the 12th of May 1743; and the emperor was wholly unable to ſave Bavaria; but by a revolution as rapid as that which had placed him on the imperial throne, he ſaw himſelf deprived of all his dominions, reduced to the condition of a fugitive, and a miſerable penſioner on the bounty of France.

The two moſt powerful ſtates, which had hitherto acted as auxiliaries, now became the principal parties in the conteſt, and the war, which had originated in a diſpute about the ſucceſſion to the empire, became a violent ſtruggle for ſuperiority between France and England. They tried their ſtrength at the battle of Dettingen in 1743, and the Engliſh were decidedly victorious. France began now to tremble for her own ſafety, and feeling that energy which, in nations, as well as in individuals, is roufed by the appearance of extraordinary danger, ſhe employed all the arts of policy and warfare to avert the ſtorm with which ſhe was menaced. Among other powers, ſhe gained over to her ſide the king of Pruſſia, who began to dread that the rapid ſucceſs of the queen of Hungary might deprive him of all his conqueſts. The firſt ſymptom of the reſolute ſpirit which actuated the French councils was in a ſea fight off Toulon in 1744, in which the Engliſh were victorious, though no very deciſive advantage was gained over their opponents. But the exertions of France by land were more reſpectable. She fitted out four great armies in one year; of theſe the moſt conſiderable was deſtined for Flanders, and with it, Lewis himſelf made the firſt campaign, in which he obtained many ſignal victories, till he was ſtopped in his career by diſaſtrous news from his own country. Leaving therefore his conqueſts in Flanders, he flew to the protection of France, and when he arrived at Metz he had the ſatisfaction to hear that Frederic had poured an immenſe army into Bohemia, and another into Moravia; that he had forced Prague to ſurrender, and made 15,000 men priſoners of war. Here he was taken ſeriouſly ill, and his indiſpoſition filled the court and people with conſternation and grief; and his recovery cauſed the moſt rapturous joy throughout his widely extended kingdom. Charles VII. recovered Bavaria, but died ſoon after; war was however maintained by the oppoſing parties. Marſhal Saxe opened the campaign by the ſiege of Tournay, the ſtrongeſt of the barrier towns, which produced, as might have been expected, a general engagement. The event was glorious to France. The king and dauphin had their vanity gratified, by ſeeing their troops gain a complete victory at Fontenoy over the allied army of Engliſh, Dutch, and Hanoverians, conſiſting of nearly 60,000 men. In conſequence of this ſucceſs, Tournay, Ghent, Oudenarde, Bruges, Dendermond, Aeth, and even Oſtend itſelf, ſurrendered to the French king. The arms of France and Spain were no leſs ſucceſsful in Italy. But in a few months they were obliged to abandon their Italian conqueſts. In the Low Countries they were ſtill ſucceſsful; marſhal Saxe took Bruſſels in the middle of winter: Antwerp was taken by the king in perſon; Mons, Namur, and other places ſurrendered to the arms of France, till at length the entire conqueſt of Dutch Flanders was effected. The allies, every where unſucceſsful, ſolicited peace, which was readily granted by Lewis, who never ſeems to have felt the ardour and enthuſiaſm which form the conqueror and hero. A treaty was ſigned at Aix-la-Chapelle by the plenipotentiaries of England, France, Spain, Sweden, the queen of Hungary, the States-general, the duke of Modena, and the republic of Genoa. The baſis of this treaty, which was ſigned April 30, 1748, was the reſtitution, on both ſides, of all the places taken during the war. The articles of this peace were ill calculated to produce a permanent tranquillity. The vague and indefinite manner in which the boundaries of the ſettlements of both countries in America were fixed by the treaty of Aix-la-Chapelle, and the continual diſſentions and quarrels which this circumſtance naturally tended to produce, furniſhed the one nation with abundant occaſion for cenſure, and the other for recrimination; and, at laſt, produced an open rupture. Other powers ſoon became parties in this conteſt. The world ſaw with wonder England forming an alliance with Pruſſia; and France and Auſtria, thoſe powers whoſe mutual jealouſies had diſtracted Europe for two centuries, now connected themſelves by an union as intimate and cloſe as their former animoſity had been violent and implacable. The early events of this war were glorious for France in every quarter of the globe. Nothing was heard of in England, from all parts, but loſſes and misfortunes. Minorca was taken, admiral Byng was defeated at ſea, and conſtrained to take refuge under the walls of Gibraltar. In India and Canada they were equally unſucceſsful. The military genius of the nation, as well as the ſpirit of patriotiſm, ſeemed to be drowned in the clamour of faction. And the people, almoſt driven to deſpondency, ſaw a contempt of their arms gradually inſinuating itſelf among foreign powers, which was more mortifying to the national pride than all their calamities. About this time the parliaments fell under the diſpleaſure of the king by their perſecution of thoſe who adhered to the bull UNIGENITUS, which ſee. They proceeded ſo far in this oppoſition as to refuſe to regiſter certain taxes abſolutely neceſſary for the carrying on the war. By this the king was ſo irritated, that he ſuppreſſed the fourth and fifth chambers of inqueſts, the members of which had diſtinguiſhed themſelves by their oppoſition to his will. This created the moſt grievous diſcontents, and many of the principal members of the different parliaments reſigned their offices. An attempt was made by Damien to aſſaſſinate the king, who was ſlightly wounded, in the preſence of his ſon, and ſurrounded by his guards. The aſſaſſin was put to the moſt exquiſite tortures, in the midſt of which he perſiſted in declaring that he had no intention to kill the king, but that his deſign was only to wound him, in order that God might touch his heart, and incline him to reſtore peace to his dominions. This attempt upon his majeſty is ſuppoſed to have had ſome effect upon him, for he immediately altered his method of government, and accommodated matters with

his parliament. The peace concluded at Paris in the year 1763, though it freed the nation from a deſtructive, bloody, and, towards the concluſion, unſucceſsful war, did not reſtore its internal tranquillity. The parliament, eager to purſue the victory they had formerly gained over their religious enemies, now directed their efforts againſt the Jeſuits, who had obtained and enforced the bull unigenitus. That once powerful order, however, was now on the brink of deſtruction. A general deteſtation of its members had taken place throughout the world. A conſpiracy, formed by them againſt the king of Portugal, and from which he narrowly eſcaped, had rouſed the indignation of Europe; this was ſtill farther encreaſed by ſome fraudulent practices of which they had been guilty in France. Prejudices running very high againſt them, every miſchief, even to the attempt of Damien, was imputed to their contrivance or influence. Their ruin ſeemed to be certain, when the king interfered, and ſuſpended all proceedings againſt them for a year; a plan of accommodation was drawn up, and ſubmitted to the pope and general of the order, but the latter, feeling the degradation to which his party muſt be expoſed, entirely overthrew, by his own hauteur, the hope of reconciliation. The king now withdrew his protection, the parliament redoubled their efforts againſt them, and the ſociety was finally diſſolved, its members declared incapable of holding any clerical or municipal offices: their colleges were ſeized, their effects confiſcated, and their order annihilated.

The parliament next made an attempt to ſet bounds to the power of the king himſelf. They refuſed to regiſter an edict which Lewis had iſſued for the continuance of ſome taxes which ſhould have ended with the war, and likewiſe to agree to another by which the king was enabled to redeem his debts at an adequate price. The court attempted to get the edicts regiſtered by force, but the parliaments every where ſeemed inclined to reſiſt to the laſt. In 1766, the parliament of Britanny refuſed the crown a gift of 700,000 livres, in conſequence of which they were ſingled out to bear the weight of royal vengeance: the king, however, yielded his rights as he was pleaſed to conſider them, and publiſhed a general amneſty. The parliaments increaſed their claims, and affected to deſpiſe the royal clemency, which exaſperated Lewis ſo much that he ordered the counſellors of the parliament of Britanny, who had refuſed to reſume their functions, of which he had deprived them, to be included in the liſt of thoſe who were to be drafted for the militia; and thoſe upon whom the lot fell were obliged immediately to join their reſpective regiments; the reſt being employed in forming the city-guard. The parliament of Paris remonſtrated ſo freely upon this conduct of the king, that they fell under his cenſure; and the monarch, aſſuming the authority of his anceſtors, explicitly declared that he would ſuffer no earthly power to interfere with his will; and the parliaments were for the preſent intimidated into ſubmiſſion. Lewis next engaged in a conteſt with the pope, and claimed as his own hereditary right the territories of Avignon and Venaiſſin, and while the pontiff denounced his unavailing cenſures againſt him, one of his generals, with a ſingle regiment of ſoldiers, drove out the troops of the pope, and took poſſeſſion of the territories in queſtion. He now engaged in the reduction of the iſland of Corſica, which had been transferred to the crown of France by its ancient maſters the Genoeſe. The iſlanders, little diſpoſed to comply with the wiſhes of thoſe who ſold and who purchaſed their country, reſiſted with the utmoſt bravery the French power; and it was not till the termination of a ſecond campaign, and after the loſs of many thouſands of the beſt troops in France, that the iſland ſubmitted: little was it imagined that at this moment, the future maſter of France, and conqueror of almoſt the whole continent of Europe, was a nurſling of an undiſtinguiſhed and mean Corſican family; he who has torn kings from their thrones, and ſupplanted, or overthrown the ancient dynaſties of the world, was then overlooked and probably deſpiſed for the lowneſs of his condition, and the poverty of his progenitors.

The finances of France were at this time in a moſt deplorable ſtate; many of the great commercial companies of the country were involved in bankruptcy, which brought a ſimilar calamity on moſt of the principal merchants and traders. The miniſter, the duc de Choiſeuil, by one deſperate ſtroke, reduced the intereſt of the funds to one half, and at the ſame time took away the benefit of ſurvivorſhip in the tontines, by which the national credit was greatly affected; the diſputes between the king and his parliaments revived, and became more bitter than ever. Lewis again proved victorious, expelled his parliaments, cauſed others to be appointed who were more ſubſervient to his will, and thus every appearance of oppoſition was ſilenced by the abſolute authority of the king. In the midſt of this plenitude of power, his health declined, and his end was evidently approaching; but the immediate cauſe of his death, which happened in 1774, was the ſmall-pox, which he had taken from one of his miſtreſſes. He was ſucceeded by Lewis XVI. who was then twenty years of age, and to ſecure himſelf againſt the diſeaſe which had proved fatal to his predeceſſor, he ſubmitted to inoculation, as did other branches of the royal family, which rendered this proceſs not only faſhionable among the great, who are ever ready to imitate the court, but tended more than any other circumſtance to remove the prejudices of perſons in the inferior ranks and ſtations of ſociety. The king, as ſoon as he had recovered his health, applied himſelf moſt diligently to the reconciliation of the differences which had ſubſiſted between the court and the people. He removed miniſters whoſe conduct had been marked by arbitrary and illegal acts, and he recalled the old parliaments who had been ignominiouſly diſmiſſed by the late king. He declared, in one of his firſt ſpeeches, that while it was his determination to maintain his royal prerogatives entire, it was his wiſh and moſt anxious deſire to bury in oblivion all paſt grievances. Still it was evident that he meant to reduce the power of the parliaments to a mere cypher; he ſuppoſed that, under his wiſe management, they would be contented with the name without the reality; but his ſubjects were now too enlightened to ſubmit to the decrees of a ſovereign, when they interfered with the rights of the people. He, by his own authority, aboliſhed ſome oppreſſive taxes; and ſhortly after, the parliaments contended that they, by right, had, and ought to have, the ſole power of judging what ought and what ought not be impoſed on the ſubject.

At this time the finances of the country being in a deplorable ſtate, M. Turgot, a gentleman poſſeſſed of ſingular integrity and induſtry, had been appointed to the management of this branch of government; but notwithſtanding his zeal and induſtry, united to other qualities more highly to be appreciated, though more rarely to be found in a miniſter of finance, he had not been able to command the confidence of the country. He was accordingly obliged to reſign his office, and was eventually ſucceeded by M. Neckar, by birth a Swiſs, and a Proteſtant in religion. This able financier had been choſen in the preceding reign to adjuſt ſome differences between the Eaſt India company and the crown, and had diſcharged the truſt in a manner which had gained him the approbation of both parties. Poſſeſſed of very extraordinary talents, his appointment would have excited no ſurpriſe, had it not been contrary to the conſtant policy of

France,

France, which carefully and uniformly excluded the aliens of her country and faith from the controul of her revenue. It now ſtood forward as a new inſtance of enlargement and liberality of ſentiment, worthy the mind of an enlightened monarch.

In the war between Great Britain and the American colonies, Lewis, by the advice of his miniſter, heartily engaged; he afforded effectual aſſiſtance to the oppreſſed acroſs the Atlantic. The principles of their oppoſition to the mother-country were diſcuſſed in all ways and under all ſhapes; every day and hour produced new arguments in favour of their common liberty. The French officers and ſoldiers who had enliſted under their banner heard their reaſonings, felt the generous flame, and at length became patriots inſtead of mere machines wrought into obedience by the force of ſevere diſcipline. It would be needleſs in this article to repeat the events of the American war, which have already been noticed in our work. In the year 1780 ſeveral new changes took place in the French miniſtry, and the ſame year was rendered memorable by the abolition of the inhuman cuſtom of "putting the queſtion," as it was called, by torture, a cuſtom which had been ſo eſtabliſhed by the practice of ages, that it ſeemed to be an inſeparable part of the conſtitution of the courts of juſtice in France. The king likewiſe, at whoſe ſpecial inſtance the torture had been for ever done away, began, with regard to himſelf, and his own expenditure, to inſtitute an economical reform; he readily and cheerfully ſacrificed his own magnificence to the eaſe of his people, and diſmiſſed at once more than four hundred officers belonging to his court. But notwithſtanding theſe attempts at reform, Lewis was obliged to ſubmit to a diſadvantageous peace, on account of the derangement of the public finances. His own example of prudence and economy introduced no public reformation in the manners and habits of thoſe who were rioting on the labours of the poor and induſtrious. Retrenchment in the expenditure became abſolutely neceſſary: an aſſembly of notables was convoked, and diſmiſſed without effecting any material good. Diſappointed of the advantages which the king had flattered himſelf he would have drawn from this body, he was obliged to recur to the uſual mode of raiſing money by the royal edicts. Meaſures were immediately propoſed to double the poll-tax, and to reſort to other impolitic and unpopular impoſts. The parliament of Paris, however, refuſed to regiſter the edicts; and Lewis was obliged to apply, as the laſt reſort, to his abſolute authority, and, by holding what is called "a bed of juſtice," compelled them to enrol the taxes. The parliament, though defeated, were far from being ſubdued; and on the day after the king had held his bed of juſtice, they entered a formal proteſt againſt the edict; declaring, "that it had been regiſtered againſt their approbation and conſent, by the king's authority alone; that it neither ought nor ſhould have any force; and that the firſt perſon who ſhould preſume to attempt to carry it into execution ſhould be adjudged a traitor, and condemned to the galleys." The authority of the ſovereign was now oppoſed to that of the parliament. Paris was already overwhelmed with ſoldiers; and in a few days after the proteſt had been made and promulgated, a French officer of the guards, with a party of ſoldiers, went at break of day to the houſe of each individual member of the parliament, to ſignify to him the king's command, that he ſhould immediately get into his carriage and proceed to Troyes, a city of Champagne, without writing or ſpeaking to any perſon out of his own houſe before his departure. The orders were all ſerved at the ſame inſtant; and before the citizens of Paris could poſſibly be acquainted with the tranſaction, their magiſtrates and protectors were far on the road to their place of baniſhment. The confidence and attachment of the people roſe in proportion to the ſacrifices which had been made in their behalf. Their murmurs were openly expreſſed in the ſtreets of the capital; and the general diſſatisfaction was augmented by the ſtop that was put to public buſineſs, by the exile of the parliament. The cabinet, at the ſame time, was apparently weak, diſunited, and fluctuating; and continual changes took place in every department of the ſtate. Nor was it only in the capital that the flame of liberty burſt forth: it blazed with equal ſtrength in the provincial parliaments, and extended from the centre to every part of the kingdom. Among other inſtances of this nature, the parliament of Grenoble paſſed a decree againſt "Lettres de cachet," the moſt odious engine of arbitrary power; and declared the execution of them within their juriſdiction, by any perſon, and under whatever authority, to be a capital crime.

Previouſly to the baniſhment of the parliament of Paris, they had declared, that, in their opinion, neither the parliaments, nor any other authority, except that of the three eſtates of the kingdom collectively aſſembled, could warrant the laying of any permanent tax on the people; and they ſtrongly enforced the renewal of thoſe national aſſemblies, which had rendered the reign of Charlemagne ſo great and illuſtrious.

In the year 1789, the ſtates-general were convened for the arrangement of public affairs: they aſſumed the name of the national aſſembly, and among its earlieſt labours was that of forming a new conſtitution. The ſpirit of diſcontent and diſorganization ſeemed to pervade all ranks of the people. They did not wait for leaders of known and tried talents; inſpired with a ſenſe of the wrongs that they and their fathers had long endured from the government, they attacked and deſtroyed what they denominated the great fortreſs of deſpotiſm, the Baſtile. Encouraged by this inſtance of ſucceſs, they proceeded farther, and even reſtrained the actions of the monarch. In a ſhort time, the aſſembly, emboldened by the ſupport given them by the people, proceeded to the abolition of titles, and to the deſtruction of that power which the church had for a long ſeries of years aſſumed. Theſe acts drove from the kingdom a multitude of the higher orders of ſociety, who ſought for the honours of rank and diſtinction in a foreign clime which was denied them at home. Theſe were the emigrants, who for a long time employed all their arts in the various courts of Europe, to induce their reſpective ſovereigns to arm againſt France. The hope of ſucceſs excited ſeveral powers to coaleſce, in order to invade the country. The effect of theſe meaſures rebounded on the head of the monarch, who was ſuſpected of having invited the enemy to make war upon his ſubjects. The firſt ſucceſſes of the allied armies enraged the French almoſt to madneſs, and the neceſſity they were under of defending themſelves inſpired them with an energy which in a ſhort time produced the moſt aſtoniſhing victories. Theſe encouraged the leaders of the public mind to meditate exceſſes, which would otherwiſe ſcarcely have been attempted; and the monarch, foreſeeing the ſtorm, reſolved upon flight, but he was arreſted on his road, and brought back with ignominy amidſt the execrations of the infuriated populace. To avoid the ſentence of abdication he accepted and ratified the conſtitution, before the deputies of France, who were preſent on the occaſion. Different parties were very differently affected by this ill-conducted and unfortunate flight of the king. A republican band had already begun to appear, and during the king's abſence attempts were made to induce the public at large to conſider the royal authority as no neceſſary part of the conſtitution, an idea which, at firſt,

was

was ſcouted by every moderate Frenchman, who had been accuſtomed to believe that the glory of the king was eſſential to the very exiſtence of the nation. The flight of the ſovereign was unqueſtionably a deep laid plan, as well with reſpect to the nobility of France, as with foreign courts who were preparing to take advantage of the approaching event. Many of the chiefs among the ariſtocratic party ſent in reſignations of their ſeats in the national aſſembly. Troops were even levied on the frontiers in the king's name: Bouillé, a great general, emigrated, and afterwards ſent to the aſſembly a furious letter: "You ſhall anſwer," ſays he, "for the lives of the king and queen to all the monarchs of the univerſe. Touch but a ſingle hair of their heads, and not one ſtone ſhall be left upon another in Paris. I know the roads. I will conduct the foreign armies. This letter is but the fore-runner of the manifeſto of the ſovereigns of Europe." A conſiderable calm throughout France followed theſe events, and it might be regarded as in a ſtate of tranquillity: but the calm was deluſive, and in the midſt of it thoſe projects were formed which were afterwards to prove ſo fatal to the peace of the world. Towards the cloſe of the ſummer a convention took place at Pilnitz in Saxony, between the emperor Leopold and the king of Pruſſia. Its object at the time was unknown, but it was gradually developed, and it has generally been underſtood to have been intended for the purpoſe of concluding a league for the invaſion of France, the new modelling of its government, and the partition of ſome of its faireſt provinces. The national aſſembly were not deficient in exertions on their part: they formed a new conſtitution, and on the 13th of September the king announced his acceptance of it. This event was ordered to be notified to all the foreign courts, and the aſſembly decreed a general amneſty with reſpect to the events of the revolution. On the 30th of the ſame month the aſſembly, which had been known under the name of the "Conſtituent aſſembly," diſſolved itſelf, and gave place to the ſucceeding legiſlative body that had been elected according to the rules preſcribed by the new conſtitution.

From this period ſocieties and clubs began to be formed in all parts of the metropolis; but that of the Jacobins, ſo called from the name of the place where the members aſſembled, inſenſibly abſorbed all the reſt, and for ſome conſiderable time dictated the politics of France, and even influenced, if not actually commanded, the deciſions of the legiſlature. Being at length reſolved to extort by violence what they were not able to obtain voluntarily, the Jacobins, in conjunction with the municipality of Paris, collected a large concourſe of people of all deſcriptions, and appeared with cannon before the palace. This commotion was unexpected: the king ordered the gates to be opened, and, to calm the violence of the populace, he accepted and placed on his head the red cap, an emblem of the new principles: they retired appeaſed and apparently ſatisfied. This was in the month of June, and after that, events ſucceeded each other with ſuch rapidity, that it would be fruitleſs in this ſketch to attempt an enumeration of them. The legiſlative aſſembly was quickly diſſolved, and early in Auguſt it was determined to elect a National Convention. On the tenth of that month, the ſovereign was driven from his palace, and the Thuilleries became the ſeat of action; a dreadful battle was fought on the very ſpot from which the royal family had fortunately eſcaped but an hour before: the king's guards were overpowered, and every human being that could be found in the palace, attached to the court, were inſtantly put to death. The royal family had taken refuge in the aſſembly, where for many hours they ſat liſtening to diſcuſſions in which themſelves and office were treated with every mark of contempt and inſult. From this place they were ſent to the old palace of the Temple as priſoners, under a ſtrict guard, and all perſons attached to them were ſeized and committed to different priſons.

On the 20th of September the French national convention aſſembled. It contained men of all characters, orders, and ranks, but the general aſpect of it ſhewed moſt decidedly that the republican party had acquired a vaſt ſuperiority, and on the firſt day of their meeting, Collot d'Herbois, who had formerly been an actor, aſcended the tribune, and propoſed "The eternal abolition of royalty in France." The queſtion was carried by acclamation, and the houſe adjourned. On the next day it was decreed that public acts ſhould be dated by the year of the French republic, and all citizens were declared eligible to all vacant offices and places.

It was now determined to bring the king to trial, and on the 11th of December he was conveyed to the bar of the convention, to hear the charges exhibited againſt him; and though he had no previous intimation reſpecting their nature, he replied to them with clearneſs and preciſion, and with a full conſciouſneſs of his own innocence. The trial came on the 26th, when the king appeared for the laſt time at the bar of the national aſſembly. The diſcuſſion was, however, continued to the 18th of January, when, after a ſitting of thirty-four hours, the puniſhment of death was awarded by the ſmall majority of five. Upon this one of the counſel ſolemnly invoked the aſſembly to conſider by what a ſmall majority the puniſhment of death was pronounced againſt the dethroned monarch. No eloquence could, however, avail; the ſentence was ordered to be carried into execution in twenty-four hours. On the 21ſt of January 1793, the bloody deed was perpetrated, and with Lewis ended the third dynaſty of the kings of France, and a monarchy which had laſted without interruption for the long period of eleven centuries. The queen and the king's ſiſter ſhortly after fell victims to the ſame ferocity. A mere chronological table of events that have occurred in France from that time to the preſent would occupy more ſpace than can be devoted to this article: revolution ſucceeded to revolution, till at length Bonaparte contrived to get himſelf elected a conſul, and then chief conſul, in imitation of the office under the ancient republic of Rome. At firſt this office was to be held for a limited time only, but during that period he contrived to make it not only an office for life, but hereditary in his own family for ever. Not contented with this, he, by degrees, cauſed the people, who had contended for liberty with infinite ſlaughter for many years, to proclaim him emperor, with unlimited powers. Inveſted with this high authority, and having under his controul immenſe armies and a mighty population, he has gone on from victory to victory, till at length he has ſubjugated almoſt the whole continent. The kings of Bavaria, Saxony, and Wirtemberg, have all been raiſed to that high honour ſolely by his influence. On the thrones of Weſtphalia, Holland, and Spain, he has placed three of his own brothers, and on that of Naples, his creature and general, Murat, the late grand duke of Berg. The court of Portugal he has driven for an aſylum to South America, and over the republic of the Seven Iſlands he has placed a preſident. Pruſſia has been ſubdued by the armies of France, and Ruſſia is kept in awe of the ſame power. Over Italy Bonaparte himſelf claims the title and power of ſovereign, as well as emperor of France, with a population of more than thirty millions of people; and in the courſe of the laſt year he annexed the papal territory to his own dominions, and aboliſhed for ever the terrors of the inquiſition. With reſpect to Auſtria, ſhe has

again and again contended with the power of Napoleon, but has always proved unſucceſsful in the arduous conteſt. Her proweſs, however, was not to be deſpiſed by the conqueror, and when he found that he could not completely reduce her to ſubjection, he thought upon other meaſures to effect his purpoſe. With this view, and with the hope of obtaining an heir to his vaſt dominions, he, in the month of December 1809, divorced himſelf from the empreſs Joſephine in the preſence of ſeveral of the crowned heads of Europe, and during the preſent month (April 1810) he has married, with the conſent, real or feigned of all parties, the daughter of the emperor of Auſtria, with whom, of courſe, he has made an alliance of perpetual peace and amity.

Such has been the conduct of the emperor Napoleon Bonaparte, by birth a poor Corſican, but by his fortune or talents he has rendered himſelf the firſt man that has ever lived in the world. To attain this exalted ſituation he has not been very particular in the choice of means to effect his ambitious projects. He has never ſcrupled to reſort to deſpotic meaſures when thoſe were likely beſt to anſwer his ends; but in no inſtance has the tyrant ſhewn itſelf more than in one of his lateſt acts. The French nation in 1789 were contented to ſhed their beſt blood to deſtroy the accurſed baſtile; in March 1810 they have ſeen, without a murmur, their emperor erect eight baſtiles to confine perſons avowedly, "whom it is not convenient to bring to trial or to ſet at liberty." Yes, theſe infernal dungeons are ſcattered about the empire to keep the people in awe of a power, which already they dare not openly oppoſe, and to ſhut the mouths of thoſe from whoſe hands the pen has long ſince dropped. The vile decree indeed, aſſerts, "that many of theſe ſtate priſoners might be condemned by the tribunals to capital puniſhments, but that ſuperior conſiderations oppoſe their being brought to trial; that ſeveral are men accuſtomed to crimes, but who cannot be condemned by our courts, though they have the certainty of their culpability; that ſome belong to different countries, which have been united to France, but that they cannot be tried, becauſe their offences are either political or anterior to the union of theſe ſtates." To ſo low, ſo degrading a ſtate, is perſonal liberty brought in France; how debaſed muſt a people be to ſubmit to ſuch a decree, and under ſuch frivolous pretences! Univerſal Hiſtory. Playfair's and Blair's Chronology. Hiſtoire de France. Gibbon's Hiſtory. Rabaut's Hiſt. of the Revolution, &c.

France is ſituated within the eighth geographical climate. The length of the longeſt day at Paris is of ſixteen hours. Its temperature is, generally ſpeaking, healthy and moderate. The moſt careful meteorological obſervations give for the centre of France an average of 27 degrees of Reaumur's thermometer for the greateſt heat, and ſeven for the leaſt. The greateſt height of mercury in the barometer is 28° 5′ 7″, the leaſt 27° 3′ 3″. The quantity of rain 20° 2′ 4″. There are 164 rainy days. The prevailing winds are the ſouth-weſt and north-eaſterly wind.

In the north of France the greateſt heat is 23° 2′, the leaſt 6° 6′; the greateſt height of mercury in the barometer 28° 8′ 3″, the leaſt 27° 1′ 4″. There are 126 rainy days. The prevailing wind blows from the ſouth-eaſt.

In the eaſt of France the greateſt heat is 24° 3′, the leaſt 9° 5′. The greateſt height in the barometer 27° 10′ 10″, the leaſt 26° 8′ 5″. There are 145 rainy days. The north and ſouth-weſt are the prevailing winds.

In the weſt of France the greateſt heat is 24°, and the leaſt 6°, the average height of mercury in the barometer is 28° 3′. There are 150 rainy days, and the north-eaſt is the prevailing wind.

In the ſouth-eaſt, at Montpellier, the greateſt heat is 28° 1′, the leaſt 3° 7′; the greateſt height of mercury in the barometer 28° 5′ 3″, the leaſt 27° 5′ 5″. The quantity of rain 27° 8′. There are 74 rainy days, and the north and north-eaſt are the prevailing winds.

At Marſeilles the meteorological obſervations of nine ſucceſſive years give an average of 25° 3′ for the greateſt heat, and 3° 1′ for the leaſt. The greateſt height of mercury in the barometer is 28° 7′ 2″, the leaſt 27° 3′ 7″. The quantity of rain is 21° 10′ 2″. There are 57 rainy days. The prevailing winds blow from the ſouth-eaſt and north-weſt.

The ſoil of France varies very much in different parts of that extenſive country. Mr. Arthur Young, in his journey through France in the years 1787, 1788, 1789, and 1790, obſerved ſeven different kinds of ſoil, *viz*:

a, a fat and rich ſoil, prevailing chiefly in the departments of Mont Tonnerre, of the Lys, the Scheldt (l'Eſcaut), the Pas de Calais, the North, the Aiſne, Seine and Marne, Seine, Seine and Oiſe, Eure and Loire, Eure, Lower Seine, Somme, l'Oiſe, Lower Rhine, Aude, Tarn, Lot, Upper Garonne, Hérault, Vendée, Two Sèvres, Loiret, Pô, Marengo, Tanaro, and Seſia.

b. Heath and downs (landes), prevailing in the departments of the Two Nethes, the Roër, Lower Loire, Morbihan, Finiſterre, Côtes du Nord, Ille et Vilaine, Mayenne and Loire, Orne, Calvados, La Manche, Gironde, Dordogne, Lot and Garonne, Arriège, Upper Pyrenees, Lower Pyrenees, Landes, Gers, Aveyron, and Gard.

c. Marl (Terres à craie), prevailing in the departments of the Marne, the Ardennes, Aube, Upper Marne, Loire and Cher, Indre and Loire, Charente, Lower Charente, and Vienne.

d. Gravel (Terres de gravier), prevailing in the departments of the Nièvre, and the Allier.

e. A flinty ſoil (Terres pierreuſes), prevailing in the departments of the Sarre, the Forêts, Rhine and Moſelle, Moſelle, Voſges, Meurthe, Meuſe, Upper Rhine, Côte d'Or, Upper Saône, Doubs, Saône and Loire, Jura, Ain, Yonne, Rhône, Loire, and Jemmapes.

f. A rocky ſoil (Terres de montagnes), prevailing in the departments of the Ourte, of the Sambre and Meuſe, Lower Meuſe, Eaſtern Pyrenees, Lozère, Cantal, Corrèze, Upper Loire, Ardêche, Drôme, Upper Alps, Lower Alps, Maritime Alps, Var, Mouth of the Rhône, Vaucluſe, Puy de Dôme, Mont Blanc, Léman, Iſère, Liamone, Dolo, Stura, and Doire.

g. A ſandy ſoil, prevailing in the departments of the Indre, Cher, Creuſe, Upper Vienne, Sarthe, and Mayenne.

Or, taking the whole ſuperficies of France, without Genoa, Tuſcany, and the former papal dominions at 61,258,782,06 hectares, there may be reckoned,

For arable lands -	33,219,437,40 hectares
Vine lands - -	2,434,365,64.
Woods - -	8,134,716,26.
Meadows - -	3,302,033,92.
Artificial meadows -	3,745,303,84.
Heaths, downs, waſte lands, Rivers, ponds, marſhes, &c.	10,422,925,00.

Before the revolution of 1789, France was divided into thirty-two governments, *viz*. Picardy, Artois, Flandres, Normandy, Iſle de France, Champagne, Lorraine, Alſace, Bretagne, Maine, Anjou, Touraine, Orléanois, Berry, Nivernois, Bourgogne; Franche Comté, Poitou, Aunis,

La

La Marche, Le Bourbonnois, Saintonge et Angoumois, Limoſin, Auvergne, Lyonnois, Dauphiné, Guienne et Gaſcogne, Béarn, Comte de Foix, Rouſſillon, Languedoc, and Provence. Beſides theſe thirty-two governments; which were ſtyled great governments, there were eight leſſer ones of ſmall extent, *viz.* Paris, the Boulonnois in Picardy; the Havre de Grace in Normandy; Saumur, between Anjou, Touraine, and Poitou; Metz and the Pays Meſſin; Verdun, and the Verdunois; Toul and the Toulois, all three ſituated in Lorraine, and known by the name of the three biſhoprics; and laſtly Sedan, between Lorraine and Champagne in the north.

In financial and civil matters, France was divided into twenty generalties for the Pays d'Election, and five for the Pays d'Etat, and eight intendancies, making in all thirty-three financial and civil departments, with only thirty-two intendants, becauſe there was only one intendant for the two generalties of Languedoc.

The eccleſiaſtical diviſions of France, at the ſame period, were eighteen archbiſhoprics and 112 biſhoprics, beſides the archbiſhopric of Avignon for the comtat Venaiſſin, which belonged to the pope, and which counted three biſhoprics. There were alſo ſix biſhops ſuffragans of two German archbiſhops, *viz.* Straſburg ſuffragan of Mentz or Mayence, and Metz; Toul, Verdun, Nancy, and Saint Diez ſuffragans of Treves. The number of pariſhes in France at that time was 40,000. There were 800 convents of monks, 281 nunneries, and 679 chapters.

The decree of the national aſſembly of the 12th of July 1790, reduced the archbiſhoprics to 10, and the biſhoprics to 83. But in conformity with the concordat concluded on the 25th of July 1801, between the French conſular government, and the pope Pius VII., a new eccleſiaſtical diviſion was adopted by the law of the eighth of April 1802, which eſtabliſhed 10 archbiſhops and 51 biſhops, *viz.* 1. The archbiſhop of Paris, who has under him the biſhops of Troyes, Amiens, Soiſſons, Arras, Cambray, Verſailles, Meaux, and Orleans. 2. The archbiſhop of Malines, who ſuperintends the biſhoprics of Namur, Tournay, Aix la Chapelle, Treves, Gand, Liege, and Mayence. 3. The archbiſhop of Beſançon, who has under him the biſhops of Autun, Metz, Straſburg, Nancy, Dijon. 4. The archbiſhop of Lyons, who ſuperintends the biſhoprics of Mende, Grenoble, Valence, and Chambéry. 5. The archbiſhop of Aix, who has under him the biſhops of Nice, Avignon, Ajaccio, Digne, and Vintimille in the principality of Piombino annexed to France. 6. The archbiſhop of Toulouſe, who ſuperintends the biſhoprics of Cahors, Montpellier, Carcaſſonne, Agen, and Bayonne. 7. The archbiſhop of Bourdeaux, who has under him the biſhops of Poitiers, La Rochelle, and Angoulême. 8. The archbiſhop of Bourges, who ſuperintends the biſhoprics of Clermont, Saint Flour, and Limoges. 9. The archbiſhop of Tours, who has under him the biſhops of Le Mans, Angers, Nantes, Rennes, Vannes, Saint Brieux, and Quimper. 10. The archbiſhop of Rouen, who ſuperintends the biſhoprics of Coutances, Bayeux, Séez, and Evreux. To theſe muſt be added for the countries that have ſince been annexed to France; 11. The archbiſhop of Turin, who has under him the biſhops of Acqui, Aſti, Caſal, Ivrée, Mondovi, Saluces, Verceil. 12. The archbiſhop of Genoa with the biſhops of Albenga, Borgo ſan Donino, Brugnetto, Parma, Plaiſance, Sarzanne, Savonne, and Pontremoli; and, 13. The archbiſhop of Rome.

The firſt national aſſembly of France, by its decrees of the 15th of January, and 16th and 26th of February 1790, divided France into 83 departments, ſubdivided into 544 diſtricts. But the conqueſts of France having conſiderably increaſed its territory, the number of departments was extended to 102, by a law of the year 1800, and that of diſtricts reduced to 417; when a prefect was placed at the head of the civil adminiſtration of each department, and a ſub-prefect eſtabliſhed for every diſtrict.

In 1807 the number of departments, owing to the annexation of the Ligurian or Genoeſe republic and other territories, was 110, *viz.* 1, Lower Alps; 2, Mouth of the Rhône; 3, Var; 4, Vaucluſe; 5, Upper Alps; 6, Drôme; 7, Iſere; 8, Doubs; 9, Jura; 10, Upper Saône; 11, Lower Rhine; 12, Upper Rhine; 13, Meurthe; 14, Meuſe; 15, Moſelle; 16, Voſges; 17, Ardennes; 18, Aube; 19, Marne; 20, Upper Marne; 21, North; 22, Pas de Calais; 23, Aiſne; 24, Oiſe; 25, Seine; 26, Seine and Oiſe; 27, Somme; 28, Seine and Marne; 29, Calvados; 30, Eure; 31, Manche; 32, Orne; 33, Lower Seine; 34, Côtes du Nord; 35, Finiſtère; 36, Ille and Vilaine; 37, Lower Loire; 38, Morbihan; 39, Indre and Loire; 40, Mayenne; 41, Mayenne and Loire; 42, Sarthe; 43, Two Sèvres; 44, Vendée; 45, Vienne; 46, Eure and Loire; 47, Loire and Cher; 48, Loiret; 49, Indre; 50, Cher; 51, Nièvre; 52, Ain; 53, Côte d'Or; 54, Yonne; 55, Saône and Loire; 56, Loire; 57, Rhône; 58, Allier; 59, Corrèze; 60, Creuſe; 61, Upper Vienne; 62, Charente; 63, Lower Charente; 64, Dordogne; 65, Gironde; 66, Landes; 67, Lot and Garonne; 68, Gers; 69, Lot; 70, Aveyron; 71, Lower Pyrenees; 72, Upper Pyrenees; 73, Arriège; 74, Eaſtern Pyrenees; 75, Ardêche; 76, Aude; 77, Gard; 78, Upper Garonne; 79, Herault; 80, Lozère; 81, Tarn; 82, Cantal; 83, Upper Loire; 84, Puy de Dôme; 85, Golo; 86, Liamone; 87, Mont Blanc; 88, Maritime Alps; 89, Leman; 90, Dyle; 91, Eſcaut (Scheldt); 92, Forêts; 93, Jemmappe; 94, Lys; 95, Lower Meuſe; 96, Two Nèthes; 97, Ourthe; 98, Sambre and Meuſe; 99, Roër; 100, Sarre; 101, Rhine and Moſelle; 102, Mont Tonnerre; 103, The Apennines; 104, Doire; 105, Genoa; 106, Marengo; 107, Montenotte; 108, Po; 109, Seſia; 110, Stura. To which muſt be added for Parma and Plaiſance, Tuſcany, the papal dominions, and a new department formed out of different cantons of the departments of Aveyron, Upper Garonne, Gers, Lot, and Lot and Garonne by the ſenatus conſultum of the 2d of November 1808, the departments of, 111, Tarn and Garonne; 112, Taro; 113, Arno; 114, Mediterranean; 115, Ombrone; 116, Rome; and, 117, Traſimene.

The military diviſions of France are twenty-nine, each of which is commanded by a general of diviſion, *viz.*; 1, Paris; 2, Mezières; 3, Metz; 4, Nancy; 5, Straſburg; 6, Beſançon; 7, Grenoble; 8, Marſeilles; 9, Montpellier; 10, Toulouſe; 11, Bourdeaux; 12, Nantes; 13, Rennes; 14, Caen; 15, Rouen; 16, Lille; 17, Dijon; 18, Lyons; 19, Périgueux; 20, Bourges; 21, Tours; 22, Baſtia; 23, Bruſſels; 24, Liège; 25, Mayence; 26, Turin; 27, Genoa; 28, Florence; 29, Rome.

Beſides the important natural advantages of a large extent of country, enjoying an extenſive ſea-coaſt on three different ſeas, of a highly centrical and commercial ſituation, of limits fixed by the boldeſt features of nature, three chains of high mountains, three ſeas, and a large river; of a moſt favourable climate, excellent ſoil, and advantageous topographical diviſions; France enjoys the advantage of being irrigated by ſeven great rivers, the Rhine, the Rhône, the Maes, the Scheldt, the Seine, the Loire, and the Garonne, and interſected by more than 7000 leſſer ones. Its principal lakes are, 1, the lake of Geneva, in the department of the Léman, now called lac Leman, about twenty-nine leagues long and four leagues broad in its greateſt breadth; 2, the lake of

Annecy, in the department of Mont Blanc, four leagues long; 3, the lake of Bouget, in the ſame department; and, 4, the lake of Allègre, at the top of a mountain in the department of the Puy de Dôme.

Of the mountains of France, the moſt remarkable are that chain of the Alps which croſſes the three departments of the Maritime Alps, Lower Alps, and Upper Alps, afterwards ſtretches to the north, and divides France from the kingdom of Italy and Switzerland. Some of the ſummits of the Alps are 2700 fathoms, (toiſes,) or 5260 metres above the level of the ſea. A leſs elevated branch of the Alps begins in the department of the Leman, ſtretches into the departments of the Jura, Upper Saône, Doubs, Upper Rhine, Voſges, Lower Rhine, Meurthe, Moſelle, Sarre, and Mont Tonnerre. A third branch riſes in the department of the Drôme, croſſes the departments of the Ardêche, Loire, Rhône, Saône and Loire, and Côte d'Or as far as Dijon. It has alſo ſome ramifications in the departments of the Cantal and Puy de Dôme, extends itſelf to the ſouth-weſt through the departments of the Upper Loire, Lozère, Gard, Aude, Hérault, Tarn, Upper Garonne, and Arriège as far as the Pyrenees, which form a natural boundary between France and Spain. This chain of the Pyrenees ſtretches to the ſouth of France, from the port of Vendres on the coaſt of the Mediterranean ſea to the Atlantic ocean on the coaſts of Spain. Its greateſt breadth is 40 leagues, and its higheſt ſummit 1442 fathoms, (toiſes,) or 2808 metres above the level of the ſea.

France abounds in woods and foreſts. A committee of the firſt national aſſembly ſtated the whole extent of territory covered with wood at 13,100,691 arpens, of 100 perches of 28 ſquare feet French each. Mr. Neckar and Mr. Arthur Young have both conſiderably over-rated it by ſtating it at 22,289,016 arpens. This eſtimate may however be tolerably correct now, with the addition of the conquered countries.

The roads of France are generally ſpacious, ſtraight, well paved, planted on both ſides with cheſnut-trees, poplars, walnut, mulberry, or other fruit-trees. There are twenty-eight principal roads from Paris to the boundaries of France. Turnpike-gates and tolls have been eſtabliſhed ſince the revolution, at the diſtance of five kiliometres from each other. The duty is 15 centimes, about 1½*d.* ſterling for every coach-horſe, and 10 centimes, about 1*d.* for a ſaddle-horſe. The wheels of heavy waggons are nine inches three lines broad. They are allowed to carry only a certain weight, which varies during the five winter and the ſeven ſummer months.

Of the numerous canals of France, the moſt conſiderable are, 1, the ſouthern canal, better known by the name of the Canal du Languedoc. It forms a communication between the Atlantic ocean and the Mediterranean ſea; 2, the canal of Briare and Orléans, thus called becauſe it forms a communication between the Seine and Loire, which begins at Orléans and ends at Briare; 3, the eaſtern canal, known by the name of Canal de la Côte d'Or, and forming a communication between the Yonne and Saône; 4, the canal of the center, formerly called Canal du Charolais, which forms a communication between the Saône and Loire.

France has no dependencies in Europe but the kingdom of Italy, which is, however, to loſe its connection with the French empire after the demiſe of the preſent emperor Napoleon I., who is at the ſame time king of *Italy* (which ſee). Still the ſtates of the Confederation of the Rhine, and the kingdoms of Naples and Holland, as well as the Helvetic union, of which the French emperor is the mediator, are little better than dependencies or vaſſal ſtates, forced to move in the direction to which they are impelled by France.

But, if France has been a gainer in its own immediate neighbourhood, it has experienced ſevere loſſes in its diſtant colonies. The fate of its moſt important Weſt India iſlands has already been detailed under the article *St. Domingo* (which ſee). All the other French Weſt India iſlands, which were acknowledged as belonging to France by the treaty of Amiens of the 25th of March 1802, have been conquered by the Engliſh in the courſe of the war which broke out in 1803, and which is ſtill (1810) raging. They were *La Martinique*, *Guadaloupe*, *St. Lucia*, *Tobago*, *Marie Galante*, *La Deſirade*, *Les Saintes*, (which ſee). Cayenne, on the South American continent, has ſhared the ſame fate. The poſſeſſion of the two iſlands in the Eaſt Indian ſeas, Mauritius and Bourbon, called by the French Iſles de France, and de la Réunion, is not leſs precarious, the latter having been recently invaded by the Engliſh, and the former being at this moment cloſely blockaded. The other commercial eſtabliſhments of the French in the Eaſt Indies and on the African coaſt were never of any great importance, and have dwindled into complete inſignificance, through the loſs of their foreign commerce in general, and of their ſugar colonies in particular, which were ſupplied with negroes from the Guinea coaſt. See INDIES, and NEGROE, or SLAVE *Trade*.

The fiſheries of France have alſo materially ſuffered from the war with England. The herring fiſhery was already on the decline before the revolution, and is now almoſt annihilated. In the ſhort interval of peace in 1802 it produced

49,550	barrels of	ſalt herrings
6,000	-	freſh
12,000	-	red
making in all 67,550		barrels.

The mackarel fiſhery, which was moſt flouriſhing in 1785, is in the ſame predicament. Oyſters are in abundance at Granville, Dieppe, and Cancale. During the ſhort interval of peace in 1802, 188 Engliſh veſſels loaded at Cancale 119,473,000 oyſters, worth 179,209 French livres. Paris conſumes about twelve millions of oyſters annually. There is a coral fiſhery in the Mediterranean. The coral is poliſhed and wrought at Marſeilles. It uſed to be employed moſtly in the African trade. The commerce of anchovies in the Mediterranean ſea is ſtill conſiderable. They are pickled at Fréjus, St. Tropez, and Cannes. The ſalt is coloured red with ochre. Eels are alſo ſalted for exportation. There is a great abundance of all ſorts of fiſh in all the rivers of France, and in ſome very extenſive fiſhponds, ſuch as the Etang de Villers in the department of the Cher, which is ſix leagues in circumference, and the Etang de l'Indre in the department of the Meurthe, which is four leagues in circumference.

Situated nearly in the centre of Europe, France owes to its ſoil, and to the excellence of its climate, the advantage of rearing alike the plants of the moſt ſouthern countries of Europe, and thoſe which ſucceed more particularly in the north. In the eaſtern Pyrenees the vine is cultivated with as much ſucceſs as in Spain. Silk-worms are reared in the ſouth of France with as much ſucceſs as in Italy, and the olive oil of Aix is preferred all over Europe to that of Genoa and Sicily. Though the agriculture of France cannot be praiſed as good, it yet is amply adequate to furniſh the country with all the objects of firſt neceſſity, food, cloathing, and ſhelter againſt the inclemencies of the weather.

Among the vegetable productions of France, the moſt conſiderable are,

1. Corn, under the general denomination of which are compriſed

comprised wheat, rye, barley, and oats. Its annual produce, before the revolution, was rated

by Vauban at	59,175,000	{ fétiers of 12 Paris buſhels, or 240lb. weight.
by Queſnay at	45,000,000	
by the Abbé d'Expilly at	78,473,380	
by Lavoiſier at	50,000,000	
by Mr. Arthur Young at	75,000,000	
	307,648,380	

the average of which ſum gives 61,519,672 fétiers.

The price of wheat generally varies from 25 to 35 French livres the fétier.

2. Wine. Before the revolution of 1789, France, according to Mr. Arthur Young, cultivated the vine on an extent which conſtituted nearly the twenty-ſixth part of its territory, and grapes formed the ſixth part of its produce. Of 130 millions of acres, five millions were covered with vines, which, at the average produce of 175 French livres per acre, yielded 875 millions. The ſame line of demarcation which that intelligent agriculturiſt traced at that time for the growth of the vine is ſtill correct. France has not changed in that reſpect ſince 1787, and is not likely to change. The annual average produce may be eſtimated at 15,000,000 muids of Paris, of 144 quarts each, or 540 millions of Engliſh gallons. The beſt French wines are thoſe of Burgundy, Champagne, Bourdeaux, Anjou, Orléans, and Poitou.

In the beginning of the laſt century France exported, upon an average of five years, from the year 1720 to 1725, annually, wine to the amount of 20,880,200 French livres.

In 1778 the exportation amounted to	24,570,170	——
In 1788 - - -	33,032,100	——

Of brandy, the exportation in the beginning of the laſt century amounted annually to 5,852,900 livres.

In 1778 - - -	4,660,221	—
In 1784 - - -	11,360,200	—
In 1787 - - -	14,689,600	—
In 1788 - - -	14,657,300	—

Of vinegar, the exportation in the beginning of the laſt century amounted annually to 34,400 livres.

In 1778 - - -	141,893	—
In 1784 - - -	124,400	—
In 1787 - - -	130,900	—
In 1788 - - -	201,700	—

3. Hemp and flax, but neither in ſufficient abundance for its own conſumption.

4. Rape and poppy ſeed, which furniſh excellent lamp-oil, chiefly in the northern departments.

5. Indian corn and buck-wheat.

6. Madder, tobacco, and hops.

7. All ſorts of pulſes, roots, pot-herbs, greens, graſſes, and an immenſe variety of medicinal plants.

8. All ſorts of the fineſt fruits, as lemons, oranges, cheſnuts, olives, &c.

Attempts have alſo recently been made at introducing the culture of indigo and cotton. A report of the municipality of Lille, in the department of Vaucluſe, confirmed the ſucceſs of a plantation of indigo upon a large ſcale, in an open field, on part of the eſtate of Mr. Icard de Bataglini, and on ſome of the heaths (landes) of France. Mr. Louis Dupoy, a coloniſt of St. Domingo, at preſent comptroller of the cuſtoms at Dax, has ſucceſsfully introduced the culture of cotton; he provided himſelf with ſeeds proper for the experiment in Louiſiana. Very fine cotton has been produced, and the pods have attained perfect maturity.

Among the principal animal productions of France are,

1. Horſes, which have, however, conſiderably degenerated ſince 1789; the public ſheds having long been neglected, a vaſt conſumption occaſioned by continual wars, and a wilful deterioration introduced by the farmers to ſave their cattle from the revolutionary requiſitions. In the year 1802 the total number was,

Of plough horſes - -	1,500,000
Horſes kept at Paris -	35,100
In all the other towns -	200,000
In the armies - -	100,000
	1,835,100

2. Oxen and cows, *viz.*

Oxen employed in huſbandry -	3,208,000
—— feeding - - -	404,500
Young oxen - - - -	1,456,000
Cows - - - - -	1,016,000
	6,084,500

3. Sheep, which are improved from the Spaniſh flocks of Rambouillet, Perpignan, Croiſſy ſur Seine, Dun ſur Auroux, and Montbar. Their number in 1802 was 30,307,728, one million of which were in the moſt improving condition. The common fleeces weigh 3lb. each; thoſe of the improved breed from 6 to 8lb. The total of the wool they yield may be rated at 106,770,048lb. This ſupply is, however, inſufficient for the manufactures when they are in full activity. There are alſo great numbers of goats, mules, aſſes, and hogs. Poultry is uncommonly abundant. The average price of a good fowl is 10*d.*; of a pigeon 3*d.*; of a duck 1*s.*; a gooſe 2*s.*; a turkey 2*s.* 9*d.* Bees are carefully reared. The beſt honey is that of Narbonne.

France is very rich in mineral productions. They have been conſiderably increaſed by the diſtreſs to which it was reduced in 1792, 1793, and 1794, by the coalition of all the great powers of Europe.

1. Of the pure metals iron is the moſt abundant. Two thouſand forges ſupply the wants of the country, which before the revolution was obliged to import iron to the annual value of from 11 to 12 millions of French livres.

The principal copper mines are in the departments of the Rhône, the Upper Pyrenees, and the Upper Alps.

Of the few lead mines that are worked moſt yield ſilver at the ſame time.

The principal mines of mercury and calamine are in the departments of the Ourte and Roër. Antimony and manganeſe are in great abundance.

2. Of metallic ſalts France has green, white, and blue copperas; verdigris chiefly at Montpellier; alum, Epſom-ſalt, in the neighbourhood of Liège; marine ſalt (ſoud muriatée) ſaltpetre, and ſal ammoniac.

3. Of the mineral acids France has the moſt important, *viz.* the ſulphuric acid, or oil of vitriol, the nitric acid, or aqua fortis, and the muriatic oxygenated acid.

4. Of the combuſtible minerals France has pit-coal in abundance, chiefly in the departments of Jemmappe, Sarre, Lower Meuſe, Roër, North, Calvados, Loire, Upper Loire, Hérault, and Tarn. Some anthracites in the Pyrenees and in the department of the Rhône. Jet in the departments of the Aude, Gard, and Ardêche. Solid bitumen,

called aſphaltum, chiefly in the departments of Ain and the Lower Rhine. Glutinous bitumen, called piſaſphaltus, in the department of Puy de Dôme. Liquid bitumen, called naphtha and petroleum, in the departments of the Hérault and the Lower Pyrenees. Turf chiefly in the departments of the Somme, North, and Pas de Calais.

All ſorts of earths and ſands uſed in manufactures, as kaolin, or porcelain earth, arenaceous quartz, puzzolane, &c. and all kinds of ſtony ſubſtances employed in the arts, abound in France, from the maſſy rock that forms the ſtately column, to the gem that ſparkles on the neck of beauty.

The principal manufactures of France are thoſe

1. Of linen cloth, in the departments formed out of the ancient provinces of Normandy, Picardy, Flanders, Hainaut, Cambréſis, Bretagne, Maine, Dauphiné, Auvergne, Beaujolais, Gaſcogne, and Anjou. Before the revolution France exported linen cloth to the amount of from 12 to 13 millions of livres.

2. Of lawn and cambric, the exportation of which amounted to about ſix millions of livres.

3. Of thread lace, chiefly at Bruſſels, Malines, Valenciennes, Dieppe, and Le Puy.

4. Of ſail cloth, chiefly at Rennes, Angers, Agen, Marſeilles, Mont de Marſan, &c.

5. Of cables and ropes at Breſt, Rochefort, Toulon, Abbeville, Dunkirk, and Havre de Grace.

6. Of printed calico, ſhawls, ſiamoiſes, &c. at Rouen, Troyes, Darnetal near Rouen, Beauvais, Langres, Crevelt.

7. Of muſlin at Rouen, Niſmes, Geneva, Béziers, Rheims.

8. Of dimity and fuſtian of a ſuperior quality at Alençon, Lyons, Troyes, Bruſſels, and Toulouſe.

9. Of writing and printing paper at Annonay, Montargis, Eſſonne, Courtalin, Rambervilliers, Dynoſée, Arches, Archettes, Docelles, St. Breſſon near Luxeuil, Beſançon, Ornant, Villafant, Arbois. Paper-hangings at Paris in the manufactures of Réveillon, Arthur, and others. They are exported to Italy, Holland, Germany, and as far as Ruſſia. Before the revolution the paper manufactured in France amounted to the annual value of 8 millions, 1,350,000 livres of which were exported to foreign countries, and 350,000 livres to the French colonies. Paris alone conſumes annually 305,000 reams.

10. Of ſoap of the firſt quality at Marſeilles, inferior ſoap at Toulon, Bourdeaux, Rouen, Nice, Lille, Abbeville, Amiens, St. Quentin. The amount of this manufacture is 60 millions, two of which only are exported.

11. Of ſtarch, the principal manufacture of which is at Paris.

12. Of tobacco and ſnuff, *viz.* 22,000 cwt. of ſnuff, and 2000 cwt. of tobacco. Every individual in France is ſuppoſed to uſe on the average 12 ounces of ſnuff annually.

13. Of fine woollen cloth, chiefly at Sédan, Abbeville, Louviers, Elbeuf, Rouen, Darnetal, les Andélys, Vienne, and Montauban. Common woollen cloth is made at Chateauroux, Iſſoudun, Aubigny, Romorautin, St. Aignan, Roybon, Creſt, Saillans, Romano, Grenoble, Valence, Valogne, Amboiſe, Niort, Aix, Apt, the Cévennes, &c. Woollen ſtuffs, as camelots, baracans, ſerges, calamancoes, and pluſh, are are alſo manufactured in great quantities. In 1784 France exported

Cloth amounting in value to -	15,530,900 livres.
Stuffs - - - - -	7,600,600
Pluſh, &c. - - - -	4,425,100.

The exportation of the two firſt articles in 1787 amounted to 14,242,400, and 5,615,800 livres. The produce of the whole woollen manufacture was rated in 1789 at 140 millions annually.

14. Of ſilks, chiefly at Lyons, Tours, Niſmes, Paris, and Marſeilles. This manufacture has, however, declined ſince the revolution. In 1789 its produce was rated at 125 millions, and it employed from 28 to 30,000 looms. The ſilk-worms reared in France yield 15,000,000lbs. of ſilk annually; but this quantity is not ſufficient for the manufacture.

15. Of hats chiefly at Lyons, Rouen, and Paris.

16. Of watches at Paris, Geneva, Cluſe, and Carouges. The number of watches conſumed annually in France before the revolution was ſuppoſed to amount to 200,000.

17. Of jewellery, which at Paris and Lyons only employed nearly 70,000 workmen before the revolution.

18. Of cannons and all ſorts of arms. This manufacture has been conſiderably improved, and attracts the particular attention of government.

19. Of china, (chiefly at Sèvres,) glaſs, and mirrors. This manufacture is alſo carried to a high degree of perfection, and the ſame may be aſſerted of the manufacture.

20. Of carpets and tapeſtry. The tapeſtry manufactures at La Savonnerie and Beauvais, though not equal to the celebrated manufacture of the Gobelins at Paris, are very little inferior to it.

The inland trade of France, like that of all extenſive, populous, and induſtrious countries, was at all times far ſuperior to its foreign commerce. It reſults from the conſumption of the produce of its own fiſheries, mines, agriculture, and manufactures, and its circulation from one province to the other. The foreign commerce of France, compriſing its exports of the produce of French induſtry and French colonies, and the importation of foreign commodities, is almoſt annihilated by the war with England. In 1787 the exportation amounted in all to 542,604,000 livres, of which 311,472,000 livres were the raw produce of the ſoil, mines, and fiſheries, and 231,132,000 the produce of French manufactures. In 1800 it amounted only to 271,564,000 livres in all, *viz.*

Raw produce and wines - - -	87,562,000
Metals, minerals - - - -	4,530,000
Manufactured goods - - -	140,854,000
Divers other articles - - -	38,618,000

The imports of France, upon an average of the years 1785, 1786, and 1787, were 611,008,200 livres. But Mr. Roland, in his report to the convention in 1792, ſtated the average imports of France to amount to no more than 319 millions. In 1800 they amounted to 325,116,000 livres.

According to Mr. Neckar the balance of commerce in 1784 was 70 millions of French livres in favour of France. He calculated the imports at 230 millions annually, and the exports at about 300 millions. But from the ſtate of the French commerce in 1787, which Mr. Arnould has analyſed with much care, it appears that

the importation, amounting to	611,008,200 livres, and
the exportation only to -	542,604,000
there was a balance of -	684,042,200 livres

againſt France. And in the year 1800, when

the importation amounted to	325,116,000 livres, and
the exportation only to -	271,564,000
there was ſtill an unfavourable balance of - -	53,552,000 livres.

A very

FRANCE.

A very inconſiderable part of the French trade is carried on in French ſhips. Colbert was the firſt miniſter of ſtate in France who directed his particular attention to the encouragement of the French merchant navy, which in the year 1669 did not count above 600 veſſels; and it is ſuppoſed that in the beginning of the 18th century this number had not been increaſed to much beyond 800 veſſels of from 100 to 250 tons. From that period, however, to the revolution of 1789, the French merchant navy had been conſiderably improved and greatly encouraged. Yet even at that time, though the French trade in the Baltic employed 705 veſſels, there were ſcarcely 100 French among them; and in 1788 all the ports of France had not above 1000 merchantmen of the average of 250 tons employed in long voyages to both the Indies, and in the cod and whale fiſheries. The exports to different countries in Europe took up about the ſame time 580,000 tons, of which a little better than a fourth, or 152,000 tons, were French.

From an official report made by Roland to the national convention in 1793, it appears that in the year 1792 there entered inwards into the ports of France 7607 veſſels, amounting in all to 639,235 tons; of which

1823	veſſels, or	147,821	tons, were	French,
1940	- -	145,012	- -	Engliſh,
3844	- -	346,402	- -	belonging to

other nations. And in the ſame year there cleared outwards 8618 veſſels, amounting in all to 544,935 tons, of which

1940	veſſels, or	147,410	tons, were	French,
3111	- -	90,662	- -	Engliſh, and
3567	- -	306,863	- -	belonging to ſeveral other nations.

The money in circulation in France in the year 1789 was ſtated by Mr. Bonvallet Deſbroſſes in his "Tableau des Richeſſes de la France," at 2,474,254,960 livres, 350 millions of which conſiſted in notes of the Caiſſe d'Eſcompte.

In the maritime departments the circulating medium amounted to 1,053,838,350 livres, and the buſineſs tranſacted by its means to 4,485,600,000 livres. In thoſe on the boundaries of France the money in circulation amounted only to 385,227,000 livres, and the buſineſs done with it to 453,600,000. In the central departments the circulating medium was 1,035,189,600 livres, and the trade carried on with it amounted to 11,874,600,000 livres; this more animated circulation ariſing entirely from the trade of the metropolis.

The ſtandard coin of France is a piece of ſilver of the weight of five grammes, or five times 18 $\frac{8\,4\,1}{1\,0\,0\,0}$ grains, containing a tenth of alloy and $\frac{9}{10}$ of pure ſilver, and very nearly the 24th part of the pound ſterling's metallic value. It is called a franc, and ſubdivided into décimes and centimes. Its value is to that of the ancient livre Tournois in the proportion of 81 to 80, or as it contains $\frac{9}{10}$ of fine ſilver, it is equal to 1 livre, 3 deniers. There are pieces of 5 francs, 2 francs, $\frac{3}{4}$, $\frac{1}{2}$, and $\frac{1}{4}$ franc. The decime is the tenth part of a franc. It is equal to 2 ſous, $\frac{3}{1}$ deniers. The centime is the hundredth part of a franc, equal to 2 $\frac{4\,3}{1\,0\,0}$ denier. The gold coins, like the ſilver coin, contain $\frac{1}{10}$ of alloy, and $\frac{9}{10}$ of pure metal. They are called Napoleons d'or, or octogrammes. An octogramme of gold is worth 25 francs. The kiliogramme of gold, which is the premium awarded by the national inſtitute for the beſt anſwer to its prize queſtions, is valued at 3375 francs. The towns which have mints where money is coined are diſtinguiſhed by a particular letter on the coin. Paris has the letter A; Perpignan, Q; Bayonne, L; Bourdeaux, K; Nantes, T; Lille, W; Straſburg, BB; Lyons, D; Geneva, G; Marſeilles, MM; Turin, C.

The preſent bank of France was eſtabliſhed in 1801, with a capital ſtock of thirty millions of francs in hard caſh, made up of thirty thouſand ſhares of a thouſand francs each, which makes each ſhare equal to 1012 livres Tournois. The law of the 22d of April, 1806, inſures to this bank an excluſive privilege of forty years, to be reckoned from the 22d of September, 1803, for iſſuing notes payable to the bearer and at ſight. Its operations conſiſt in diſcounting, (but only twice in the week, Mondays and Thurſdays,) keeping the caſh of public eſtabliſhments and private individuals, and receiving depoſits of ſums not below fifty francs, for which it gives recognizances bearing intereſt, and made payable either to the bearer or to order. Its general aſſembly is compoſed of 200 holders each of five ſhares or above, who elect fifteen directors and three cenſors. Both the directors and cenſors muſt be holders of at leaſt thirty ſhares. Three of the directors and one of the cenſors go out annually by rotation. The general aſſembly meets once in the year to audit the accounts. The dividend is paid every ſix months. The firſt dividend was of $9\frac{1}{2}$ *per cent.* or 95 francs *per* ſhare: but 5 *per cent.* only were paid, and $4\frac{1}{2}$ *per cent.* were reſerved for leſs favourable times, when the dividends might be under 5 *per cent.*

After many fruitleſs attempts by almoſt all the rulers of France from Charlemagne down to Louis XIV., France, during its ſhort-lived republican conſtitution, ſucceeded in eſtabliſhing uniform weights and meaſures upon the following ſimple plan. The French fundamental, elementary, or ſtandard meaſure, is connected with the dimenſions of the terreſtrial globe. This meaſure, which they call metre, or méſure par excellence, from the Greek μετρον, is the ten millionth part of a quarter of the terreſtrial meridian, that is to ſay, of the diſtance from the equator to the pole. It is equal to 3 feet 11 lines $\frac{4\,4}{1\,0\,0}$.

The are ſerves to meaſure the ſurface of the ſoil in the ſame manner as the ancient arpent. It is equal to 100 ſquare metres, or 948 $\frac{3\,1}{1\,0\,0}$ ſquare feet.

The ſtere is equal to a cubic metre, or $\frac{2\,0\,2\,7}{1\,0\,0\,0\,0}$ cubic feet.

The litre is the meaſure of capacity. It is equal to a cubic decimetre, or 50 $\frac{4\,6}{1\,0\,0}$ cubic inches, or one-twentieth of the former pint of Paris.

The gramme marks the weight. It is equal to the weight of a cubic centimetre of diſtilled water, and weighs 18 $\frac{3\,4\,1}{1\,0\,0\,0}$ grains.

Theſe five primitive meaſures are ſucceſſively multiplied or ſubdivided by ten, in order to form the greater or ſmaller meaſures by analogy to the decimal ſyſtem of arithmetic, which is almoſt univerſally adopted in Europe. The three diviſors are deci, centi, and milli, expreſſing the tenth, hundredth, or thouſandth part: thus, decimetre is the tenth part of the metre, deciare the tenth part of the are, deciſtere the tenth part of the ſtere, decilitre the tenth part of the litre, and decigramme the tenth part of the gramme. The four multiplicators are deca, hecto, kilio, and myria, denoting ten times, hundred times, thouſand times, and ten thouſand times, the primitive meaſure or weight; thus the decametre is ten metres, the hectare hundred ares, the kiliolitre a thouſand litres, the myriagramme ten thouſand grammes, or 20lb. 7 ounces, 58 grains.

That France has not yet recovered its former degree of proſperity may be inferred from the price of land, which is cheap, and the intereſt of money, which is very high. Mr. Pinkney, who travelled through the ſouth of France in

1807 and 1808, reports, that an eſtate of eleven hundred acres, ſeven hundred of which were in culture, the remainder wood and heath, was offered for ſale for leſs than eight thouſand pounds ſterling. The manſion-houſe was in ruin beyond the poſſibility of repair; but the land, under proper cultivation, would have paid 25 *per cent.* on the purchaſe money. There is no law prohibitory of uſury in the code Napoleon; the money market, like that of all other commodities, is left to find its own level.

But although the food, dreſs, and accommodations of the inhabitants of France, have not been improved ſince the revolution, their individual happineſs does not appear to have been materially impaired. Sunday is ſtill a day of feſtivity and a holiday. They ſing and dance, and frequent the theatres. The arts of painting, ſtatuary, architecture, muſic, and dancing, are held in high eſtimation, and foſtered with particular care. Seventeen of the principal towns of France have public galleries of pictures and ſtatues, called muſeums, and the central muſeum at Paris contains above one thouſand paintings, each of which would be deemed a maſterpiece in the collection of a private individual. The moſt eminent living painters of France are Vien, David, Regnault, Vincent, Greuze, Gérard, Girodet, Guerin, Hennequin, Ménageot, Taunay, &c. The moſt eminent ſtatuaries, Pajore, Moitte, Julien, Roland, Houdon, Dejoux, Foucou, Chaudet, Stouf, Boichot, &c. The beſt French architects are David Ledoy, Clériſſeau, Gondouin, who built the Ecole de Chirurgie at Paris, Chalgrin, Le Grand, Molinos, Raymond, Percier, the younger Moreau, Le Doux, Brongniard, &c. The moſt eminent muſical compoſers in France are Grétry, Monſigny, Martiny, Daleyrac, Méhul, Goſſec, Le Sueur, Langlé, Catel, Boyeldieu, Champein, Pleyel, Steibelt, Adam, Kalkbrenner, Kreutzer, Bruni, &c. The love of the arts is particularly encouraged by the fondneſs of the French for theatrical repreſentations, in which all the arts combine for the amuſement of the ſpectators. There is not a town of 30 or 40,000 inhabitants that has not a theatre, in which plays are performed almoſt every evening from one end of the year to the other.

The principal amuſement of which all the claſſes of Frenchmen are equally fond is dancing. Excurſions to watering-places for pleaſure only and change of ſcene are confined to very few perſons of the very firſt claſſes of ſociety. The moſt renowned mineral waters of France are thoſe of Bagnères and Barrège in the Upper Pyrenees, Uſſat and Ax in the department of the Arriège, St. Amand in the department of the North, Bourbonne in the Upper Marne, Plombieres in the Voſges, Chaudes Aigues in the Cantal, Aix in the Bouches du Rhône, Sultz in the Lower Rhine, Sultzbach in the Upper Rhine, Spa in the department of the Ourte, and Aix la Chapelle in that of the Roër.

The French language is derived from the Latin. Its principal merit is the ſteady regularity of its conſtruction. Even French poetry admits few inverſions, and appears on that account extremely tame to the Engliſh, Germans, and Italians, whoſe poets, by the boldneſs of their inverſions, ſpeak as it were a language of their own. It was only in the beginning of the 17th century that the French commenced to write with elegance. The merit of the literary works produced in French in the reign of Louis XIV. is generally acknowledged, and though the preſent be more particularly the age of ſcience, France has yet ſome eminent men in the department of the belles lettres, ſuch as Delille, Le Brun, Bernardin de St. Pierre, Parny, Fontanes, Chénier, Colin d'Harleolle, Andrieux, Desfaucherets, St. Lambert, Monvel, Picard, Anquétil, Ségur, Suard; and it is not very long ſince ſhe has loſt her Voltaire, Rouſſeau, Buffon, d'Alembert, La Harpe, Marmontel, Boufflers, Favre d'Eglantine, Roucher, Condorcet, &c. The average number of new books publiſhed annually in France is from 1000 to 1200. But there is ſcarcely a town of 15 or 20,000 inhabitants which has not a literary ſociety, and the former royal academies at Paris have been replaced by a national inſtitute. (See PARIS.) The public libraries of France are alſo numerous and important. The national library at Paris alone contained, in the beginning of 1807, 300,000 printed books, 70,000 manuſcripts, 200,000 engravings, 40,000 copper medals, 30,000 gold medals, 30,000 ſilver medals, and many other curioſities.

France has a great many valuable remains of antiquity, which are detailed under the head of each department. There is in particular a moſt intereſting collection of monuments at Paris, called le Muſée des Antiques. See PARIS.

The conſequences of the revolution were very fatal to religion and public education; but the former is regaining its ſalutary influence on the principles and actions of the French, and the latter has recently been provided for by the eſtabliſhment of an imperial univerſity at Paris, which is excluſively charged with the public inſtruction, and controls every ſchool and ſeminary of education in the empire. It is compoſed of as many academies as there are tribunals or courts of appeal in France. There are ſchools attached to each academy, in the following order: 1. Univerſities, called les facultés; 2. Lyceums; 3. Colleges, or grammar ſchools; 4. Inſtitutions, or ſeminaries; 5. Boarding-ſchools, called penſionats; and, 6. The leſſer, or primary ſchools. The univerſities are compoſed of five faculties, *viz.* theology, juriſprudence, phyſic, mathematical and phyſical ſciences, and literature. The poet Fontanes, now comte de Fontanes, is grand maſter of the imperial French univerſity. There are alſo ſeveral eſtabliſhments for educating young men for ſome particular public ſervice, ſuch as the Ecole Polytechnique, which admits three hundred boys, that are generally inſtructed in mathematical and phyſical ſciences, chemiſtry, and drawing; and who, after a reſidence of three years, are examined and paſſed over, according to their particular inclination and talents, to the Ecoles des Ponts et Chauſſées, d'Artillerie de Terre, d'Artillerie de la Marine, des Génie Militaire, des Mines, des Ingénieurs de Vaiſſeau, &c. beſides which there are two military colleges at Fontainbleau and Saint Cyr.

In the year 1754, the marquis de Mirabeau, father of the celebrated count of that name, rated the whole population of France at 18 millions.

In 1772 the abbé d'Expilly eſtimated it at 22,140,357 individuals, and nearly at the ſame epoch the celebrated Buffon ſtated it at 21,672,777. In 1785 Mr. Neckar made it amount to 24,676,000.

In the year 1789 Mr. Bonvallet Deſbroſſes rated the population of France at 27,957,267, and in 1791 the committee of the National Aſſembly, from a more accurate calculation, ſtated it to be 26,363,074.

In 1798 Mr. Prony made the population of France, including Corſica and the conquered countries, amount to 31,123,218, *viz.*

26,048,254	on the territories of ancient France.
3,511,055	in the Comtat Venaiſſin, Savoye, Nice, Porentruy, Geneve, the Auſtrian Netherlands, &c.
1,563,909	in the countries ſituated between the Rhine and the Moſelle.

In 1799, Mr. Depere, in his Report to the Council of Five Hundred, ſtated it at 33,501,694.

The

The ſenatus conſultum of the 4th of Auguſt 1802 made the whole population of France amount to	33,111,962
To which muſt be added for Piémont and the iſland of Elba, which were incorporated with France on the 26th of Auguſt and 11th of September 1802,	1,864,351
which makes the whole population in 1802	34,976,313

The chevalier de Tinſeau, in the ſecond edition of his ſtatiſtical view of France, publiſhed at London in 1805, deviates very little from this ſtatement. He rates the whole population of France at 33,104,343, and gives for the ſix Piemonteſe departments 1,946,800

Making in all 35,051,143. To theſe muſt be added,

For the three departments of the Apennines, Genoa, and Montenotte, formed out of the Ligurian republic -	928,563
For the department of the Taro, formed out of the duchies of Parma and Plaiſance -	368,084
For the departments of the Arno, Mediterranean, and Ombrone, formed out of Tuſcany or the kingdom of Etruria -	956,068
And for the departments of Rome and Traſimene, formed out of the papal dominions -	800,000, which makes the whole
population of the French empire	38,103,858

But taking the population of France as it was in the beginning of 1802, when its territorial extent was 30,505 ſquare leagues, it gives 1086 inhabitants for the ſquare league.

The moſt populous towns of the French empire are,

1. Paris,	in	1803	had 672,000	inhabitants.
2. Rome,	in	1807	— 134,973	——
3. Marſeilles,	in	1807	— 96,413	——
4. Bourdeaux,	in	1807	— 90,992	——
5. Lyons,	in	1807	— 88,919	——
7. Turin,	in	1807	— 79,000	——
9. Genoa,	in	1807	— 75,000	——
6. Rouen,	in	1807	— 87,000	——
8. Nantes,	in	1807	— 77,162	——
10. Bruſſels,	in	1807	— 66,297	——
11. Antwerp,	in	1807	— 56,318	——

The annual number of births in France is as 1 to 25; and of theſe, every forty-ſeventh child in 1780 was illegitimate, whilſt the proportion now is that every eleventh child is illegitimate. The number of marriages is as 1 to [illegible]; the number of deaths as 1 to 30. The prefect of the department of the Doubs, on comparing the accounts of the children that died under ten years of age in 1800, and of thoſe that died under ten years of age in 1802, found that 939 more children had died in that ſingle department in 1800 than in 1802, and aſcribed the difference to the great progreſs which the introduction of the vaccine had made in the latter period.

The conſtitution of the French empire may be defined a military deſpotiſm engrafted upon a republican form of government, Napoleon Bonaparte having exchanged the conſular for the imperial dignity. The privy council, or ſtate council, in which the emperor preſides, and of which all the princes of the imperial family, the princes, great dignitaries of the empire, and the miniſters of ſtate are members, is compoſed of thirty privy counſellors, or counſellors of ſtate, and thirty-five auditors. The ſenate, of which the French princes and the great dignitaries are alſo members, is compoſed of eighty ſenators named by the emperor. The legiſlative body is compoſed of two hundred and fifty deputies of the different departments of the French empire.

There are ten miniſters and one ſecretary of ſtate, *viz.*

1. A miniſter for the department of the adminiſtration of juſtice, called great judge, (grand judge). 2. A miniſter for the foreign department. 3. For the home department. 4. For the financial adminiſtration of the empire. 5. A chancellor of the exchequer. 6. A war miniſter. 7. For the adminiſtration of the war department. 8. For the adminiſtration of naval and colonial affairs. 9. For the general police of the empire; and, 10. For the religious inſtitutions of the country. But theſe miniſters are accountable to the emperor only, and not to the nation.

The Roman Catholic religion has been declared that of the majority of the French people; but the ſtate provides equally for the miniſters of the reformed church, either of the Lutheran or Calviniſtic confeſſion, and ſuperintends even the ſynagogues of the Jews. The difference of religion is no bar to the advancement of any French citizen to the higheſt offices in the ſtate.

There is an inferior court of juſtice in every diſtrict, and a juſtice of the peace in every canton. Every department has a criminal court of juſtice. There are thirty-five courts of appeal, and two ſupreme tribunals, called the Haute Cour Impériale, and the Cour de Caſſation. The Code Napoléon regulates both the civil and criminal proceſs. But all theſe inſtitutions are of ſo recent a creation, that there are no data yet to pronounce on their merits.

According to Mr. Neckar's report of the 1ſt of May 1789, the public revenue of France at that time amounted only to 475,294,027 livres Tournois annually, whilſt the annual expenditure was 531,444,000 livres Tournois. There was of courſe an annual deficit of 56,149,973 livres. The preſent regular revenue of France is derived from a land-tax, a perſonal tax, a tax on moveables and ſumptuaries, on houſes and windows, on patentees, on the privilege of exerciſing any profeſſion, additional centimes or hundredths; from the produce of the national demeſnes and foreſts, cuſtoms, poſt office, lottery, ſalt mines, &c. all theſe taxes, in 1803, produced a ſum total of 569,500,000 francs, which,

together with contributions levied in foreign countries, called recette extérieure, and amounting to - - -	20,000,000
covered the expenditure of the ſame year amounting to	589,500,000 francs,

The principal heads of this expenditure were

1. Intereſt

1.	Intereſt of the national debt -	64,023,482 francs.
2.	Adminiſtration of juſtice - -	23,318,730
3.	Foreign department - -	7,000,000
4.	Home department - -	47,110,000
5.	Collection of the revenue and penſions - - -	56,047,788
6.	Public exchequer - -	6,000,000
7.	War department - -	243,000,000
8.	Naval department - -	126,000,000
9.	Sundries, and ſurplus in reſerve	17,000,000
		589,500,000

The national debt of France, which in 1789 exceeded three milliards, or three thouſand millions of francs, is reduced to leſs than one third, and as there are ſeveral annuities dropping off every year, it ſcarcely requires 60 millions annually for both the intereſt and the annuities. In the budget for the year following the above ſtatement of expenditure, both the intereſt of the conſolidated debt and the annuities are ſtated together at 58,730,000 francs. There is alſo a ſinking fund.

Beſides paying the general taxes and impoſts of the country, every department is obliged to provide for its adminiſtrative, judiciary, and ſchool expences.

The police of France, which even before the revolution was conſidered as excellent, is more vigilant than ever. It employs an incredible number of ſpies, and is powerfully aſſiſted by the national gendarmerie, a corps of 17,445 horſemen, divided into 28 legions, ſtationed by ſmall brigades all over the country, and deſtined to watch more particularly over the ſafety of the high roads.

There is no legal proviſion for the poor in France, but they are maintained in richly endowed charitable foundations, or ſupported by the liberality of a generous public. The hoſpital of the blind at Paris admits 420 blind individuals. The inſtitution for the deaf and dumb, which is become ſo celebrated by the talents of the late abbé de l'Epée, and its preſent director the abbé Sicard, admits only 60 pupils. There is a board of health at Charenton, a general hoſpital for gratuitous vaccination, and ſcarcely any town of importance is without infirmaries and charitable foundations. Begging is ſtrictly prohibited. Every beggar is taken to a dépôt de mendicité.

The army of France, that powerful engine with which ſuch aſtoniſhing deeds have been performed, and ſuch important changes operated on the continent of Europe, conſiſts of

90	Infantry regiments of the line, each at 3230 men each - - - - -	290,700
27	Regiments of light infantry, at 3230 men each	87,210
2	Regiments of carabiniers, at 706 men -	1,412
12	Regiments of cuiraſſiers, at 706 men -	8,472
30	Regiments of dragoons, at 946 men -	28,380
24	Regiments of chaſſeurs, at 946 men -	22,704
10	Regiments of huſſards, at 946 men - -	9,460
8	Regiments of artillery on foot, at 2582 men each	20,656
6	Regiments of hotillerie à cheval, at 524 men each	3,144
22	Battalions of the artillery train, at 477 men each	10,494
16	Companies of artillery labourers, at 78 each -	1,248
2	Battalions of pontoneers, at 610 men -	1,220
9	Companies of miners, at 100 men -	900
5	Battalions of ſapeurs, at 909 men - -	4,545
1	Battalion of gardes du génie - -	550
	Men	491,095

commanded by fifteen marſhals of the empire, 150 generals of diviſions, 300 generals of brigades, and 135 adjutants commandants. This army is recruited by voluntary enliſtings and by a rigorous conſcription, which comprizes all Frenchmen from the age of 20 to that of 25, without any diſtinction of rank, fortune, or buſineſs; but every ſoldier is entitled to be gradually promoted to the higheſt military appointments, provided he be found fit for the ſame. No military commiſſions whatever can be ſold. The military ſpirit of the French ſoldier is ſupported and animated by the decoration of a military order, which may be obtained alſo in a few caſes for civil merits, called the legion of honour, compoſed of 16 cohorts, poſſeſſed each of national demeſnes to the amount of an annual income of 200,000 francs. Each cohort conſiſts of ſeven great or ſuperior officers or dignitaries, 20 commanders, 30 officers, and 350 légionnaries. The great officers have an annual income of 5000 francs, the commanders 2000, the officers 1000, and the légionnaries 250. The knights of the legion of honour amount in all to 6512.

In the reign of Louis XIV. the French navy was ſtrong enough to equip a fleet of 63 ſhips of the line, 7 frigates, 36 veſſels armed en flute, and 14 cutters, under the orders of admiral de Tourville in the year 1690, and in 1704 the French fleet that fought the combined Engliſh and Dutch fleets at Veles Malaga conſiſted of 50 ſhips of the line, 8 frigates, and 9 fire ſhips. On the 1ſt of March 1791, the French had 73 ſhips of the line, 67 frigates, 19 cutters, 29 armed brigs, 7 gun boats, beſides ſeveral hoſpital ſhips, galliots, and others. But at preſent the French navy is reduced to a very low ſtate, and it is not probable that the intention of the French government to have at leaſt 100 ſhips of the line and 100 frigates afloat, will ſoon be realized. In the mean time the French have ſtill 7 vice-admirals, 16 rear-admirals, and about 200 poſt captains, on their navy liſt.

France holds at this moment the firſt rank among all the powers of the continent of Europe, and keeps them either in vaſſalage, or is in relations of amity with them all, except a ſmall portion of Spain, Great Britain, Portugal, and the iſland of Sicily.

The national character of the French has not been materially altered by their late political revolution. They are ſtill lively, polite, witty, amiable and brave; but vain glorious, inconſtant, volatile, and eaſily diſcouraged. They have been taxed of inſincerity in their offers of ſervices; but their wiſh to oblige ſtrangers whom they conſider as viſitors is really unfeigned. Mr. Pinckney, one of the lateſt travellers in France, obſerves that the French are unwearied in their acts of kindneſs. They offer their minor ſervices with ſincerity. They can never be ſufficiently praiſed for their indiſcriminate, their natural, their totally unintereſted and ſpontaneous benevolence.

FRANCE, *Iſle of*, a part of France, ſo called before the revolution, being bounded by the rivers Seine, Marne, Oiſe, Aiſne, and Ourque. Paris, ſituated in the centre, was its capital.

FRANCE, *Iſle of*. See MAURITIUS.

FRANCE, *School of Engravers in*. See FRENCH *ſchool of Engravers*.

FRANCESCA, PIETRO DELLA, commonly called *Franceſco Dal Borgo a San Sepolcro*, in *Biography*, was a painter of conſiderable merit and renown, for the early period of the art in which he lived.

He was born at Borgo in Umbria in 1372. In his youth he ſtudied the mathematics, and it was not till he was 15 years of age that he determined on being a painter, when he was patronized, or (as Vaſari terms it) adopted by Gindobaldo

baldo Fettro, duke of Urbino. He did not, however, ſo completely devote his time to painting, as to neglect his former ſtudies, but wrote ſeveral eſſays on geometry and perſpective, which were long preſerved in the duke's library at Urbino. He afterwards painted in Peſara, Ancona, and Ferrara; but few of his works remain at either of theſe places.

Having obtained much reputation, he was ſent for to Rome by pope Nicholas V. to paint two hiſtorical ſubjects in the chambers of the Vatican, in concurrence with Bramante di Milano, called Bramantino; but ſuch was the greater eſteem in which the talents of Raphael were juſtly held when he ſome years after flouriſhed, that Julius II. deſtroyed theſe two pictures to make room for his favourite artiſt to paint in their ſtead the miracle of Bolſena, and St. Peter in priſon.

Notwithſtanding this degradation of his labours, before the ſuperior powers of Raphael, he was very deſerving of eſteem, if the account which Vaſari gives of him be true, and we conſider the imperfect ſtate of the art at the time in which he lived. He exhibited much knowledge of anatomy, feeling of expreſſion, and of diſtribution of light and ſhade. The principal work of Franceſca was a night ſcene, in which he repreſented an angel carrying a croſs, and appearing in viſion to the emperor Conſtantine ſleeping in his tent with his chamberlain near him, and ſome of his ſoldiers. The light which iſſued from the croſs and the angel illuminated the ſcene, and was ſpread over it with the utmoſt diſcretion. Every thing appeared to have been ſtudied from nature, and was executed with great propriety and truth. He alſo painted a battle which was highly commended for the ſpirit and fire with which it was conducted; the ſtrength of the expreſſion, and the imitation of nature; particularly a group of horſemen, which Vaſari ſays, "conſidering the period, cannot be too highly commended."

Having exerciſed the various talents nature had beſtowed upon him, till he was 86 years old, he ſhared the common fate of mankind, and died in the year 1458.

FRANCESCAS, in *Geography*, a town of France, in the department of the Lot and Garonne, and chief place of a canton in the diſtrict of Nérac; ſix miles S.E. of Nérac. N. lat. 44° 3′. E. long. 0° 30′. The place contains 1314, and the canton 7624 inhabitants, on a territory of 145 kiliometres, in 21 communes.

FRANCESCHELLO, in *Biography*, the moſt exquiſite performer on the violoncello of his time, flouriſhed early in the laſt century. The admirable Benda, firſt violin to the king of Pruſſia, (Frederic,) and ſo juſtly celebrated for expreſſion on his inſtrument, in his life, written by himſelf, ſpeaks of the great advantage he received from frequently hearing and playing with Franceſchello. Geminiani uſed to relate of him, that in accompanying Nicolini, at Rome, in a cantata compoſed by Aleſſandro Scarlatti, for the violoncello, the author, who was at the harpſichord, would not believe that a mortal could play ſo divinely; but ſaid, that it was an angel who had aſſumed the figure of Franceſchello; ſo far did his performance ſurpaſs all that Scarlatti had conceived in compoſing the cantata, or imagined poſſible for man to expreſs.

FRANCESCHINI, Marc Antonio, an hiſtorical painter, born at Bologna in 1648. He was at firſt a diſciple of G. Battiſta Galli, and from him entered the ſchool of Carlo Cignani.

That maſter, who ſoon diſcovered the talents of his pupil, not only formed his ſtyle, but made him his relation by marrying him to his niece, and he ſoon became his principal aſſiſtant.

He was employed in embelliſhing many churches and convents in his native city, and in other parts of Italy; and particularly at Modena; he painted the grand hall of the duke's palace ſo much to the ſatisfaction of that prince, that he wiſhed to retain him at his court by an offer of a large penſion, and ſuch honours as were due to his merit. But Franceſchini preferred his freedom and eaſe to the greateſt acquiſitions of wealth, and with polite reſpect refuſed the offer. At Genoa he painted, in the great council chamber, a deſign, that at once manifeſted the fertility of his invention, and the grandeur of his ideas; for moſt of the memorable actions of the republic were there repreſented with a multitude of figures nobly deſigned, judiciouſly grouped and diſpoſed, and correctly drawn. And in the Palazzo Monti at Bologna is a ſmall gallery painted by him, of which the colouring is exceedingly lovely, though the figures appear to want roundneſs.

Franceſchini, though of the ſchool of Cignani, is original in the ſuavity of his colour, and the facility of his execution. He is freſh without being cold, and full without being crowded. As he was a machiniſt, and in Upper Italy what Cortona was in the Lower, ſymptoms of the Manneriſt appear in his works. He had the habit of painting his cartoons in chiaro-ſcuro, and, by fixing them to the ſpot where the freſco was to be executed, a judge of their effect.

He preſerved the powers of his mind and pencil unaltered at a very advanced age, and when he was even 78 years old, he deſigned and coloured his pictures with all that fire and ſpirit for which he had been diſtinguiſhed in his beſt time. He died in 1729, at the age of 81. Fuſeli's Pilkington.

Franceschini, Baldassare, called *Volterrano*, a painter of hiſtory, landſcape, and portrait, born at Volterra in 1621. He ſtudied under Matteo Sorella and Roſelli, but principally formed himſelf by his ſtudy of Corregio. He painted a great variety of works with conſiderable ſucceſs, but excelled principally in portrait. He died in 1689, aged 68.

FRANCESES, in *Geography*, a ſmall iſland near the coaſt of Brazil. S. lat. 20° 12′.

FRANCESINA, Signora, in *Biography*, a very pleaſing female Italian ſinger, and a beautiful woman, arrived in England in 1736, in order to ſing in the opera eſtabliſhed by the nobility and gentry againſt Handel; and the Daily Poſt, Nov. 18, of that year, informs us that "Sig'. Mirighi, Sig'. Clementi, and the Franceſina, (three ſingers lately come from Italy for the Royal Academy of Muſic,) had the honour to ſing before her majeſty, the duke, and princeſſes, at Kenſington, on Monday night laſt, and met with a moſt gracious reception; and her majeſty was pleaſed to approve their ſeveral performances: after which the Franceſina performed ſeveral dances to the entire ſatisfaction of the court." We believe ſhe never danced on the ſtage in England, though ſhe remained here as a ſinger to the end of her life. She however ſung for Handel at the end of his opera regency in Lincoln's-inn-fields, 1740, in the little drama of "Imeneo," or Hymen, and in 1741 in "Deidamia," the laſt opera which he compoſed, and in which ſhe had an air at the end of the firſt act, "Naſcondi l'uſignol," compoſed in a light airy ſtyle, ſuited to the active throat of the Franceſina. It was for the natural warble of this ſinger that Handel compoſed his Engliſh airs of execution, ſuch as "Sweet Bird," in Milton's Penſoroſa, "Myſelf I ſhall adore," and "The morning lark to mine attunes his throat," in Congreve's Semele, &c. Though the Franceſina came hither as ſecond woman, and had not a voice ſufficiently powerful for a firſt woman's part in a large theatre, having quitted the opera ſtage, ſhe attached herſelf to Handel, and was the principal ſinger in his oratorios during many years.

FRANCESIO, Araia, maeſtro di cappella to the court of Ruſſia, was born at Naples. His firſt eſſay in compoſition, after quitting the conſervatorio, was the opera of "Berenice," performed at the court of the grand duke of Tuſcany at Florence in 1730. This was followed, in 1731, by "Amore per regnante" for Rome. In 1735 he was called to Peterſburgh by the empreſs Anne, with a complete band of vocal and inſtrumental performers; where he compoſed the firſt Italian opera that was ever heard in that capital. During this reign concerts were eſtabliſhed at the imperial palace twice a week. In 1737 he ſet the opera of "Abiazure," and in 1738 "Semiramide," for the imperial theatre.

The empreſs Elizabeth, who began her reign in 1741, and had a paſſion for muſic, continued Araia in the office of maeſtro di cappella to the court. At her coronation, "La Clemenza di Tito" of Metaſtaſio, ſet by Haſſe, was performed, but with a prologue ſet by Araia, entitled "La Ruſſia afflitta e conſolata." Soon after this event Peterſburgh firſt heard an opera, "Cephalis and Procris," in the Slavonian language, which was likewiſe ſet in the Italian ſtyle by Araia, whoſe taſte was refined and melody graceful. He was honoured with the title of Aulic-counſellor, and received magnificent preſents from the court before he quitted Ruſſia, and in 1759 he returned to Italy poſſeſſed of conſiderable wealth, and ſettled at Bologna, where he enjoyed the fruits of his labours and good fortune in ſplendid eaſe and tranquillity.

FRANCESTOWN, in *Geography*, an interior poſt-town of America, in Hillſborough county, New Hampſhire, on the E. ſide of Contacook river, about 21 miles to the S.W. of Concord. It was incorporated in 1772, and in 1800 contained 1355 inhabitants.

FRANCFORT *on the Mayne*, a large, wealthy, imperial city of Germany, in the circle of the Upper Rhine, ſituated in a healthy, fertile, and beautiful country on the river Mayne, which divides it into two parts, diſtinguiſhed by the names of Francfort and Saxenhauſen; 20 miles N.E. of Mentz, and 350 W. by N. of Vienna. The whole city is divided into 14 wards, of which two are ſituated in Saxenhauſen. Its circumference is about a league and a half; its fortifications, conſiſting of a wall lined with towers, and ditches filled with water, ramparts, baſtions, &c. are regular and ſolid; but they ſerve chiefly for appearance, as the place is on all ſides eaſily acceſſible. Its garriſon commonly conſiſts of 13 companies of ſoldiers. The ſtreets are ſpacious, regularly paved, and well lighted. The houſes exhibit a ſplendid appearance, the ſhops are well ſtocked, and the inhabitants live in a coſtly ſtyle. No city in Europe contains larger and more magnificent buildings, elegant private houſes and commodious inns, all built of large and ſquare ſtones. The town-houſe, called "Römer," is a large magnificent building; and among its archives is ſeen a caſket of gold, containing the golden bull of the emperor Charles IV. in which are inſcribed, in Latin capital letters, the fundamental ſtatutes of the empire. In one of the churches belonging to the Roman catholics is a curious clock, conſiſting of three parts. In the loweſt, which has the appearance of a calendar, are ſeveral circles, the firſt of which ſhews the days and months; the ſecond the golden number, with the age and change of the moon; and the third the dominical letter. The fourth and fifth circles repreſent the ancient Roman calendar. On the ſixth are the names of the apoſtles and martyrs, the length of the days and nights, and the entrance of the ſun into the 12 ſigns of the zodiac. The ſeventh and eighth circles exhibit the hours and minutes of the ſun's riſing and ſetting. In the ninth circle, the diviſions of the 12 ſigns of the zodiac, the four ſeaſons, the 12 months, &c. are marked. The circle in the centre ſhews the moveable feaſts. The figures which ſtrike the hours repreſent two ſmiths with hammers in their hands. This curious piece of workmanſhip was put up in 1605, and repaired for the firſt time in 1704. In 1780 its inhabitants, including Jews and Catholics, were reckoned to be about 40,000. The Roman catholics have three churches, and the Lutherans ſix: the Calviniſts were formerly obliged to celebrate their worſhip at Bornheim, a village about ſix Engliſh miles from the city, belonging to the landgrave of Heſſe Caſſel. In the year 1790 they obtained permiſſion to erect public places of worſhip, and were allowed the free exerciſe of their religion. Their number is very conſiderable, and they are conſidered as the moſt induſtrious and wealthy of the inhabitants. The greateſt part of the Calviniſt families conſiſts of the deſcendants of French proteſtants, who left their country at the revocation of the edict of Nantz; they have two churches, to one of which belongs a German, and to the other a French preacher. There are ſeveral convents of female nobility, belonging to proteſtant families, the ladies of which are allowed to marry and to aſſociate with the moſt noble families in the city. There are alſo ſeveral Roman catholic male and female convents, the members of which do not keep public aſſemblies, and are enjoined celibacy by vow, conformably to the Roman catholic church. Here is alſo a ſeminary, named the "Engliſh Proteſtant Convent," eſtabliſhed for families of Engliſh extraction, whoſe predeceſſors fled to Hamburgh and to Holland during the perſecutions in the reign of queen Mary; the latter of whom, having been driven from Holland by the cruelty of the duke of Alva, found an aſylum for themſelves and their poſterity in this city. The Jews of Francfort are reckoned to be about 8000; they are reſtricted by law to a narrow ſtreet, and prohibited from living in any other part of the city. They have a public ſynagogue of conſiderable ſize. Francfort has not any univerſity; but it has many eſtabliſhed colleges, belonging to the learned of all ſciences, to which foreigners have free acceſs. Doctors of law, and all belonging to juriſprudence, medicine, ſurgery, natural hiſtory, natural philoſophy, mechanics, &c. meet regularly twice a week. Public lectures on theſe ſciences are delivered, and mechanical inventions are exhibited. Since the year 1789 an agricultural ſociety has been eſtabliſhed in this city. Society at Francfort is divided into the ancient and modern nobility, and "burgeois." The firſt conſiſts of ſome ancient noble families from various parts of Germany, who reſide here for ſeveral months in the year. Modern nobility comprehends thoſe who have obtained the rank of nobles, and are generally called "patricians," they reſide here continually; and ſo do the "burgeois," ſuch as bankers and great merchants who have made their fortunes by commerce, and who are very numerous.

Francfort is advantageouſly ſituated for trade; the articles which it exports conſiſt of wine, corn, hemp, timber, flax, iron, madder, ſeed of all ſorts, linen, lace, hides, leather, mineral waters, inland tobacco, hams, ſour krout, and many other raw materials, and minerals. Its trade is much aided by its two annual fairs, to which there is a great reſort of perſons from all parts of Europe. One fair begins on Eaſter Tueſday, the other in the middle of the month of September; and each continues three weeks. Six months before each fair begins, Francfort is ſupplied from all parts of the world with foreign ſtores, manufactures, &c. either by water or by land; and it may then be called a depôt of foreign productions. At the time of the fair, the wealthieſt merchants in the German empire reſort to this city, and by their purchaſe and ſales ſupply almoſt all other places on the continent of Europe. The third week of the fair is called the pay-week; and thoſe who then neglect their payments

are declared bankrupts, and obliged to fly the country till their affairs are ſettled, or if taken, are put under arreſt. The magiſtrates of Francfort are divided into three benches; the firſt is compoſed of 14 echevins, the ſecond of 14 counſellors, and the third chiefly of tradeſmen or artificers. All affairs of importance are decided by the two former, out of whom two burgomaſters are annually choſen; the third bench executes offices relating to the police. Francfort was aſſeſſed 500 florins for the Roman month, and is taxed to the imperial chamber 676 rix-dollars, 26 kreutzers. The government of this city is generally allowed to be one of the beſt and moſt moderate in Germany. During the reign of the emperor Joſeph II. many ſalutary laws were eſtabliſhed in this and other imperial cities. The old cuſtom of indulging extravagantly in the expence of funeral pomp and coſtly mourning, by which many families were ruined, has been altogether aboliſhed in Francfort. Another law was enacted, which prohibits the burying of dead bodies in any church or chapel whatever. All ſorts of beggars are alſo prohibited by law, and the wanderings of gypſies are alſo forbidden.

The origin of this ancient city has not been ſatisfactorily aſcertained. Some have aſcribed it to Marcomire, duke of Franconia, father to Pharamond: others to one of his predeceſſors, named Francus, who lived 100 years before him, and they ſay it was anciently called "Trajectum Francorum." It was alſo denominated "Helenopolis," from Helen, mother of Conſtantine the Great. In 1792 this city was taken by the French, but ſoon after reſigned to the Pruſſians. In 1796 it was ſurrendered to the French, and taxed to pay ſix millions of livres in ſpecie, and two millions in proviſions. On the defeat of Jourdan at Wurzburg, the French were obliged to evacuate it in the ſame year.

A council was held here in 794, againſt the hereſy of Felix, biſhop of Urgel, who taught that Chriſt was the ſon of God only by adoption; and another in 1006 to erect the city of Bamberg into a biſhopric. N. lat. 50° 7′ 40″. E. long. 8° 35′ 45″.

FRANCFORT *on the Oder*, a town of Germany, in the Middle Mark of Brandenburgh, containing about 16,000 inhabitants, with an univerſity, founded, as ſome ſay, in the year 1516, by the elector Joachim, or according to others by John Cicero, the father of this elector. The profeſſors are of the Calviniſtic perſuaſion. Beſides the univerſity it has a noble academy, a ſociety for promoting the arts and ſciences, two colleges, two fauxbourgs, and ſeveral churches. In the year 1806 this town fell into the hands of the French: 12 miles S.S.W. of Cuſtrin, and 48 E. of Berlin. N. lat. 52° 22′ 8″. E. long. 14° 45′.

FRANCHE-COMTE, anciently called Upper Burgundy, was, before the revolution, a province of France, bounded on the north by Lorraine, on the E. by Switzerland and Savoy, on the S. and W. by Burgundy and Champagne; lying between 46° 15′ and 47° 55′ N. lat., and between 5° 20′ and 6° 55′ E. long., being 39 leagues from N. to S. and 20 to 26 in breadth, and containing upwards of 700,000 inhabitants. Its form is oval, half of it is level, and the other half uneven and hilly. The ſoil conſiſts of red ferruginous loam, ſchiſtus, gravel, and lime-ſtone, and yields grain, wine, fruits, and excellent paſtures. It has mines of iron, copper, and lead. The moſt conſiderable rivers are the Saone, the Doubs, and the Oiguon. When this province was ſeparated from Burgundy it received its modern appellation; and by the treaty of Nimeguen, A.D. 1678, was annexed to France. It was divided into four large diſtricts, *viz.* Beſançon, Dole, Amont, and Aval, which now compoſe three departments, *viz.* Saone, Doubs, and Jura.

FRANCHIMONT, a town of France, in the department of the Ourthe, with a ſmall country to which the title of marquis was annexed; 13 miles S.E. of Liege.

FRANCHINUS, GAFFURIUS, in *Biography*, the firſt and the beſt writer on counterpoint in Italy, before the time of Zarlino. In the preface to an early edition of one of his works, the editor, Pantaleone Melegulo of Lodi, has given an account of his life and writings, whence we have extracted the following particulars. Franchinus Gaforius, or Gaforio, of Lodi, (Walther miſtakenly makes him a native of Lyons, in France, Lundenſis,) born 1451, was the ſon of Betino, a ſoldier in the ſervice of Gonzago, duke of Mantua, and Catherine Fixaraga, of the ſame place. He was firſt intended for prieſt's orders, but after ſtudying muſic for two years under friar John Goodenach, a carmelite, he manifeſted ſo much genius for that ſcience, that it was thought expedient to make it his profeſſion. After learning the rudiments of muſic at Lodi he went to Mantua, where he was patronized by the marquis Lodovico Gonzago; and where during two years he purſued his ſtudies with unwearied aſſiduity night and day, and acquired great reputation both in the ſpeculative and practical part of his profeſſion. From this city he went to Verona, where he read public lectures on muſic for two years more, and publiſhed ſeveral works; after which he removed to Genoa, whither he was invited by the doge Proſpero: there he entered into prieſt's orders. From Genoa he was invited to Milan by the duke and ducheſs Galeazzo, but they being ſoon after expelled that city, he returned to Naples, where Philip of Bologna, profeſſor royal, received him as his colleague; and he became ſo eminent in the theory of muſic, that he was thought ſuperior to John Tinctor, William Guarnieri, Bernard Yeart, and many celebrated and learned muſicians, with whom he now converſed and diſputed. He there compoſed and publiſhed his profound "Treatiſe on the Theory of Harmony," 1480; which was afterwards corrected, enlarged, and republiſhed at Milan, 1492; but the plague raging in Naples, and that kingdom being likewiſe much incommoded by a war with the Turks, he retreated to Otranto, in Apulia; whence, after a ſhort reſidence, he returned to Lodi, where he was protected and favoured by Pallavicino the biſhop, and opened a public ſchool, in which, during three years, he formed many excellent ſcholars. He was offered great encouragement at Bergamo if he would ſettle there; but the war being over, and the duke of Milan, his old patron, reſtored, he preferred the reſidence of that city to any other. It was here that he compoſed and poliſhed moſt of his works; that he was careſſed by the firſt perſons of his time for rank and learning; and that he read lectures by public authority to crowded audiences, for which he had a faculty granted him by the archbiſhop and chief magiſtrates of the city in 1483, which exalted him far above all his cotemporary brethren: and how much he improved the ſcience by his inſtructions, his lectures, and his writings, was teſtified by the approbation of the whole city; to which may be added the many diſciples he formed, and the almoſt infinite number of volumes he wrote, among which ſeveral will live as long as muſic and the Latin tongue are underſtood. He likewiſe firſt collected, reviſed, commented, and tranſlated into Latin the ancient Greek writers on muſic, Bacchius ſenior, Ariſtides, Quintilianus, Ptolemy's Harmonics, and Manuel Briennius. The order of the works which he publiſhed is as follows: "Theoricum Opus Harmonicæ Diſciplinæ," mentioned above, Neapolis, 1480, Milan, 1492. This was the firſt book on the ſubject of muſic that iſſued from the preſs after the invention of printing, if we except the "Definitiones Term. Muſicæ," of John Tinctor. "Practica

Muſicæ utriuſque Cantus," Milan, 1496, Breſcia, 1497, 1502; and Venice, 1512. "Angelicum ac Divinum Opus Muſicæ Materna Lingua Scrip." Milan, 1508. "De Harmonica Muſicor. Inſtrumentorum," Milan, 1518. This work, we are told by Pantaleone Melegulo, his countryman and biographer, was written when Gafforio was forty years of age, that is to ſay, in the year 1501; and though the ſubject is dark and difficult, it was abſolutely neceſſary for underſtanding the ancient authors. If, ſays Pantaleone, a life ſpent in labour for the advancement of ſcience, and in a ſeries of laudable actions, can entitle a human being to fame in this world, and felicity in the next, the claim of Gafforio to both ſeems indiſputable.

The doctrines of this venerable and excellent theoriſt, who died in 1520, are ſo frequently cited in the courſe of this work, that after the ample liſt juſt given, a table of contents, or extracts from them here, ſeem alike unneceſſary. We were diſappointed at not finding the name of Franchinus or Gaffurius, for he is called by both theſe titles in muſical books, either in Ducange or Fabricius. An authority ſo good and ſo ancient of the uſe of muſical terms in the Latin language would have been more ſatisfactory to the readers of Ducange, than that of many obſcure monks which he is obliged to cite: and Fabricius, who ſo frequently ſpeaks of muſical tracts and of their authors, might have furniſhed his work and his readers with a uſeful and intereſting article, in giving an account of Gaffurius and his writings, which, being chiefly compoſed in Latin, had a claim to his notice.

FRANCHISE, a ſpecies of incorporeal hereditament, having the privilege or exemption from ordinary juriſdiction. And the term is alſo uſed for an immunity from the ordinary tributes and taxes.

This is either real or perſonal; that is, either belonging immediately to the perſon, or accruing on account of this or that place, or office of *immunity*, which ſee.

Theſe franchiſes, being royal privileges, or branches of the king's prerogative, ſubſiſting in the hands of a ſubject, are derived from the crown by grant or charter, and in ſome caſes are held by preſcription and uſage. They may be veſted either in natural perſons, or bodies politic; in one man or in many; but the ſame identical franchiſe that has before been granted to one, cannot be beſtowed on another, for that would prejudice the former grant. The principal kinds of franchiſes are the following: to be a county palatine is a franchiſe veſted in a number of perſons. It is likewiſe a franchiſe for a number of perſons to be incorporated, and ſubſiſt as a body politic, with a power to maintain perpetual ſucceſſion, and do other corporate acts; and each individual member of ſuch corporation is alſo ſaid to have a franchiſe or freedom. Other franchiſes are to hold a court leet; to have a manor or lordſhip; or at leaſt, to have a lordſhip paramount; to have waifs, wrecks, eſtrays, treaſure-trove, royal fiſh, forfeitures, and deodands; to have a court of one's own, or liberty of holding pleas and trying cauſes; to have the cognizance of pleas, which is a ſtill greater liberty, being an excluſive right, ſo that no other court ſhall try cauſes ariſing within that juriſdiction; to have a bailiwick, or liberty exempt from the ſheriff of the county, wherein the grantee only and his officers are to execute all proceſs; to have a fair or market, with the right of taking toll, either there or at any other public places, as bridges, wharfs, and the like; which tolls muſt have a reaſonable cauſe of commencement, elſe the franchiſe is illegal and void; or, laſtly, to have a foreſt, chaſe, park, warren, or fiſhery, endowed with the privileges of royalty. See the ſeveral articles above recited.

FRANCHISE, *Allowance of.* See QUO *Warranto.*

FRANCHISE, *Diſturbance of.* See DISTURBANCE.

FRANCHISE is alſo uſed for an aſylum, or ſanctuary, where people are ſecure of their perſons, &c.

Churches and monaſteries in Spain are franchiſes for criminals; ſo were they anciently in England, till they were abuſed to ſuch a degree that there was a neceſſity for aboliſhing the cuſtom.

One of the moſt remarkable capitulars made by Charlemagne in his palace of Heriſtal, in 779, was that relating to the franchiſes of churches. The right of franchiſe was held ſo ſacred, that even the leſs religious kings obſerved it to a degree of ſcrupulouſneſs; but to ſuch exceſs in time was it carried, that Charlemagne reſolved to reduce it. Accordingly he forbade any proviſion being carried to criminals retired into churches for refuge.

FRANCHISE *of Quarters*, is a certain ſpace, or diſtrict, at Rome, wherein are the houſes of the ambaſſadors of the princes of Europe; and where ſuch as retire cannot be arreſted or ſeized by the ſkirri, or ſergeants, nor proſecuted at law.

The people of Rome look on this as an old uſurpation, and a ſcandalous privilege, which ambaſſadors, out of a jealouſy of their power, carried to a great length in the fifteenth century, by enlarging inſenſibly the dependencies of their palaces and houſes, within which the right of franchiſe was anciently confined. Several of the popes, Julius III. Pius XIV. Gregory XIII. and Sixtus V. publiſhed bulls and ordinances againſt this abuſe; which had reſcued ſo conſiderable a part of the city from their authority, and rendered it a retreat for the moſt abandoned perſons.

At length Innocent XI. expreſsly refuſed to receive any more ambaſſadors, but ſuch as would make a formal renunciation of the franchiſe of quarters.

FRANCHISE, *Royal*, is a place where the king's writ runs not; as at Cheſter and Durham; and anciently at Tyndal, and Hexamſhire in Northumberland. But Bracton ſays, that a franchiſe royal is where the king grants to one and his heirs an exemption of toll, &c.

FRANCHISING. See ENFRANCHISEMENT, and MANUMISSION.

FRANCIA, FRANCESCO, in *Biography*, an hiſtorical painter, who is known by that name, but whoſe real one was Raibolini. He was born at Bologna in 1450, and was bred to the profeſſion of a goldſmith, which he exerciſed for ſome time with very conſiderable celebrity, having the coinage of the city of Bologna under his care.

His deſire of reputation, and his acquaintance with Andrea Mantegna and other painters, led him to the ſtudy of painting, and in 1490 he produced a picture of the virgin ſeated, and ſurrounded by ſeveral figures; among whom is the portrait of M. Bart. Feliſini, for whom the picture was painted. This, and another picture of a ſimilar ſubject, painted for the chapel Bentivoglio a St. Jacopo, gained him great repute. He painted many pictures for churches, &c. in Bologna, Modena, Parma, and other cities; but they were in the early, Gothic, dry manner, which he greatly improved upon in his latter productions. On Pietro Perugino he formed his characters of heads, and his choice of tone and colour; on Gian. Bellino fullneſs of outline and breadth of drapery; and if the beſt evidence of his merit, the authority of Raphael, be of weight, in proceſs of time he excelled them both. In a letter dated 1508, edited by Malvaſia, Raphael declares, that the Madonnas of Francia were inferior in his opinion to none for beauty, devoutneſs, and form. His idea of Francia's talents exhibited itſelf ſtill ſtronger in his entruſting his picture of St. Cecilia, deſtined for the church of St. Gio da

Monte at Bologna, to his care, by letter ſoliciting him as a friend to ſee it put in its place, and if he found any defect in it that he would kindly correct it.

Vaſari ſays that Francia died with grief upon ſeeing by this picture that he was as nothing in the art compared with the ſuperior genius of Raphael. Malvaſia confutes Vaſari, and proves that he lived ſome years afterwards, and in an improved ſtyle produced his celebrated St. Sebaſtian, which Caracci deſcribes as the general model of proportion and form for the ſtudents at Bologna.

FRANCIA, in *Geography*, a town of Naples, in Calabria Ultra; 8 miles N.E. of Nicotera.

FRANCIABIGIO, MARCO ANTONIO, or *Francia Bigio*, in *Biography*, as Vaſari calls him, was an hiſtorical painter, born in 1483. He ſtudied for a ſhort time under Albertinelli, but is chiefly known as the competitor, and in ſome works the partner of Andrea del Sarto. Similar in principle, but inferior to him in power, he ſtrove to ſupply by diligence the defects of nature; with what ſucceſs, will appear on compariſon of his work in the cloiſter of the Nunziata at Florence, with thoſe of Andrea at the ſame place. On its being uncovered by the monks, the painter in a fit of ſhame or rage gave it ſome blows with a hammer, nor ever after could be induced to finiſh it. He appears to have ſucceeded better in two hiſtories which he inſerted among the freſcos of Andrea at the Scalzo, nor is he there much inferior. He likewiſe emulated him at Poggio a Cajano, where he repreſented the return of M. Tullius from exile, a work, which though it remained unfiniſhed, ſhews him to great advantage. Fuſeli's Pilkington.

FRANCIGENA, or FRENCHMAN, in our *Ancient Cuſtoms*, was a general appellation of all foreigners; *i. e.* all perſons who could not prove themſelves Engliſhmen.

FRANCIS I., in *Biography*, emperor of Germany, ſon of Leopold, duke of Lorrain, was born in the year 1708. In early life he ſerved with high reputation in the wars of Hungary and Bohemia. He married Maria Thereſa, daughter and heireſs of the emperor Charles VI., and having by the death of his father become duke of Lorrain, he ceded it to France, and obtained in its ſtead the duchy of Tuſcany as an indemnification. After the deceaſe of his father-in-law, Maria Thereſa aſſociated her huſband in the adminiſtration of her eſtates, and in 1745 he was elected to the empire. He obtained and merited the character of a humane prince, but was not great as an emperor. He was anxious to promote the good of his ſubjects, and was a patron of the arts and ſciences. He died at Inſpruck in 1765, leaving behind him a numerous family. Univer. Hiſt.

FRANCIS I., king of France, ſon of Charles Orleans, and Louiſa of Savoy, was preſumptive heir to the crown in the reign of Lewis XII. who married him to his eldeſt daughter. At the death of Lewis he ſucceeded to the throne, being then in his twentieth year. Formed with the mien of a hero, he excelled in the exerciſes of a martial age; eloquent in debate, and undaunted in action, courteous in his manners, and bounteous in his diſpoſition, his virtues and accompliſhments dazzled the unthinking crowd, who were blind to the miſeries which awaited his impetuous valour and inconſiderate ambition. He was impatient to diſtinguiſh himſelf, and reſolved to aſſert the claims of his houſe upon the duchy of Milan, and, paſſing the Alps with a powerful army, entered that country. To ſupply the funds for this expedition, Francis, by the advice of his chancellor, not only reſtored the taxes which his predeceſſor had aboliſhed, but expoſed the offices of the crown to ſale, and endeavoured to repleniſh his coffers by meaſures the moſt arbitrary and impolitic. A confederacy was formed againſt him by the emperor Maximilian, Ferdinand of Arragon, Leo X., Sforza, and the Swiſs: the number and reſources of his enemies ſeemed only to ſtimulate his ardour; the paſſes of the Alps which had been occupied by the Swiſs were eluded; new roads were cut by the active perſeverance of the French; the army, after having ſurmounted every obſtacle of nature and art, entered Italy, and ſurpriſed the general of the papal forces, who, ignorant of their approach, was negligently encamped with a thouſand cavalry on the banks of the Po. Francis, on receiving the intelligence of this ſucceſs, prepared to join his commander, and during his abſence devolved the regency of France on his mother Louiſa of Savoy, a princeſs, whoſe character in a great meaſure influenced the various events which diverſified the reign of her ſon. The king of France, on aſſuming the command of the army, entered the Milaneſe, and preſſed on towards the capital. He was oppoſed by the Switzers alone, who had encamped at Marignano, about a league from Milan. Hiſtory ſcarcely affords any example of a battle diſputed with greater obſtinacy than that of Marignano. It commenced about four in the afternoon, in the month of September, and laſted more than three hours after the night had cloſed in. Wearineſs and darkneſs ſeparated the combatants without abating their animoſity: the Swiſs renewed the charge in the morning with freſh vigour; but they were at length repulſed with cruel ſlaughter; ten thouſand periſhed on the field, and the reſt of their forces retired unbroken and undaunted, and ſtill truly formidable, though defeated. The loſs of the conquerors was computed at ſix thouſand men, and the intrepidity of the king expoſed him to the moſt imminent danger. When night ſuſpended the conflict he found himſelf intermingled with his enemies, and accompanied only by a few attendants. On the carriage of a cannon, completely armed, and anxious for the dawn, he ſnatched a few moments reſt; in every charge he was foremoſt; his horſe was wounded, and his body was covered with contuſions; but though his perſonal proweſs ſtood unrivalled, the victory of the day was chiefly to be aſcribed to the conſtable Charles of Bourbon, whoſe ſkill and martial genius were eminently diſplayed, and whoſe younger brother the duke de Chatelleraud fell gallantly fighting by his ſide. Francis diſplayed his chivalrous turn by receiving knighthood on the field of battle from the celebrated chevalier Bayard. The Milaneſe afterwards fell under his power, and pope Leo X. thought it adviſable to come to an agreement with him. The concordat made on the occaſion was ſo favourable to the pretenſions of the Roman ſee, that it excited conſiderable oppoſition in France, but the king's authority overcame all reſiſtance. The ambition of Francis led him to be a competitor for the imperial crown, left vacant by the death of Maximilian in 1519; but the ſuperior intereſt of Charles V. carried it againſt him, and the rivalſhip between theſe young monarchs began from that time to produce thoſe hoſtilities which ſo long diſturbed the peace of Europe. To gain Henry VIII. of England to his party, Francis procured that interview between them and their two courts, to which in another article we have lately referred, known by the name of "the field of the cloth of gold" (ſee FRANCE); in which, after a diſplay of unparalleled magnificence at a ruinous expence, no political purpoſe was effected; for ſerious buſineſs was not allowed to obtrude upon hours devoted to entertainment, and when the monarchs ſeparated, it might be, and probably was, a ſource of regret and great uneaſineſs to the French monarch, that a greater ſum had been laviſhed away in this fruitleſs pageantry than what Charles had diſtributed to acquire the imperial crown, and who by his bribes and promiſes to Wolſey eaſily deſtroyed all the impreſſion which the frankneſs of Francis had made upon the mind of Henry VIII. The king next over-ran the kingdom of Navarre, but ſoon loſt it again; in the mean time the

Milaneſe

Milaneſe revolted from the French, and expelled them from their country. At this period the conſtable Bourbon withdrew his ſupport from the French, and even turned his arms againſt them. This prince, having defeated Bonnivet, who was ſent upon an expedition into Italy, marched at the head of the imperialiſts into France, and laid ſiege to Marſeilles; but the place held out till it was relieved by the approach of Francis. Relying upon his own proweſs and the ſtrength of his armies, the king again croſſed the Alps, and inveſted the city of Pavia. Here he was attacked, February 24, 1527; but after the greateſt exertions of perſonal valour, Francis was obliged to ſurrender himſelf priſoner. By this defeat France was left without a ſovereign, without treaſures, and without an army. Ten thouſand of her braveſt ſoldiers had periſhed on the bloody field, and the moſt illuſtrious of her nobility had ſacrificed their lives to preſerve their honour. Among theſe the leaſt regretted was Bonnivet. His fatal counſels had precipitated the national calamity, and his haughty mind ſcorned to ſurvive the public diſaſter, but ruſhing into the thickeſt ranks of the enemy, he fell covered with wounds. The firſt intelligence of the rout at Pavia was tranſmitted by the king himſelf to his mother in a letter containing theſe memorable words: "Madam, all is loſt, except our honour." The royal captive was treated with every mark of reſpect, but when he was conveyed to the caſtle of Madrid, ſuch conditions were impoſed, or intended to be impoſed, on his releaſe, that he reſolved to die in captivity rather than accede to them. At length the emperor, finding his health evidently on the decline, paid him a viſit, and concluded a treaty for his liberation, which took place after he had been confined almoſt thirteen months. He was exchanged for his two ſons in a boat in the midſt of a ſtream which ſeparates France and Spain, and inſtantly upon touching his own ſhore, he mounted his horſe, and waving his hand over his head, cried out "I am yet a king." His firſt meaſure, on reſuming the reins of government, was to form a league with the pope, the Venetians, and the duke of Milan, againſt the emperor, and then, without any difficulty, he obtained from the holy pontiff Clement VII. an abſolution from his oath to obſerve the treaty of Madrid. And when Charles ſent embaſſadors to ſummon him to the performance of the conditions, Francis, for anſwer, introduced them to an aſſembly of the ſtates of Burgundy, who, as was preconcerted, explicitly declared that he had no right to alienate their country from his crown, and refuſed to have them transferred to the emperor's dominion. A war enſued, in the progreſs of which one of the principal actions on the part of the French was the ſiege of Naples, which was rendered unſucceſsful by the death of the general and a great part of his army by the plague. The defection of Doria completed the ruin of the French affairs in Italy. At length the peace of Cambray, in 1529, gave a temporary reſpite to the hoſtilities of the two rivals. By this the children of Francis were reſtored to him in conſideration of a ranſom of two millions of crowns, and the emperor for the preſent deſiſted from his claims on Burgundy, but without renouncing his right.

Some years of peace enſued, in which Francis diſplayed the character of a ſplendid and enlightened prince. The encouragement he gave to literature is a very ſtriking feature of his reign. Francis had a real love of learning, and invited many foreign ſcholars, among whom was Eraſmus, to take up their abode at Paris. He always kept men of ſcience and enlightened minds about his perſon, to whom he gave the heads of ſubjects on which he deſired information, and it was their buſineſs at leiſure times, and eſpecially at his meals, to read to him what they had drawn up. At the inſtigation, and with the aſſiſtance of his learned friends, he collected manuſcripts, augmented the royal library, founded a printing-office, and inſtituted the college for the learned languages. But he cauſed all public acts and law proceedings to be compoſed in the French language, inſtead of the barbarous Latin before in uſe. Francis was equally a friend to the fine arts; the palace of Fontainbleau, and ſeveral other edifices are monuments of this reign. To this prince the French court principally owes that free intermixture of the fair ſex which has ſince conſtituted its diſtinguiſhing luſtre and amenity. At the ſame time it muſt be acknowledged that the king himſelf, by a boundleſs propenſity to gallantry, ſet an example, as well of debauchery as of weakneſs; and his favourite miſtreſs, the counteſs d'Eſtampes, enjoyed her power in the ſtate as publicly as it was ever afterwards done during the French monarchy. In this reign Britanny was annexed to the crown of France; and the reformation excited in the mind of Francis as much attention as it did in the other princes of Europe. His ſiſter, the queen of Navarre, was addicted to the new opinions, which were likewiſe received by many of his ſubjects. The king, however, affected a great zeal for orthodoxy, and cauſed ſeveral heretics to be burned, with circumſtances of extraordinary cruelty, and probably with as little remorſe as the actors in this ſavage work would have experienced in any other buſineſs of their lives. A new war broke out between Francis and his rival Charles; this was in the year 1535, and it was continued with great animoſity for three years. Francis, to ſtrengthen his party, made an alliance with the Turks, a meaſure which excited the bitteреſt reproaches againſt him throughout Europe; nor was he himſelf inſenſible to the infamy which accompanied his confederacy with infidels againſt a Chriſtian king. Innumerable obſtacles ſeemed to oppoſe a definitive treaty; nevertheleſs each prince affected to liſten to the exhortations of the Roman pontiff, and Paul at laſt prevailed on them to ſuſpend their hoſtile efforts by a truce of ten years. In a very ſhort time after this pacification had been agreed upon, the rival monarchs held a conference with the greateſt demonſtrations of mutual friendſhip and confidence. In the year 1539, Charles, wiſhing to viſit the Low Countries, on account of a revolt of the people of Ghent, deſired permiſſion to paſs through France, and put ſo much truſt in the king's honour that he refuſed any other ſecurity for his ſafety than his mere word. He farther promiſed to confer the duchy of Milan upon the king's ſecond ſon, the duke of Orleans; Francis, pleaſed with this mark of confidence, received Charles at Paris with the greateſt magnificence, and gave him every facility in the proſecution of his deſigns. Charles was not equally liberal, and when he got to his own dominions, he meanly cavilled about his promiſe, and refuſed at laſt to perform it. This was the occaſion of a new war, in which Henry VIII. joined; peace was however concluded with the emperor in 1544, and with the king of England in 1546.

A diſeaſe, the fruit of his licentious amours, had long been preying upon the conſtitution of Francis, and his life was now embittered by domeſtic contention. The enmity and intrigues of his own miſtreſs, the ducheſs d'Eſtampes, and of Diana de Poitiers, miſtreſs to the Dauphin, divided the court into open and violent factions. The death of Henry VIII. inflicted a deep wound on the French monarch, who had long known and perſonally loved him: his own diſorder continually preyed upon him, he wandered from palace to palace languid and depreſſed, and, at length, at Rambouillet he cloſed, with much compoſure, in the fifty-third year of his age, a reign of thirty-two years, diſtinguiſhed, as well by its ſplendour, and its viciſſitudes of fortune, as by its length. He died in March 1547, at a time when he had

had begun to attend more ſeriouſly to his affairs, and by economy had brought his finances into a good condition. He left two ſons and four daughters. Francis was the founder of the houſe of Valois, that being his title when he aſſumed the crown: on his deceaſe the title of *great* was attached to his name, but by poſterity he has not been conſidered as meriting this high honour. He oppreſſed his ſubjects by exceſſive impoſts, and endangered his kingdom by ambitious projects. Nevertheleſs few ſovereigns of his country have been more diſtinguiſhed. The magnificence which accompanied him through life deſerted him not in his death: his funeral obſequies were performed with unuſual pomp; and the proclamation which announced his death, diſplayed his character as "a prince mild in peace, and victorious in war, the father and reſtorer of learning and the liberal arts." Moreri. Univer. Hiſt. Robertſon's Charles V.

FRANCIS II., king of France, eldeſt ſon of Henry II. by Catherine de Medicis, and grandſon to Francis I. was born in 1544. This prince married, at the age of fifteen, Mary Stuart, the beautiful and unfortunate queen of Scotland. He ſucceeded to the crown on the death of his father in 1559, and his reign was marked by violence and diſorder, which laid the foundation for thoſe civil contentions with which France was ſo long afflicted. As his youth rendered him incapable of holding the reins of government, and as he was alſo of a very delicate conſtitution, the duke of Guiſe, and his brother the cardinal of Lorraine, took upon them to govern in his name. Their party was joined by Catherine of Medicis, who had been declared regent. It was, however, her determination to break with the Guiſes, whenever ſhe ſhould find a fit opportunity, and to take the whole adminiſtration of government into her own hands. Meaſures were ſoon adopted againſt the Proteſtants, which excited them to ſelf-defence. An aſſociation was formed, and a plot was entered into to get poſſeſſion of the king's perſon, to baniſh or deſtroy the Guiſes, and to procure liberty of conſcience, but it was diſcovered and defeated with the death of its acting leader, La Renaudie, though the prince of Condé was ſuppoſed to be ſecretly at the head of the plot. A dreadful revenge was taken by the government, and all were executed who either took, or were ſuſpected of having taken, any part in it. By this unſucceſsful attempt the power of the Guiſes was eſtabliſhed, and the Proteſtant cauſe was ſtill more obnoxious than it had ever been. In order to appeaſe the diſorders which were becoming general, an aſſembly of notables was firſt called, which was followed by an aſſembly of the ſtates convoked at Orleans. The king of Navarre, and the prince of Condé, who attended, were put under an arreſt, and the latter was tried and condemned to loſe his head. The execution of the ſentence was delayed, and to this the prince of Condé was indebted for his life: for the king was ſuddenly attacked with a diſorder in his head which ſoon proved fatal; he expired in the eighteenth year of his age and the ſecond of his reign. His character, ſays the hiſtorian, preſents a blameleſs void: he was a king without vice, and almoſt without energy enough to produce one virtue. He had acted ſo entirely under the controul of others, that ſcarcely any thing had appeared of his natural diſpoſition: and amidſt the cabals of the various court intereſts, his corpſe was indecently neglected: Catherine, and the Guiſes were engaged in extending or in confirming their influence, and the funeral obſequies of the deceaſed monarch were only attended by thoſe who had been the governors of his education, and the biſhop of Senlis, who had long been blind. Moreri. Univer. Hiſt. Hiſt de France.

FRANCIS of Paulo, a Romiſh ſaint, born at Paulo, a town of Calabria, in the year 1416. He was devoted by his parents to a religious life from his birth, and entered accordingly into the Franciſcan convent at St. Marks. Having remained there about a year he engaged in various pilgrimages, and then adopted the hermit's life, in a ſolitary and ſecluded ſpot not far from his native town; after this he retired to a deſert part of the ſea-coaſt, where he found means to conſtruct for himſelf a cell among the rocks. The fame of his abſtinence and great ſanctity ſoon drew together a number of diſciples, who in the firſt inſtance built a chapel and a ſmall hermitage adjoining his cell; but their numbers rapidly increaſing, a monaſtery was built on the ſpot, which was the firſt belonging to the new order, of which the original denomination was that of the "Hermits of St. Francis." The ſubject of this article was the founder, and ſuperior general of the order, after his inſtitute had received the approbation of pope Sixtus IV. in the year 1473. The name of the order was afterwards changed to that of Minims, becauſe the humility of Francis was ſuch that he wiſhed himſelf and followers to be diſtinguiſhed by the appellation of "Fratres Minimi." The rules of the order were extremely rigorous, enjoining on the members a perpetual Lent, and great ſeverity of perſonal diſcipline. No one was ſo ſtrict in conforming to the precepts of the order as the inſtitutor himſelf: he allowed himſelf nothing but bread and water: he ſlept on the bare floor without pillow or covering, and he wore as his uſual dreſs a rough hair-cloth next his ſkin. Hence he acquired, in thoſe days of ignorance and barbariſm, the higheſt character for piety and virtue; and ſo great was the opinion entertained of his ſanctity, and of the prevalence of his interceſſions with heaven, that when Lewis XI. of France was attacked by a dangerous diſtemper, he ſent for Francis out of Calabria, hoping to obtain a cure by virtue of his prayers. The ſaint at firſt refuſed to comply with the royal demand, and was at laſt induced to ſet out on the journey by an expreſs order from the pope. He was received by Lewis with the greateſt honour, and had apartments aſſigned to him in the palace, and after the death of the king, his ſucceſſor Charles VIII. built a convent for Francis and his monks in a park belonging to that palace. Here he died, in 1507, at the advanced age of ninety-one years. He was highly applauded for his ſanctity, but was a total ſtranger to literature: the auſterities which he practiſed upon himſelf ſtood in ſtead of every other accompliſhment. In 1519 he was canonized by pope Leo X. Moreri.

FRANCIS XAVIER, a Romiſh ſaint, ſtyled "the Apoſtle of the Indians," was ſon of John Jaſſe, a gentleman of Navarre, and born at the chateau of Xavier, at the foot of the Pyrenees, in the year 1506. Having attained a competent ſtock of claſſical learning, he was ſent to Paris, where he went through a courſe of philoſophy, and took his degrees. Some time after this he undertook to teach philoſophy in the college of Beauvais, until he became acquainted with the famous Ignatius Loyola, with whom he ſolemnly embarked in a new undertaking, for promoting the intereſts of the catholic faith, particularly by the converſion of infidels. From this time he renounced all proſpect of any eſtabliſhment in the world, and applied himſelf diligently to the ſtudy of theology. In the year 1537, he quitted Paris, and went to Venice, where Loyola, who had taken a journey into Spain to ſettle ſome affairs, met him and the reſt of his companions. He next went to Rome, where he obtained leave of the pope for himſelf and others to embark on a miſſion to the holy land, and alſo to be admitted to prieſt's orders. They were, however, prevented from undertaking the voyage by the reſtrictions which the grand ſeignior had laid on the admiſſion of pilgrims and miſſionaries into Paleſtine. They, therefore,

turned

turned their thoughts to increaſing their numbers from among the members of the different Italian univerſities, in preaching and inſtructing young perſons, and in laying the foundation of the famous ſociety of Jeſus. Almoſt as ſoon as the pope had given his ſanction to the eſtabliſhment of this new order, John III. king of Portugal applied to the holy ſee of Rome for miſſionaries to be ſent to propagate the catholic faith in the Eaſt Indies. Francis Xavier was one of the perſons ſelected for this arduous enterprize; he embarked at Liſbon for the Indies in 1541, and in the following year arrived at the Portugueſe ſettlement at Goa, where he laboured inceſſantly in ſpreading the knowledge of the catholic faith in that city, the ſouthern continent of India, Malacca, the Molucca iſlands, and Japan. Many became converts to chriſtianity, and at Japan, Francis Xavier, with wonderful rapidity, laid the foundation of the catholic church, which flouriſhed for many years in that vaſt empire. From Japan he went to China, but was taken ſick on his voyage, and died in ſight of the empire in 1552, in the forty-ſixth year of his age. As an author he is known by five books of "Epiſtles," publiſhed at Paris in 1631; "a catechiſm," and ſome other ſmall pieces. He was beatified by pope Paul V. in 1613, and canonized by his ſucceſſor pope Gregory XV. in 1662.

Francis de Borgia, a Romiſh ſaint, born about the year 1511, was grandſon of pope Alexander VI. and hereditary duke of Candia. He was by birth a Spaniard, obtained the viceroyſhip of Catalonia, and from his connections he might have obtained the higheſt honours of the ſtate; but he grew diſguſted with the world, and determined to embrace the eccleſiaſtical life. He became a member of the ſociety of Jeſus in 1548, and, in 1565, he was raiſed to the poſt of general of that order. He frequently declined valuable eccleſiaſtical dignities, as well as the high honour of the cardinalate, and dedicated his whole time and labour to the advancement of the intereſts of the ſociety. By the expreſs wiſh of pope Pius VI. he accompanied his nephew cardinal Alexandrinus, whom he ſent legate into Spain, Portugal, and France. He died at Rome in 1572, in the 62d year of his age, having been canonized the year before. He was author of ſeveral theological and devotional pieces written in the Spaniſh language, which were afterwards tranſlated into Latin, and publiſhed in folio at Bruſſels in 1675. Moreri.

Francis de Sales, a ſaint and founder of the religious order of the "Viſitation," was born at Sales, near Geneva, in the year 1567, and was educated partly at Annecy and partly at the univerſity of Paris. He was intended for the profeſſion of the law, but this not being congenial to his mind he embraced the eccleſiaſtical life. He ſoon became diſtinguiſhed as a popular preacher, and poſſeſſed a moſt ardent zeal in the converſion of heretics, and on that account was ſent by his biſhop on miſſions into the valleys of his dioceſe, to endeavour to bring back the diſciples of Zuingle and Calvin into the true church. He was afterwards appointed coadjutor to the biſhop of Geneva, and was conſecrated under the title of biſhop of Nicopolis. Having occaſion to take a journey to Paris, the moſt handſome offers were made him by Henry IV. but he declined the appointment, as he did alſo the honour of a cardinalate. On the death of the biſhop of Geneva, he was called to the full exerciſe of the epiſcopal functions in that dioceſe, when he applied himſelf with great diligence to the reformation of abuſes among the clergy, and united in his own perſon, to the character of a vigilant eccleſiaſtical ſuperintendant, that of a good paſtor, and benevolent friend of the people committed to his care. In every caſe of diſtreſs he was ready to afford his aſſiſtance, and in his own life he exhibited a large ſhare of piety, purity, candour, and unaffected ſimplicity and urbanity. Still the moſt prominent traits in his character were the zeal and activity which he exhibited in winning over the proteſtants to the catholic faith. He is ſaid to have been the means of reconciling above 70,000 heretics to the church of Rome, during the ten years before his ſucceſſion to the epiſcopate of Geneva; and after that event he perſevered in the ſame courſe with equal diligence and proportionate ſucceſs. In the year 1610, he eſtabliſhed, in conjunction with madame de Chantal, the order of the "Viſitation," for female devotees, of which the firſt inſtitution was fixed at Annecy. In 1622, the biſhop received an order from the duke of Savoy to proceed to Avignon, to be preſent at an interview between that prince and Lewis XIII. of France. From hence he went to Lyons, where he died in the fifty-fifth year of his age. He was canonized by pope Alexander VII. in the year 1665. As an author he is known by many devotional pieces highly eſteemed by the catholics. Theſe have been collected and publiſhed in two volumes folio. Moreri.

Francis, or Franciscus de Victoria, a celebrated Spaniſh divine in the 16th century, purſued his ſtudies at Paris, where he took his degrees. He entered into the order of the Dominican preaching friars, was appointed profeſſor of theology, and delivered lectures at Salamanca and other celebrated Spaniſh univerſities. His works as an author have been highly prized in the catholic world; but the moſt important of them is a collection of theological and moral lectures, entitled Theologicæ Prælectiones XIII. in two volumes, which have obtained the critical notice of Dupin. He died at Salamanca in the year 1549. Moreri.

Francis de Jesus-Maria, a learned Spaniſh carmelite monk of the reformed order of St. Thereſa, who flouriſhed in the 17th century, was a native of Burgos in Old Caſtile. He obtained the high office of definitor-general; was author of "Curſus Theologiæ moralis Salmanticenſis;" and of "Commentaries on the Apocalypſe" publiſhed at Lyons in 1648, in two volumes folio. He died in 1677.

Francis, *St.* in *Geography*, a lake, or extenſion of the river St. Lawrence, between Kingſton and Montreal, through which paſſes the line dividing Upper from Lower Canada.—Alſo, a river in the province of Lower Canada, which riſes from various ſources near the northern boundary of the United States, and runs northward into the river St. Lawrence, at the W. end of lake St. Peter. If it were all the way navigable, it would afford an important communication from the northern parts of Vermont, to the markets of Montreal and Quebec. Its banks are fertile, and accommodate ſettlers, who reſort thither from New England.—Alſo, a ſmall river in Louiſiana, which purſues a S. E. courſe into the Miſſiſſippi, 108 miles above Arkanſas river, and 70 miles above Margot river on the E. ſide of the Miſſiſſippi. It is the general rendezvous for the hunters from New Orleans, who winter there, and collect ſalt meat, ſuet, and bear's oil, for the ſupply of that city.—Alſo, the name of a ſmall river in the W. territory, which runs a S. W. by W. courſe into the Miſſiſſippi, between Cold and Rum rivers, 60 miles above S. Anthony's Falls. The country above it is hilly, and the ſoil tolerably good. To the N. E. are the ſmall lakes called the Thouſand Lakes. Here the Miſſiſſippi is not above 90 yards wide.

FRANCISCANS, in *Eccleſiaſtical Hiſtory*, are religious of the order of St. Francis, founded by him in the year 1209. Francis was the ſon of a merchant of Aſſiſi, in the province of Umbria, who, having led a diſſolute life, was reclaimed by a fit of ſickneſs, and afterwards fell into an extravagant

extravagant kind of devotion, that looked leſs like religion than alienation of mind. Soon after this, *viz.* in the year 1208, hearing the paſſage repeated, Matt. x. 9, 10. in which Chriſt addreſſes his apoſtles, "Provide neither gold nor ſilver, &c." he was led to conſider a voluntary and abſolute poverty as the eſſence of the goſpel, and to preſcribe this poverty as a ſacred rule both to himſelf and to the few that followed him. This new ſociety, which appeared to Innocent III. extremely adapted to the preſent ſtate of the church, and proper to reſtore its declining credit, was ſolemnly approved and confirmed by Honorius III. in 1223, and had made a conſiderable progreſs before the death of its founder in 1226. Francis, through an exceſſive humility, would not ſuffer the monks of his order to be called *fratres*, *i. e.* brethren, or friars, but *fraterculi*, *i. e.* little brethren, or friars-minor, by which denomination they ſtill continue to be diſtinguiſhed. They are alſo called *grey friars*, on account of the colour of their cloathing, and cordeliers, &c. The Franciſcans and Dominicans were zealous and active friends to the papal hierarchy, and, in return, were diſtinguiſhed by peculiar privileges and honourable employments. The Franciſcans, in particular, were inveſted with the treaſure of ample and extenſive indulgences, the diſtribution of which was committed to them by the popes, as a means of ſubſiſtence, and a rich indemnification for their voluntary poverty. In conſequence of this grant, the rule of the founder, which abſolutely prohibited both perſonal and collective property, ſo that neither the individual nor the community were permitted to poſſeſs either fund, revenue, or any worldly goods, was conſidered as too ſtrict and ſevere, and diſpenſed with ſoon after his death. In 1231, Gregory IX. publiſhed an interpretation of this rule, mitigating its rigour; which was farther confirmed by Innocent IV. in 1245, and by Alexander IV. in 1247. Theſe milder alterations were zealouſly oppoſed by a branch of the Franciſcans, called the *ſpiritual*; and their complaints were regarded by Nicholas III. who, in 1279, publiſhed a famous conſtitution, confirming the rule of St. Francis, and containing an elaborate explication of the maxims it recommended, and the duties it preſcribed. In 1287, Matthew of Aqua Sparta, being elected general of the order, diſcouraged the ancient diſcipline of the Franciſcans, and indulged his monks in abandoning even the appearance of poverty; and this conduct inflamed the indignation of the ſpiritual or auſterer Franciſcans; ſo that from the year 1290, ſeditions and ſchiſms aroſe in an order that had been ſo famous for its pretended diſintereſtedneſs and humility. Such was the enthuſiaſtic frenzy of the Franciſcans, that they impiouſly maintained, that the founder of their order was a ſecond Chriſt, in all reſpects ſimilar to the firſt; and that their inſtitution and diſcipline were the true goſpel of Jeſus. Accordingly, Albizi, a Franciſcan of Piſa, publiſhed a book in 1383, with the applauſe of his order, entitled, "The Book of the Conformities of St. Francis with Jeſus Chriſt." In the beginning of this century the whole Franciſcan order was divided into two parties; the one embracing the ſevere diſcipline and abſolute poverty of St. Francis, were called *ſpirituals*; and the other, who inſiſted on mitigating the auſtere injunctions of their founder, were denominated "brethren of the community." Theſe wore long, looſe, and good habits, with large hoods; the former were clad in a ſtraight, coarſe, and ſhort dreſs, pretending, that this dreſs was enjoined by St. Francis, and that no power on earth had a right to alter it. Neither the moderation of Clement V. nor the violence of John XXII. could appeaſe the tumult occaſioned by theſe two parties; however, their rage ſubſided from the year 1329. In 1368 theſe two parties were formed into two large bodies, comprehending the whole Franciſcan order, which ſubſiſt to this day; *viz.* the "conventual brethren," and the "brethren of the obſervance, or obſervation," from whom ſprung the Capuchins and Recollects. Moſh. Eccl. Hiſt. vol. iii. See alſo *Nuns of St.* CLARE, and FRIARS. The general opinion is, that the Franciſcans came into England in the year 1224, and had their firſt houſe at Canterbury, and their ſecond at London; but there is no certain account of their being here till king Henry VII. built two or three houſes for them. At the diſſolution of the monaſteries, the conventual Franciſcans had about fifty-five houſes, which were under ſeven cuſtodies, or wardenſhips; *viz.* thoſe of London, York, Cambridge, Briſtol, Oxford, Newcaſtle, and Worceſter.

FRANCISCO DE TRADO, in *Geography*, a town of Brazil; 80 miles S. E. of Pauxis.

FRANCISCO, *St.* a river of Brazil, which diſembogues itſelf into the bay of Vaſabarris, ſouthward of Fernambuco, occaſioning ſuch eddies to the diſtance of three or four leagues from the land, that few veſſels which approach near the ſhore in this bay eſcape ſtranding. About 30 leagues inland this river loſes itſelf, running under ground for ſeveral miles, and again makes its appearance. On the banks of this river there are ſeveral villages, and large plantations, from which the inhabitants ſend annually great quantities of ſugar, tobacco, and mandioc to Fernambuco, exchanging theſe commodities for cloathing and implements of huſbandry. The bar of the river has not above eight feet of water upon it, ſo that they are obliged to uſe ſmall ſchooners for the convenience of exporting their goods.

FRANCIUS, PETER, in *Biography*, a celebrated Greek and Latin poet, was born at Amſterdam in 1645. Here and at Leyden he purſued his ſtudies under Hadrian Junius, and Gronovius, with whom he entered into a moſt intimate friendſhip. In 1669, he made a tour to England, from whence he proceeded to France, where he obtained the degree of doctor of laws. He formed an acquaintance with many of the moſt learned men of the age in which he lived; was treated with high reſpect by the grand duke at Florence, and at Rome he was viſited by the principal people of the city. In 1674, the magiſtrates of Amſterdam appointed him profeſſor of hiſtory and rhetoric, and, in 1692, he was invited to be profeſſor of Greek, which he declined, and continued to diſcharge the duties of his office at Amſterdam till his death in 1704. He was deeply ſkilled in Latin poetry and oratory, though ſome excellent judges have thought more highly of his Greek verſes than of thoſe which he compoſed in Latin. His oration, "De Præſtantia Linguæ Græcæ," poſſeſſes great merit. Many of his poems were written on William III. king of England; Frederic-William, elector of Brandenburg, and his ſon, the firſt king of Pruſſia; and after his death a number of gold coins and other valuable preſents, which he had received from theſe and other princes and great men were found among his property. His works are numerous, and conſiſt chiefly of poems, orations, and diſſertations. Gen. Biog.

FRANCK DE FRANCKENAU, GEORGE, was born at Naumburg, in Upper Saxony, on the third of May 1643. His father, although living as a ſimple peaſant, was of a noble family. After going through his ſchool-education, George went to Jena at the age of 18, and was crowned a poet by count palatine Richter, in conſequence of his extraordinary talent for writing verſes in the German, Latin, Greek, and Hebrew languages. But he exhibited ſtill greater talents during his courſe of medical ſtudies; and the canons of Naumburg, who recognized his merits, afforded

him liberal means of ſubſiſtence while he applied himſelf to this ſcience. He made ſuch good uſe of their money and his time, that he was deemed eligible to give lectures in botany, chemiſtry, and anatomy, before he obtained the degree of doctor, which, after having fulfilled theſe duties, he received at Straſburg in 1666. He continued his progreſs in the cultivation of his profeſſion with great ſucceſs; and the progreſſive increaſe of his reputation was at once the reſult and the recompence. In 1672, the elector palatine appointed him to the vacant profeſſorſhip of medicine at Heidelberg, and a few years afterwards nominated him his own phyſician. But the troubles occaſioned by the war compelled Franck to leave Heidelberg in 1688, and he retired to Francfort on the Main. John George III., elector of Saxony, then received him into his ſervice, and appointed him profeſſor of medicine at Wittemberg; an office which he filled with ſo much eclat, that the principal profeſſorſhip, and the title of dean of the faculty at Leipſic, were ſoon offered to him. This, however, he refuſed, by the inſtigation of his friends, who ſought to retain him at Wittemberg. The two ſucceeding electors likewiſe loaded this phyſician with ſo many favours, that it was ſuppoſed he could never dream of quitting Heidelberg. Nevertheleſs he was induced, by the offers of Chriſtian V. king of Denmark, to remove to Copenhagen, where he was received moſt graciouſly by the royal family, and was honoured with the title of Aulic counſellor, which was continued to him by Frederick IV. the ſucceſſor of Chriſtian. Death, however, terminated his brilliant career on the 16th of June 1704, in the 60th year of his age.

Franck was a member of ſeveral learned ſocieties, and was ennobled by the emperor Leopold in 1692, and in 1693 was created count palatine, by the title of "De Franckenau." He wrote many works, but it will be ſufficient to enumerate the titles of thoſe which have obtained the moſt extenſive circulation. 1. "Inſtitutionum Medicarum Synopſis," Heidelberg, 1672. 2. "Lexicon Vegetabilium uſualium," Argentorati, 1672. This was republiſhed ſeveral times. In the edition of Leipſic 1698, the title of "Flora Francica" was given to it. 3. "Bona nova Anatomica," Heidelberg, 1680. 4. "Parva Bibliotheca Zootomica," ibid. 1680. 5. "De calumniis in Medicos et Medicinam," ibid. 1686. 6. "De Medicis Philologis," Wittebergæ, 1691. 7. "De palingeneſia, ſive reſuſcitatione artificiali plantarum, hominum, et animalium, è ſuis cineribus, liber ſingularis," Halæ, 1717, edited by Nehring. 8. "Satyræ Medicæ XX." Leipſic, 1722. Theſe pieces, which had begun to appear in 1673, were publiſhed by his ſon, George Frederick Franck, who was alſo a teacher of medicine at Wittemberg, and wrote ſeveral works on botany and phyſic. Eloy. Dict. Hiſt.

FRANCKE, Augustus Herman, a learned German Lutheran divine, was born at Lubeck in 1663, where he received the early parts of his education, and, in 1679, he was ſent to the univerſity of Erfurt, and from thence to Kiel, in both which places he diſtinguiſhed himſelf by his diligence and improvement. In 1682, he ſpent ſome time at Hamburgh, to perfect himſelf in the Hebrew language under a learned Jew in that city, and then went to Gotha, whence, in 1684, he proceeded to Leipſic, where, in the following year, he was admitted to the degree of M. A. Here, after he had been at Wittemberg and Lunenburg for improvement, he delivered lectures on the ſcriptures, in which he combined critical diſcuſſion with practical and uſeful reflections. His popularity was ſo great as a lecturer, that he is ſaid to have had frequently 300 ſtudents, but from ſome cauſes not diſtinctly aſcertained, he was obliged to relinquiſh his lectures, and to withdraw from the univerſity. No imputation was ever made to affect his moral character, and, in 1690, he was called upon to undertake the office of miniſter of one of the churches of Erfurt, but through jealouſy of his ſuperior talents he was in a few months deprived of that ſituation, and ordered to quit the place. Upon this event, which was marked with injuſtice, the court of Gotha, ſatisfied of his innocence and of his merit, immediately offered him a choice of preferments, but having received, at the ſame time, an invitation from the elector of Brandenburg, to become profeſſor of the oriental and Greek languages in the univerſity at Halle, he gave the preference to this; which, however, he ſoon reſigned for the profeſſorſhip of divinity. He now employed his talents in inſtructing the poor, and engaged, at his own expence, a ſtudent in the univerſity to aſſiſt in the ſame plan. Soon after, he extended his project, and formed an eſtabliſhment, to be ſupported by voluntary contributions, in which orphans, and other neceſſitous children, ſhould be inſtructed and ſupported, until they were qualified to be ſent out into the world. This was the commencement of the hoſpital, or houſe of orphans at Halle; an inſtitution that has been of eſſential ſervice to the intereſts of humanity and good morals in Germany, and has rendered the memory of Francke highly reſpected. He lived to ſee this inſtitution flouriſh in ſuch a manner as abundantly to repay all his labours: proviſion was made in it, and in others connected with it, for more than two thouſand children. Having provided for their neceſſaries, he began to contrive plans for the enlargement of their ſtudies: he eſtabliſhed a printing office, and furniſhed it with the means of printing books in all languages, even thoſe that are leaſt generally known; a muſeum of natural curioſities, and a numerous library. The zeal and activity manifeſted by Mr. Francke in his benevolent ſchemes injured his health ſo much, that he was obliged to ſeek relief from foreign travel: this ſeemed, for a time, to ſtop the progreſs of diſeaſe; nevertheleſs his infirmities were evidently increaſing, and though they did not, for the preſent, incapacitate him entirely for public duty, yet they prevented him from any conſiderable exertions, and, in 1727, he died in the 65th year of his age, regretted by all ranks in Germany, for the noble ſervices which he had rendered his country and the world. He was author of many theological works, ſeveral of which were intended to explain and illuſtrate the books of the Old and New Teſtament. Moreri.

FRANCKEN, or Francks Franciscus, commonly called *Old Franck*, a native of Flanders, who practiſed hiſtorical painting with very conſiderable ſucceſs in a ſmall ſtyle of proportion. His birth is fixed in 1544, but when he died is uncertain, but ſuppoſed to be in 1616, at the age of 72.

He poſſeſſed the power of invention, and compoſed with great eaſe the ſubjects he choſe for repreſentation, which were generally from the Old or New Teſtament. He ſeems to have imagined it to be the quinteſſence of art, to introduce as many figures as poſſible into his pictures; and beſides this he had the fault of the time he lived in, *viz.* introducing ſeveral points of time, or parts of the hiſtory of his heroes, into one picture. Excepting theſe defects, his works are worthy of admiration for the ingenuity of the execution. At Wilton is a work of his repreſenting Belſhazzar's feaſt, which is beautifully wrought; but the compoſition is exceedingly confuſed from the number of the figures and the management of the lights. It could not well be more ſo if the painter's head had been filled with the vapours of Belſhazzar's wine.

Francken, or Franckes Franciscus, commonly called

Young

Young Franck, ſon of the preceding, was born in 1580, and followed his father's profeſſion as hiſtorical painter, in the ſame ſtyle and manner, but with conſiderable improvement in colour and expreſſion; and his deſigns were conducted with more elegance and greater clearneſs, though ſtill with the fault of having often too many hiſtorical incidents in one picture, repreſenting by that means a ſeries of incidents, inſtead of one principal action or event.

After ſtudying ſome time with his father, he travelled to Venice to improve his taſte in colouring. There he copied, and attentively ſtudied, the works of the great artiſts that had been, and were then employed in adorning that city. At his return to Flanders he was greatly admired and encouraged, though he does not appear to have carried back with him much of the taſte of the Venetian, or any of the Italian ſchools; but continued the practice of his father, painting ſmall hiſtories with a great number of figures, touched with great neatneſs, freedom, and ſpirit.

He had a peculiar mode of giving brilliancy to the eyes of his figures by a ſmart touch of pure white upon them, which diſtinguiſhes his pictures, and ſerves as a guide to the connoiſſeurs. The works of the father and the ſon are often confounded and miſtaken for each other, ſo ſimilar are they in conception and execution. Young Franck died in 1642, aged 62.

FRANCKEN, CHRISTIAN, a learned German unitarian divine, was born, about the middle of the ſixteenth century, at Gardleben, a town of Brandenburg. His parents were of the Lutheran perſuaſion, but he himſelf, at an early period of life, became a convert to popery, and entered the order of the Jeſuits in the year 1568. He was ſent to Rome to go through his noviciate, and, after ſpending ſome years in Italy, was recalled to Germany, where he manifeſted much zeal in oppoſing the heterodox doctrines that were then ſpreading in all directions. At Vienna he was appointed profeſſor of philoſophy, and in this ſituation he became convinced that the doctrines of popery were unſcriptural and highly erroneous, reſigned his office, and withdrew to his native town. He is ſaid after this to have been wavering as to the courſe he ſhould adopt, and deſirous of returning into the boſom of the church which he had juſt openly abandoned. At length, however, he joined himſelf to the unitarians in Poland, and became a ſtrenuous advocate for the opinions maintained by Francis David, and entered into a controverſy with Socinus on the ſubject. See DAVID. In 1584 he publiſhed an account of this diſpute, which was afterwards republiſhed by Socinus with notes, remarks, and many corrections. From this period to 1590, Francken was at the head of an unitarian ſeminary firſt at Chelmnitz, and afterwards at Tranſylvania. From this place he went to Prague, where he is reported to have returned again into the communion of the Catholic church. He next went to Ratiſbon, where he was patronized by Ladiſlaus Popelius, one of the emperor's officers, who was zealouſly attached to philoſophical purſuits. In this place, and under this protection, he publiſhed his "Analyſis Rixæ Chriſtianæ, quæ Imperium turbat, et diminuit Romanum." From this period we learn nothing more of him; he was author of many theological pieces, and of a ſevere ſatire on the Jeſuits, entitled, "Breve Colloquium Jeſuiticum, toti orbi Chriſtiano, ad recte cognoſcendam hactenus non ſatis perſpectam Jeſuitarum Religionem, utiliſſimum, habitum à Sacræ Theologiæ Doctore et Profeſſore Paulo Florenio cum Chriſtiano Francken, &c." Moreri. Toulmin's Life of Socinus.

FRANCKLIN, THOMAS, was born in London about 1720. He was educated at Weſtminſter, and at Trinity college Cambridge, where he diſtinguiſhed himſelf in his ſtudies. His father, as printer and publiſher of the Craftſman, was ſupported by Bolingbroke, Pulteney, and others, and from theſe he hoped for ſome proviſion for his ſon, but was diſappointed. The young man became fellow of his college, and was firſt known as an author in 1749, by a tranſlation of "The epiſtles of Phalaris," and of one of "Cicero on the nature of the Gods." In 1750, he was elected to the Greek profeſſorſhip in the univerſity of Cambridge; and, in 1758, he was preſented with the livings of Ware and Thunbridge in Hertfordſhire. In the following year he publiſhed one of his moſt conſiderable works, *viz.* "A Tranſlation of all the Plays of Sophocles," in two volumes 4to. which have ſince been printed in the octavo ſize. In 1767, he was nominated one of the king's chaplains, and took the degree of D. D. in 1770; he ſtill continued his literary occupations, and even wrote a farce for the ſtage; but the concluſion of his labours was a tranſlation of "The works of Lucian," in two vols. 4to. 1780, which is thought to give the Engliſh reader a good idea of the humour and vivacity of that celebrated writer. To this tranſlation was prefixed "A dialogue between Lucian and lord Lyttelton in the Elyſian Fields," intended as an account of the life and character of Lucian. In his latter years Dr. Francklin held the living of Bruſted in Kent. As a clergyman he was author of ſeveral ſingle ſermons; of a volume of "Diſcourſes on the Relative Duties;" and of "A letter to a biſhop concerning Lectureſhips," pointing out, in ſtrong terms, the diſgraceful ſteps that are often taken in procuring thoſe offices. Gen. Biog.

FRANCKS, or VRANX, JOHN BABTIST, a painter of hiſtory and converſations. He was born at Antwerp in 1600. At firſt he made the works of Vandyke and Rubens his ſtudy, but never ſucceeded to any high degree of excellence. He was moſt ſucceſsful in repreſenting interiors of galleries or grand apartments ornamented with ſtatues and pictures, with perſons engaged in different ways, either in converſation, play, or concerts of muſic. Theſe ſubjects he deſigned and executed extremely well, finiſhing them with a neat and agreeable pencil; but he was not ſufficiently ſkilful in the arrangement and due ſubordination of lights, ſo that his effects are frequently confuſed.

Houbraken deſcribes one of his works of this kind as being truly excellent. It repreſents the interior of a grand apartment or cabinet of a curious perſon, decorated with buſts and other ornamental furniture elegantly diſpoſed, with pictures arranged upon the wall; which are ſo admirably finiſhed, that the taſte of the maſters, whoſe works they are ſuppoſed to be, is diſtinguiſhable. There are only two figures in the apartment, which are portraits of Rubens and Vandyke engaged in playing at tables. The likeneſſes of theſe artiſts are greatly commended, and the delicacy of touch with which they are executed.

FRANCO, MAGISTER, ſcholaſtic of the cathedral of Cologne; a very important perſonage in the hiſtory of muſic, whoſe merit had lain dormant many ages buried in MSS. which had never entered the preſs, nor would it have been known to modern muſicians that he ever exiſted, but for the general reſearch in the principal libraries of Europe after materials for a general hiſtory of muſic.

Magiſter Franco is by ſome called a native, or at leaſt an inhabitant of Paris; by others a ſcholaſtic of Liege; but if we may believe Franco himſelf, he was of Cologne; for, ſeeming to foreſee the diſputes which would ariſe concerning his locality, he begins his "Compendium de Diſcantu," one of his muſical tracts which has been preſerved, in the following manner: "Ego Franco de Colonia, &c." which, if the

authors of the "Hiſtoire Litteraire de la France" had ſeen, they doubtleſs would not have fixed him at Liege, nor would thoſe who have implicitly followed them, have been led into this miſtake.

Sigebert tells us that Franco ſupported the functions of his office of ſcholaſtic, or preceptor, by a great fund of religion and knowledge: and acquired as much celebrity by his virtue as ſcience: "Scientia literarum et morum probitate clarus." He ventured, ſay the Benedictines, to ſtudy profane ſcience as well as eccleſiaſtic, and had the courage to attempt ſquaring the circle. Chriſtian philoſophers generally regard a man for loſt who addicts himſelf to ſuch purſuits as the ſquaring of the circle, the multiplication of the cube, perpetual motion, the philoſopher's ſtone, judicial aſtrology, or magic. But Franco is ſaid to have exerciſed his faculties in theſe ſtudies with ſuch diſcretion, that he never neglected his more important concerns.

By the teſtimony of Sigebert, his cotemporary, he had acquired great reputation for his learning in 1047. At leaſt it is certain that he had written concerning the ſquare of the circle before the month of February 1055, at which time Heriman, archbiſhop of Cologne, to whom he dedicated his work, died.

Franco lived at leaſt till Auguſt 1083, for he at that time filled the charge of ſcholaſtic of the cathedral of Liege.

Among many works which Franco is ſaid to have produced upon religious and mathematical ſubjects, we are told by the authors of the "Hiſtoire Litteraire de la France," that he wrote upon muſic and plain-chant; and that in the abbey of Lire in Normandy, there is a manuſcript in folio, which contains "Ars Magiſtri Franconis de Muſica Menſurabili." Theſe writers add, that there can be no doubt of this Magiſter Franco being the ſame as the ſcholaſtic of that name; or that another tract on muſic, in ſix chapters, entitled "Magiſtri Franconis Muſica," and preſerved in the Bodleian library at Oxford, is by the ſame author, as well as the "Compendium de Diſcantu, tribus capitibus," in the ſame library.

Theſe authors, who indeed pretend not to have ſeen the muſical tracts of Franco, have imagined, contrary to their uſual accuracy, that the treatiſe "De Muſica Menſurabili," in the library at Lire, and "Muſica Magiſtri Franconis," in the Bodleian library, were different works, but there remains not the leaſt doubt of their being duplicates of the ſame tract, in every reſpect, but their titles.

Trithemius, who calls him Franco Scholaſticus Leodienſis Eccleſiæ, of the church of Liege, natione Theutonicus, and a German, tells us, that "he was very learned in the holy ſcriptures; a great philoſopher, aſtronomer, arithmetician, (computiſta;)" and that he dedicated ſeveral of his works to the archbiſhop of Cologne: ſuch as his tract "De Quadratura Circuli;" "De Computo Eccleſiaſtico; et alia plura;" but he ſpecifies none of the muſical writings of Franco, who, according to this biographer, flouriſhed under the emperor Henry III. 1060.

The firſt mention however which we can find of Franco as a writer on muſic in any treatiſe on the ſubject is in the "Lucidarium in Arte Muſicæ planeæ," by Marchetto da Padova, written in the year 1274, who ſays that the agreement of different melodies, according to Magiſter Franco, conſtitutes diſcant ("diſcantus ſecundum Magiſtrum Franconem, eſt diverſorum cantum conſonantia. Ex. cod. Vatic. Num. 5322.") He likewiſe cites him in his "Pomœrium de muſica menſurata," as an *inventor* of the four firſt muſical characters. (Muratori Antiq. Med. Ævi Diſſert. 24. tom. ii. Padre Martini, tom. i. p. 189. Gerb. tom. ii. p. 124.) And this would have been ſufficiently early to have ſtript John de Muris of the honour of their invention, had he choſen to inveſt himſelf with it. He is next in point of time mentioned by John de Muris himſelf, and in a MS. of the Bodleian library (Digby 90) aſcribed to Thomas, or John of Tewkſbury, which, it is ſaid at the end, was finiſhed at the univerſity of Oxford, 1351. There is a chapter expreſsly on the muſical characters for time, invented by Franco: "De figuris inventis a Francone."

Franchinus Gaforius, Pract. Muſicæ, lib. ii. c. 5. quotes him twice as author of the time-table; and aſcribes to him, ib. lib. iii. c. 1. the completion of counterpoint, by his contrivance of moving in different melodies at the ſame time: meaning his invention of muſical characters for meaſure.

Our countryman Morley, Annotations to his Introduction, p. 7. ſays that "Franco was the moſt ancient of all thoſe whoſe works on practical muſic had come to his hands." But he ſeems only to have ſeen a commentary on his treatiſe by Robert de Handlo, and to know nothing of his age and country. Robert de Handlo wrote a commentary on the "Muſica Menſurabilis of Franco," 1326. (See Tanner, p. 376.) And this is even an earlier period than was aſſigned to the invention by thoſe who had given it to John de Muris. And Ravenſcroft, "Briefe diſcourſe of the true uſe of charactering the degrees in Meaſurable Muſicke, 1614," p. 1. who appears indeed to have been no better acquainted with the original than Morley, quoting him only through John Dunſtable, an Engliſhman, Id. p. 3. tells us boldly, that he was the inventor of the four firſt ſimple notes of menſurable muſic; but, unluckily, calls him Franchinus de Coloniâ, confounding him with Franchinus Gafurius.

Critical exactneſs, with reſpect to dates, names, or facts, was not yet much practiſed in writing upon the arts; and Morley, the beſt author who had written expreſsly on muſic, in our language, ſince the invention of printing, took many things upon truſt; and though he gave a long liſt of practical muſicians, whoſe works he had conſulted, he never had ſeen the writings of Guido, nor does he quote a ſingle manuſcript treatiſe throughout his introduction, which indeed is profeſſedly more didactic than hiſtorical.

We have been the more ſolicitous to eſtabliſh the exiſtence of Franco, and the time when he flouriſhed, as muſical writers have been ſo long in the habit of aſſigning to John de Muris the invention of the time table, or muſical notation, by copying each other without further enquiry, that they ſeem unwilling to ſtrip him of an honour which they themſelves have ſo gratuitouſly conferred upon him.

Having collected the evidence of reſpectable and unſuſpected writers in favour of the muſical tracts of Magiſter Franco, it will be neceſſary to give the reader an account of the particular treatiſes which chiefly concern the "Ars Cantus Menſurabilis:" and this we ſhall do from the work itſelf, of which we obtained a tranſcript from the Bodleian library at Oxford (842—49.)

This ſhort, but celebrated tract, contains ſix chapters: 1. Prologue, and definitions of the terms uſed in the treatiſe. 2. Of the figures, or repreſentations of ſingle ſounds. 3. Of ligatures, or compound notes. 4. Of reſts or pauſes. 5. Of the different concords uſed in diſcant. 6. Of the organum, and of other combinations of ſounds.

In ſpeaking of former muſical writers, he ſays, "that both the theory and practice of plain muſic, or chanting, had been ſufficiently explained by ſeveral philoſophers; particularly the theory by Boethius, and the practice by Guido," whom he exalts into a philoſopher. "The eccleſiaſtical tropes or modes," he adds, "had been ſettled by St. Gregory." Franco, therefore, only intends to

treat of meaſured muſic, of which, he pioufly obſerves, plain-chant has the precedence, as the principal of the ſubaltern. "Nor let any one ſay," continues he, "that I have undertaken this work through arrogance, or for my own convenience, but merely for the ſake of its evident truth, the eaſe with which it may be comprehended by the ſtudent, and its containing the moſt perfect method of teaching all the modes of meaſured muſic, and their notation. For as there are ſeveral authors, as well modern as ancient, who in their treatiſes give many good rules concerning meaſured muſic, and on the contrary are deficient and erroneous in other particulars, eſpecially in the appendages of the ſcience, we think their doctrines require ſome correction and improvement, leſt the ſcience itſelf ſhould ſuffer from their errors and defects. We therefore propoſe giving a compendious explanation of meaſured muſic, in which we ſhall not ſcruple to inſert *what others have ſaid well on the ſubject*, to correct their errors, and to ſupport by good reaſons *whatever we ourſelves may have newly invented.*"

It ſeems evident from this paſſage, particularly thoſe parts of it which are printed in italics, that the invention of muſical notes for time, is more ancient than Franco, and that he had only the merit of improvement. It likewiſe informs us, that there were, in his time, treatiſes "de Menſurabili Muſicâ," or, at leaſt, that doctrines had been propoſed and laid down concerning muſical notes, and the different duration of ſounds, by writers who were *antiqui*, with reſpect to him; and proves very ſtrongly that this manuſcript contains only a mixture of his own rules, with thoſe of his predeceſſors. And indeed, upon a careful analyſis of this whole tract, it does not appear that Franco was the inventor of muſical notes, or characters for time, though they have lately been given to him in ſuch very poſitive terms, by thoſe who, without ſeeing his manuſcript, have taken it for granted that it was wholly his property, becauſe no other writer of equal antiquity was found to have treated of cantus menſurabilis. Indeed, beſides the paſſages already cited, we find him ſpeaking of former writers, and former opinions concerning the notes and modes; particularly, chapter ſecond, the words *quemadmodum quidam poſuerunt*, acknowledge other writers upon the ſubject of meaſured muſic beſides himſelf; and, chapter the fourth, he ſpeaks of the great error which *ſome* have committed by tying together three *longs* in tenor parts; and of the ſtill greater blunder which *others* have made in tying a *long* between two breves. And the author of a Latin treatiſe, which was among the Cotton muſical manuſcripts, ſeems to determine with great preciſion the degree of merit that is due to Franco, with reſpect to the time-table; for ſpeaking of the canto fermo of an earlier period, he ſays: "Though muſic was at that time not meaſured, it was approaching *towards* meaſure, when Franco appeared, who was the firſt approved author, or writer, on meaſured muſic." After this introduction, definitions are given in which we ſhall mention whatever ſeems ſingular or curious. Meaſured muſic, he ſays, is regulated by long and ſhort times, or portions of meaſure; and meaſure he defines, the regulated motion of any ſeries of ſounds, whether quick or ſlow, different from plain-ſong, in which no ſuch regularity of movement is obſerved. A time is the ſtated proportion of a lengthened tone, or of a reſt of equal duration. "I ſpeak of a reſt," ſays he, "as meaſured by time, becauſe otherwiſe the performers of two different parts, one of which ſhould have a reſt, and the other not, would be unable to proceed together in exact time. This ſeems to be the purport of the original, which however we ſhall conſtantly throw into the notes for the conſideration of the curious and learned reader who may perhaps diſcover meanings which may have eſcaped our penetration. Indeed, this paſſage gives an idea of more than ſimple counterpoint, of note for note, and ſyllable for ſyllable, being practiſed in Franco's time, who is believed to have written his tract within fifty years of Guido.

"Meaſured muſic," continues he, "is of two kinds: wholly, and partly meaſured. Muſic wholly meaſured is diſcant, which is meaſured throughout; and that which is partly meaſured is the ſimple chant or plain-ſong, which, though meaſured by time in ſome degree, is neither organum nor diſcant, as it is commonly called by thoſe who ſing the eccleſiaſtical chants." "Dividitur autem menſurabilis muſica in menſurabilem ſimpliciter et partim. Menſurabilis ſimpliciter eſt diſcantus, eo quod in omni parte ſua menſuratur. Menſurabilis partim eſt cantus ſimplex et tempore menſuratus, ſed organum non eſt, neque diſcantus, (organum) communiter vero dicitur quibus cantus eccleſiaſticus tempore menſuratur."

It ſeems, by this paſſage, as if organizing, or ſinging in harmony, had firſt brought the *plain-chant* to *ſtrict time*; and that, then, when only a *ſingle* part or melody was ſung *in time*, it was cuſtomary to call it *organum*, becauſe *meaſured like* the *organum*. And perhaps, in ſinging upon a plain-ſong, the principal melody, while it continued to be chanted nearly in the ſame manner as it uſed to be before parts were added to it, was ſaid to be *partly meaſured*; and the organum or diſcant, moving in proportionate notes of different lengths, was regarded as *wholly meaſured*. In our cathedrals, where the pſalms are chanted in four parts, time is neither abſolutely kept, nor wholly diſregarded: it is kept with reſpect to the harmony, as all the parts move together; yet the melody of each part, being governed by the length of the verſes, cannot be ſaid to be regularly meaſured. In accompanied recitation the inſtruments move ſometimes *à tempo*, while the voice part ſeems *ad libitum*. He next defines *diſcant*, and, as the reader, curious in muſical hiſtory, may wiſh to know the acceptation of this term ſo near the time of its invention, we refer to the article DISCANT. He likewiſe defines *mood*, which ſee in its proper place. In his ſecond chapter, Franco treats of ſimple notes or characters, of which he enumerates only three kinds, the long, the breve, and ſemi-breve; (making no mention of the *large*, or the *minim*.) Theſe, he tells us, are either perfect or imperfect. The perfect long he calls the firſt and principal of all the notes, for in that all others are included. "The perfect note, he tells us, is that which is meaſured by three times, or portions; the ternary diviſion being the moſt perfect of all, as it had its name from the Holy Trinity, which is true and pure perfection."

The perfect long is repreſented by a ſquare, not with a tail on the right hand, deſcending, as thus:

This is equal to three breves. The imperfect long, repreſented by the ſame figure, is equal only to two. It is imperfect for the reaſon already aſſigned, ſays Franco, and can only acquire its full length by the addition of a breve before or after it. "Whence it follows," continues he, "that thoſe err who call it perfect; as that only is entire and complete which can ſtand by itſelf."

It ſeems by this paſſage as if there had been a controverſy even in Franco's time about the greater degree of perfection of triple, or common time; in after ages, however, the binary

binary number acquired the pre-eminence, and was called perfect, while the triple proportion was degraded into imperfect. The length of the notes, that is, the perfection or imperfection, triple or double powers, depended on their *poſition*. But to conclude this ſubject we plunge the reader into a ſea of trouble concerning diſtinctions about which our forefathers themſelves were not well agreed: and the rules of Franco on this ſubject are too numerous, complex, and uſeleſs to merit the reader's attention, or an attempt at explaining them. Indeed if they would help to decipher other muſic compoſed after the time of Franco, the curious enquirer's trouble and our own might be repaid, but there was at firſt ſo much confuſion in the moods, and ſo many and ſo dark were the exceptions to their rules, ſo numerous and jarring the opinions and deciſions concerning them, and ſo little agreed were muſicians about the different prolations, points of perfection and imperfection, of increaſe and diminution, diviſion and tranſlation, even in Morley's time, as gave occaſion to his ſaying, that "no two of them told the ſame tale."

FRANCO, NICHOLAS, born at Benevento in 1510, was ſon of a ſchoolmaſter, under whom he acquired a knowledge of the learned languages. In his youth he became acquainted with Peter Aretino, from whom he caught that ſpirit of ſatire which made him ſo many enemies, and which drove him from his own country to Venice, where Aretino then was. Their union was neither ſincere nor long lived. The ſucceſs of Aretino's letters excited the envy of Franco, who publiſhed, by way of rivalry, his "Piſtole Vulgari" in 1539. A fierce war was commenced between them, and ſuſtained on each ſide with the greateſt rancour and malignity. Franco left Venice and took up his abode at Montferrat, where he publiſhed a dialogue, entitled "Delle Belleze:" alſo a collection of ſonnets againſt Aretino with a "Priapeia Italiana," which contained the groſſeſt obſcenity, the moſt unqualified abuſe, and the boldeſt ſatire againſt princes, popes, the fathers of the council of Trent, and other eminent perſons. The licentiouſneſs of Franco did not injure his literary reputation; he was a principal member of the academy of Argonauti at Montferrat, and in this capacity wrote his "Rime Maritime," printed at Mantua in 1549. At Mantua he followed the profeſſion of a ſchoolmaſter, thence he removed to Rome, where he publiſhed commentaries on the "Priapeia," attributed to Virgil, the copies of which were ſuppreſſed and burned by order of pope Paul IV. Under Pius IV. he continued to indulge his virulence, but was preſerved from perſonal chaſtiſement by the protection of cardinal Morone. His imprudence however, in writing a Latin epigram againſt Pius V., with other deſamatory libels, brought upon him that puniſhment, which it ſeems extraordinary he ſhould ſo long have eſcaped. He was taken from his ſtudy in his furred robe, and hanged on the common gallows without trial or ceremony, which may and ought to prove a warning againſt the faults, the indiſcretions, and the vices to which talents, without principle and morality, are liable. He was author of ſeveral other works beſides thoſe already enumerated, and he left behind him in MS. a tranſlation of Homer's Iliad. An attempt has been made, in the "Annee Litteraire," to raiſe Franco to the dignity of a reformer of the corruptions of the age, on account of which he was ſingled out as a martyr to his heroiſm: but his writings will not juſtify the ſuppoſition. Moreri.

FRANCOA, in *Botany*, named by the late abbé Cavanilles, in honour of Francis Franco, a phyſician and botaniſt of Valentia, who lived about the middle of the 16th century, and taught phyſic at Alcala, Seville, and Coimbra. Cavan. Ic. v. 6. 76. Claſs and order, *Octandria Tetragynia*. Nat. Ord. uncertain.

Gen. Ch. *Cal.* Perianth inferior, permanent, in four deep, equal, lanceolate diviſions. *Cor.* Petals four, ovate-oblong, equal, narrow at the baſe. *Stam.* Filaments eight, awl-ſhaped, equal, ſhorter than the corolla, inſerted into the receptacle cloſe to the germen, accompanied by eight intermediate alternate glands between their baſes; anthers ovate, erect, of two cells. *Piſt.* Germen ſuperior, ſeſſile, ovate, with four deep furrows; ſtyles none; ſtigmas four, ſhort, ovate, flat, ſpreading. *Peric.* Capſule with four angles, and four deep intermediate furrows, of four cells and eight valves; or rather conſiſting of four bivalve capſules, compreſſed, and cohering by their inner margins. *Seeds* minute, numerous, oblong, rugged, ranged along the inner edge of the valves.

Eſſ. Ch. Calyx of four leaves. Petals four. Eight glands alternate with the ſtamens. Capſules four, bivalve, cohering by their inner edge. Seeds numerous.

1. F. *appendiculata*. Cav. Ic. v. 6. 77. t. 596.—Leaves lyrate, with diſtant lobes. Calyx and flower-ſtalks hairy. —Diſcovered by Louis Née in the fertile iſland of San Carlos de Chiloe, and other parts of Chili, flowering in February. *Root* ſpindle-ſhaped, perennial? *Stem* none. *Leaves* radical, deeply lyrate, wavy, crenate, downy, a ſpan long. *Flower-ſtalk* ſolitary, taller than the leaves, round, hairy, naked, ſimple or divided, racemoſe. *Flowers* leaning to one ſide, the ſize of Borage, of a pale roſe-colour, their calyx, ſtalks, and bracteas at the baſe of each partial ſtalk, villoſe. Sometimes the flowers are over luxuriant, or monſtrous. Each petal is marked with a deep-coloured ſpot.

2. F. *ſonchifolia*. Cav. Ic. v. 6. 77. (Llaupankè; Feuillée Plant. Med. 742. t. 31.)—Leaves lyrate, with imbricated lobes. Calyx and flower-ſtalks ſmooth.—Gathered by Feuillée on the mountains of Chili, latitude 36° 57 ſouth. This much reſembles the former, but the lobes of the *leaves* are repreſented as crowded and imbricated, and the *flowers* more numerous, crimſon, with a violet ſpot on each petal. The juice of the plant appears by Feuillée's account to be of an aſtringent quality, being uſed as an application to ſtop blood, and by the dyers to dye black.

Concerning the natural order of this genus, known to us only by the works of Cavanilles and Feuillée, we have no certain ideas. It ſeems allied to *Droſera*, whoſe affinity is itſelf obſcure.

FRANCOCCI, in *Geography*, a town of the duchy of Spoleto; ſeven miles W.N.W. of Spoleto.

FRANCŒUR, FRANCIS, in *Biography*, ſuperintendant of the king of France's band of muſic, born in 1698, was a profeſſor much reſpected by his countrymen. He connected himſelf in his earlieſt youth with M. Rebel, another reſpectable profeſſor, in ſo cloſe a friendſhip, that, like our Beaumont and Fletcher, they conſtantly ran the ſame courſe. Their intimacy was ſo perfect, that it was never known which was the author of the ſeveral pieces of their compoſition. In their early youth they played ſo agreeably on the violin, that they were only known by the title of the "little fiddlers." M. Francœur was admitted into the opera band in 1710, and ſoon after was appointed one of the king's chamber muſicians.

In 1724 he purchaſed the place of one of the twenty-four muſicians of the king's band on the eſtabliſhment, as well as the ſurvivorſhip of compoſer to his majeſty, to which he arrived in 1733. In 1736 Meſſrs. Rebel and Francœur were nominated inſpectors of the opera. In 1742 the latter purchaſed of M. Blamont the reverſion of the place of ſuperintendant or

maſter

maſter of the king's band, to which he ſucceeded in 1760. At length he became director and manager of the opera jointly with his friend Rebel, in 1757 to 1767, and was honoured with the order of St. Michael in 1764; and at the termination of this enterprize, the chevalier Francœur quitted all profeſſional concerns, and lived only for himſelf and his friends. At nearly 80 years of age he had the courage to be cut for the ſtone, and to ſuſtain that terrible operation, one of the longeſt and moſt difficult that ever was undertaken, it having been commenced three ſucceſſive days. His fortitude, and the cheerfulneſs of his character, ſupported him under ſuch dreadful circumſtances, and in a few days he was perfectly recovered. Poor Dr. Worgan, in our own country, ſunk under ſimilar ſufferings. M. Francœur publiſhed in his youth two ſets of ſonatas compoſed by himſelf alone; and in partnerſhip afterwards with M. Rebel, eight operas, which abound with melody and excellent recitative, and had no other defect than the being ſung too ſlow. Laborde.

Francœur, nephew of the preceding muſician, loſing his father during infancy, was adopted and educated by his uncle, and treated by him with all the care and tenderneſs of a father, and by his intereſt, and his own diligence and muſical talents, he ſucceeded to moſt of the appointments of his uncle. He was likewiſe a compoſer of operas, and leader of the opera band. By his probity, and the ſimplicity of his character, he had the honour of being diſtinguiſhed by the title of "honeſt Francœur" (Francœur l'honete homme.) He was author of a very uſeful tract to young muſical compoſers, under the title of "Diapaſon de tous les inſtrumens à vent," ſcale and compaſs of all wind inſtruments, 1772.

FRAN. OIS, in *Geography*, a town of Canada, on the eaſt coaſt of lake St. Pierre. N. lat. 46° 5'. W. long. 72° 36.

François, *Cape*. See Guarico.—Alſo, the northernmoſt point of Kerguelen's land.

François, *Old Cape*, a town and cape on the north coaſt of the iſland of Hiſpaniola. N. lat. 19° 40'. W. long. 70° 44'.

François, *Port des*. See Français.

François *River*, a river of Upper Canada, which runs S.W. from lake Nipiſſing into lake Huron; it has ſeveral portages: that neareſt to lake Nipiſſing is called Portage de Trois Chaudiers, about half a mile in length.

FRANCOISE, a ſmall iſland in the Atlantic, near the coaſt of Africa. N. lat. 20° 15'.

Françoise, *La*. See Française.

FRANCOLI, a river of Spain, which runs into the ſea near Tarragon, in Catalonia.

FRANCOLIN, in *Ornithology*, a ſpecies of *Tetrao*, which ſee.

FRANCOLINO, in *Geography*, a town of Italy, in the department of the Lower Po; eight miles N.E. of Ferrara.

FRANCONIA, a circle of Germany, bounded on the N. by Meiſſen and Thuringia, on the E. by Bohemia and the Upper Palatinate, on the S. by Bavaria and Swabia, and on the W. by the Lower Palatinate and the electorate of Mentz. The form of Franconia is ſomewhat circular, its diameter being about 150 miles; the land towards the centre is fertile in corn, wine, fruit, &c. but the frontiers are full of foreſts and mountains, and little cultivated. The chief river is the Mayne. The inhabitants of many towns are Roman Catholics, but the principal part conſiſts of Lutherans. The Calviniſts have ſome churches, and the Jews ſome ſynagogues. The ſtates compoſing this circle are partly eccleſiaſtical and partly civil. See Germany.

Franconia, a townſhip of America, in Grafton county, New Hampſhire, 14 miles N.E. of Haverhill on Connecticut river. It was incorporated in 1764, and firſt called Morriſtown. It contains 129 inhabitants.

FRANCOSO, a town of Portugal, in the province of Beira; 22 miles E. of Viſeu.

FRANCUCCI, Innocenzio, in *Biography*, an hiſtorical painter, born at Imola, and therefore known by the name of Innocenzio da Imola. He was one of the eſtabliſhers of the Bologneſe ſchool. He became a diſciple of Franceſco Francia in 1506; then paſſed ſome time with Albertinelli at Florence; and from the evidence of his works, and the teſtimony of Vaſari, ſtudied much after Fra. Bartolomeo and Andrea del Sarto: for though the main diſpoſition of his altar pieces be ſtill Gothic, he no longer uſed the ancient gilding; he placed the Virgin on high in the centre, and ſurrounded her with ſaints and angels, architecture, and back grounds ſkilfully grouped and arranged with novelty and taſte. Such is his ſtyle in the ſurprizing picture of the Duomo at Faenza, and in another at Peſaro. The aerial perſpective and back ground remind us of Leonardo da Vinci. He ſometimes placed ſmaller pictures under his altar pieces, like that at St. Giacomo of Bologna, which breathes the very ſpirit of Raffaello; that ſpirit he ſeems indeed to have aimed at in the greater part of his works, and to have approached it nearer than moſt of Raffaello's own ſcholars. He excelled Francia and his fellow ſcholar Bagnacavallo in erudition, majeſty, and correctneſs. Subjects of novel combination and fiery fancy he has not produced; nor ſeem they to have been congenial with that mildneſs and tranquillity of character which hiſtory aſcribes to him. Fuſeli's Pilkington.

FRANEKER, in *Geography*, a town of Holland, in Frieſland; watered by two canals, navigable for barges, and having a caſtle, built in the 15th century, and a celebrated univerſity, eſtabliſhed by the ſtates and William Louis comte of Naſſau, in the year 1585. This is one of the neateſt towns in Frieſland, and has commonly been the reſidence of the nobleſſe of the country. The mean temperature of this town, during five years, was 52° 6'. The greateſt uſual cold is 12°, and the greateſt heat 82°. The ſtandard temperature of its latitude is 50° 2', the difference being 2° 4': the reaſon of which, according to Kirwan, is, that all continents, if flat, are in ſummer much warmer than the ſtandard, and particularly thoſe which border on the German ſea, as that ſea is, upon an average of the whole year, two degrees warmer than the Atlantic; but in winter the German ſea is colder than the ſtandard, and Holland, in general, is much expoſed to N.E. Siberian winds. N. lat. 53. E. long. 5° 42.

FRANGIPANE, an exquiſite kind of perfume, frequently given to the leather whereof gloves, purſes, bags, &c. are made.

It takes its name from a Roman nobleman, of the ancient family of Fragipani, who was the inventor of it.

There is alſo a kind of perfumed liquor of the ſame denomination, ſaid to have been invented by a grandſon of Mutio Frangipani; and alſo a perfumed kind of *ros ſolis*, called by the ſame name.

FRANGULA, in *Botany*, ſo called from *frango*, to break, on account of the brittleneſs of its branches; the berry-bearing alder, *Rhamnus Frangula*; Engl. Bot. t. 250. (See Rhamnus.) The berries are often ſold mixed with thoſe of buckthorn, R. *catharticus*, with which they nearly agree in quality. If it be any object to diſtinguiſh them,

thoſe of the *Frangula* may be known, as remarked in Lewis's Diſpenſatory, by having two ſeeds only, inſtead of four.

FRANGY, in *Geography*, a town of France, in the department of Geneva, and chief place of a canton in the diſtrict of Leman. The place contains 814, and the canton 7,535 inhabitants, on a territory of 175 kiliometres, in 24 communes.

FRANI, a town of Italy, in the department of the Adda and Oglio; two miles S.W. of Breno.

FRANK, or FRANC, a term literally ſignifying free and open, or exempt from public impoſitions and charges; as frank confeſſion, frank fair, frank letter, &c.

The term frank is much uſed in our ancient cuſtoms and tenures, where it receives various particular modifications and meanings, according to the words it is combined with, as

FRANK *Allen*, or *allodium*, is a land, tenement, or demeſne, that is not held of any ſuperior lord.

FRANK *Almoign*, or *free alms*, is a tenure of lands or tenements beſtowed on God; that is, given to ſuch people as devote themſelves to the ſervice of God, in pure and perpetual alms; or, it is a tenure, whereby a religious corporation, aggregate or ſole, holdeth lands of the donor, to them and their ſucceſſors for ever.

Whence the feoffors or givers cannot demand any terreſtrial ſervice, ſo long as the land remains in the hands of the feoffees.

The ſervice which the feoffees were bound to render for theſe lands is not certainly defined; but only in general, to pray for the ſouls of the donor and his heirs, dead or alive; and, therefore, they do no fealty, which is incident to all other ſervices but this, becauſe this divine ſervice was of a more exalted nature. (Litt. § 131. 133. 135.) This is the tenure by which all the ancient monaſteries and religious houſes held their lands; and by which the parochial clergy, and many eccleſiaſtical and eleemoſynary foundations hold them at this day. (Bracton, l. 4. tr. 1. c. 28. § 1.) This was an old Saxon tenure, and continued under the Norman revolution, on account of the reſpect ſhewn to religion and religious men in ancient times; and for this reaſon, tenants in frank-almoign were diſcharged of all other ſervices, except the *trinoda neceſſitas*, of repairing the highways, building caſtles, and repelling invaſions. (Seld. 1. 42.) And this tenure is ſtill diſtinct from all others, being not in the leaſt feodal, but merely ſpiritual; for, if the ſervice be neglected, the law gives no remedy by diſtreſs or otherwiſe to the lord of whom the lands are holden; but merely a complaint to the ordinary or viſitor to correct it. (Litt. § 136.)

Britton mentions another kind of land given in alms, but not free alms; the tenants being tied in certain ſervices to the feoffor; as to ſing ſo many maſſes, diſtribute ſuch a ſum in alms, and the like; and this tenure by divine ſervice differs from the former, becauſe for this, unperformed, the lord might diſtrain, without any complaint to the viſitor. (Litt. § 137.) All ſuch donations are now out of uſe; for ſince the ſtatute of *quia emptores*, 18 Edw. I. none but the king can give lands to be holden by this tenure. (Litt. § 140.) Theſe donations are expreſsly excepted, by name, in the ſtat. 12 Car. II. c. 24. aboliſhing tenures, and therefore ſubſiſt in many inſtances at the preſent day. See MORTMAIN.

FRANK *Bank*. See FREE *bench*.

FRANK *Chaſe* denotes liberty of free chaſe, in a circuit adjoining to a foreſt, on account of which men, though they have land of their own within that compaſs, are forbidden to cut down wood, without the view of the foreſter; though it be their own demeſne. See CHASE.

FRANK *Fee*, *feudum francum*, as defined by Brook, is that which is in the hands of the king or lord of the manor; being ancient demeſne of the crown.

FRANK *Fee*, *feudum liberum*, according to ſome, denotes that for which no ſervice is performed to any lord.

According to Fachin, lib. vii. cap. 39. lands held in frank fee were exempted from all ſervices, except homage; in contradiſtinction to that in the tenant's hands, which is only ancient demeſne.

In the reg. of writs, frank fee is ſaid to be that which a man holds at common law to him and his heirs; and not by ſuch ſervice as is required in ancient demeſne, according to the cuſtom of the manor.

It is added, that the lands in the hands of king Edward the Confeſſor, at the making of Domeſday-book, were ancient demeſne; and all the reſt frank fee. On which footing, all the lands in the realm are either ancient demeſne, or frank fee.

Others define frank fee to be a tenure in fee ſimple, or lands pleadable in common law; and not in ancient demeſne. See DECEIT and FEE.

FRANK-*ferme*, *firma libera*, denotes lands or tenements, wherein the nature of the fee is changed by feoffment, from knight's ſervice to a certain yearly ſervice; and whence neither homage, wardſhip, marriage, nor relief, may be demanded, nor any other ſervice not contained in the feoffment. See FEE-*farm* and SOCAGE.

FRANK-*fold* is where the lord hath the benefit of folding his tenant's ſheep, within his manor, for the manuring of his land.

FRANK *Language*, or *lingua Franca*, is a kind of jargon, ſpoken on the Mediterranean, and particularly throughout the coaſts and ports of the Levant, compoſed of Italian, Spaniſh, French, vulgar Greek, and other languages.

The lingua Franca is the trading language; and is thus called from the Franks, a common appellation given in the Levant to all the European merchants and traders who come thither to traffick.

In this language, if it may be ſo called, nothing but the infinitive mood of each verb is uſed; this ſerving for all the tenſes and moods of the conjugation; and yet this lame, mutilated diction, this barbarous medley, is learnt and underſtood by the merchants and mariners of all nations who repair thither.

FRANK *Law*, *lex libera*, is the benefit of the free and common law of the land.

He that for any offence, as conſpiracy, &c. loſeth his frank law, incurs theſe inconveniences: 1. That he may not be impanelled on any jury or aſſize; or otherwiſe uſed as an evidence or witneſs to the truth. 2. That if he have any thing to do in the king's courts, he muſt not approach them in perſon, but appoint his attorney. 3. That his lands, goods, and chattels, be ſeized into the king's hands; and the lands be eſtreated, his trees rooted up, and his body committed to cuſtody.

FRANK *Letters*, or *letters free of poſtage*. The privilege of ſuch letters was claimed by the houſe of commons in 1660, when the firſt legal ſettlement of the preſent poſt office was made; but afterwards dropped on a private aſſurance from the crown, that this privilege ſhould be allowed the members. Accordingly, a warrant was conſtantly iſſued to the poſtmaſter general, directing the allowance thereof to the extent of two ounces in weight; till at length it was expreſsly confirmed by ſtat. 4 Geo. III. cap. 24. which adds many new regulations, rendered neceſſary by the abuſes crept into the

practice

practice of franking; whereby the annual amount of franked letters had gradually increaſed from 23,600*l.* in 1715, to 170,700*l.* in 1763.

By other ſubſequent regulations it is required that franks ſhould be dated, with the month, &c. written at length, and put into the office the ſame day. The following reſtrictions and orders are enjoined by 35 Geo. III. now in force; no letter, directed to or by any member of parliament, ſhall be exempted from poſtage, if it exceeds one ounce in weight. No letter directed by any member ſhall be exempted, unleſs he ſhall actually be in the poſt-town, or within the limits of its delivery of letters, or within twenty miles of ſuch poſt-town, on the day, or on the day before the day, on which the letters ſhall be put into the office. No member ſhall be entitled to ſend free from poſtage more than ten letters in one day, nor to receive more than fifteen. Whenever the number of letters ſent or received by ſuch members in one day ſhall exceed the number exempted, the letters chargeable with a higher poſtage ſhall be included in the number exempted, in preference to any chargeable with a lower poſtage, and the remainder ſhall be chargeable with the poſtage to which common letters are ſubject. Perſons who may now in right of their offices ſend and receive letters free, may continue ſo to do. Printed votes, or proceedings in parliament, and printed newspapers, may alſo be ſent as uſual.

No ſingle letter ſent by the poſt from any non-commiſſioned officer, ſeaman, or private, in the navy, army, militia, fencible regiments, artillery or marines, ſhall be charged with more poſtage than one penny; but the ſame muſt be paid at the time of putting the ſame into the poſt-office; and ſuch letter muſt have written thereon, in the hand writing of, and ſigned by the commanding officer, the name of ſuch commanding officer, and of the ſhip, veſſel, corps, regiment, or detachment. Alſo no ſingle letter directed to any ſuch non-commiſſioned officer, ſeaman or private, ſhall be charged with more poſtage than one penny, to be paid on the delivery thereof; but ſuch letter muſt be directed to ſuch perſons, ſpecifying the ſhip, veſſel, regiment, troop, corps, company or detachment to which they belong; and the poſt-maſter muſt deliver ſuch letter either to the party to whom it ſhall be directed, or to ſome perſon appointed to receive the ſame by the commanding officer, and to no other.

Every cover containing patterns or ſamples of goods, not exceeding one ounce, ſhall be charged only as a ſingle letter, if ſent open at the ſides, and without any letter or writing therewith, other than the name of the perſon ſending the ſame, the place of his abode, and the prices of the articles. See POST-OFFICE and REVENUE.

FRANK *Marriage*, *liberum maritagium*, is a tenure in tail ſpecial; whereby lands and tenements are held to a perſon and his wife, and the heirs of their bodies, on condition of doing fealty to the donor, till the fourth degree of conſanguinity between the iſſues of the donor and donee.

Fleta gives this reaſon, why the heirs do no ſervice till the fourth degree: "ne donatores, vel eorum hæredes, per homagii receptionem a reverſione repellantur;" and why, in the fourth deſcent, they ſhall do ſervice to the donor, "quia in quarto gradu vehementer preſumitur quod terra eſt pro defectu hæredum donatorum reverſura."

Frank marriage is expreſſed by Bracton, to be that where the donor intends that the land thus beſtowed ſhall remain quiet, and free from all ſecular ſervice that might be annexed to the fee; ſo that he who gave it ſhall claim no manner of ſervice from it, until the third heir, and the fourth deſcent, or degree; reckoning the donee in the firſt degree, his heir in the ſecond, the heir of him in the third, and his again in the fourth; but afterwards the ſame land to become ſubject to all the former ſervices; as being then ſuppoſed to revert to the lord, for want of heirs.

The lands otherwiſe given in marriage, viz. *ſervitio obligatæ*, were with a reſervation of the ſervices due to the lord, which the donee and his heirs were bound to perform for ever: only homage was not to commence till the fourth degree, when both ſervice and homage were to be enjoined for ever.

A gift of lands by one man to another with a wife in frank-marriage amounts by implication of law to a gift in tail; which in this caſe may be created without the words "heirs" or "body." (Litt. 17. Wood's Inſt. 120.) A gift in free-marriage might be made as well after as before marriage; and ſuch a gift was a fee-ſimple before the ſtatute of Weſtm. 2.; but ſince, it is uſually a fee-tail. Although this tenure is now grown out of uſe, it is ſtill capable of ſubſiſting in law. It is liable to no ſervice but fealty.

FRANK-*pledge* ſignifies a pledge or ſurety for the behaviour of a freeman; called alſo *friburgh*.

The ancient cuſtom of England, for the preſervation of the public peace, was, that every free-born man, at fourteen years of age (religious perſons, clerks, knights, and their eldeſt ſons, excepted) ſhould find ſurety for his truth towards the king and his ſubjects, or elſe to be kept in priſon.

Accordingly, a number of neighbours became interchangeably bound for each other, to ſee each man of their pledge forthcoming at all times; or to anſwer for the offence committed by any one gone away; ſo that whenever one offended, it was preſently inquired in what pledge he was, and then thoſe of that pledge either brought him forth within one and thirty days to his anſwer; or they ſatisfied for his offence.

This cuſtom was called frank-pledge; and the circuit it extended to *decenna*, becauſe it uſually conſiſted of ten houſholds; and every perſon thus bound for himſelf and neighbours was called a *decennier*. See DECENNARY, DECINERS, and TITHING.

In obſervance of this cuſtom, the ſheriffs at every county-court did from time to time take the oaths of young perſons, as they arrived at the age of fourteen; and ſee they were ſettled in one *decenna* or *dozein*, or another; whereupon this branch of the ſheriff's office and authority was called *viſus franci plegii*, i. e. *view of frank-pledge*. See COURT-LEET.

"Omnis homo, ſive liber ſive ſervus, aut eſt, vel debet eſſe, in franco plegio, aut de alicujus manupaſtu, niſi ſit aliquis itinerans de loco in locum, qui non plus ſe teneat ad unum quam ad alium, vel qui habet quod ſufficiat pro franco plegio, ſicut dignitatem, vel ordinem, vel liberum tenementum, vel in civitate rem immobilem, &c." Bracton, lib. iii. Tract. de Corona, cap. 20.

At this day no man ordinarily gives any other ſecurity for the keeping of the peace, beſides his own oath; ſo that no one anſwers for the tranſgreſſion of another, but every perſon for himſelf. 4 Inſt. 76.

FRANK *Service*. See SERVICE.

FRANK *Tenement*. See TENEMENT, and FREEHOLD.

FRANK, or *Franc*, alſo denotes an ancient coin, ſtruck, and current in France; thus called from its impreſſion, which repreſented a Frenchman, ſometimes on horſeback, and ſometimes on foot.

The frank was either of gold or ſilver: the firſt was worth ſomewhat more than the ecu d'or, or gold crown. See CROWN.

The ſecond was a third of the firſt; but theſe coins have been long diſuſed.

The term frank, however, is ſtill retained as the name of a money of account. In this ſenſe it is equivalent to a livre, or twenty ſols, or a third of a French crown. See EXCHANGE.

FRANKENAU, in *Geography*, a town of Germany, in the principality of Hohenlohe; 12 miles N. of Dinkelſbahl.—Alſo, a town of Germany, in the principality of Heſſe; 24 miles S.W. of Caſſel.

FRANKENBERG, an ancient town of Germany, in the circle of Erzgeburg, on the Tſchopa; fortified againſt the Saxons by Charlemagne; 7 miles N.N.E. of Chemnitz. N. lat. 50° 50′. E. long. 12° 59′.

FRANKENDAL, or FRANKENTHAL, a town of France, in the department of Mont Tonnerre, and chief place of a canton, in the diſtrict of Spire, ſituated on a fertile plain, on a navigable canal which communicates with the Rhine. It originated with two convents, one for men and the other for women; and by the acceſſion of ſome Flemings, who, flying from perſecution, ſettled here, it became a flouriſhing town: but it felt the miſeries of war in common with the reſt of the Palatinate in the 17th century, but was afterwards rebuilt in a regular and handſome manner. The inhabitants are engaged in manufactures of porcelain, cloth, ſerges, ſilk, ſtuffs, ſtockings, ſoap, &c. In 1793 it was taken by the French. It contains three churches and an hoſpital. In the town are reckoned 3,235, and in the canton 11,381 inhabitants, in 17 communes; 8 miles S. of Worms.

FRANKENFELS, a town of Auſtria, ſeated on the river Noderſpach; 36 miles W. of Vienna.

FRANKENHAUSEN, a town of Germany, in the principality of Schwartzburg-Rudolſtadt, divided into the old and new town, ſituated on a branch of the Wipper. It contains three churches, and a ſchool, which was formerly a Ciſtercian convent; with profitable ſalt-works, belonging to the citizens; 26 miles N. of Erfurt. N. lat. 51° 16′. E. long. 11° 10′.—Alſo, a town of Germany, in the circle of Erzgeburg; 8 miles N.N.W of Zwichau.

FRANKENHEIM, a town of Germany, in the county of Henneberg; 14 miles W. of Meinungen.

FRANKENIA, in *Botany*, ſo named by Linnæus in memory of his predeceſſor John Franck, or Franckenius, profeſſor of botany and anatomy at Upſal, who died in 1661, at the age of 71. He publiſhed a catalogue of plants with Latin and Swediſh names, under the title of "Speculum Botanicum," which went through two editions, and is now equally rare and uſeleſs. We have alſo an inaugural diſſertation under his preſidency in 1633, by Hernodius, on the virtues of Tobacco, which are therein highly extolled, and a ſmall German work on the Materia Medica, printed at Roſtock in 1619, in quarto. This ſame genus was originally called *Franca* by Micheli, after Dr. John Sebaſtian Franchi, of Lucca, who practiſed phyſic with great reputation at Florence, and was one of the founders of the Botanical Society of that place. If what Micheli ſays of him be true, which no one can doubt, he deſerved commemoration as much as Frankenius, whoſe laurels have thus been grafted on his ſtock.—Linn. Gen. 176. Schreb. 234. Willd. Sp. Pl. v. 2. 241. Sm. Fl. Brit. 387. Mart. Mill. Dict. v. 2. Juſſ. 303. (Franca; Mich. Gen. 23. t. 22. Nothria; Berg. Cap. 171.)—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Caryophylleæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, funnel-ſhaped, ſomewhat cylindrical, ten-ſided, permanent, with five, rarely four, ſharp ſpreading teeth at the orifice. *Cor.* Petals five, rarely four, their claws the length of the calyx; limb flat, roundiſh, ſpreading. Nectary? a linear, channelled, pointed, parallel ſcale, inſerted into the claw of each petal. *Stam.* Filaments ſix, the length of the calyx; anthers roundiſh, two-lobed. *Piſt.* Germen oblong, ſuperior; ſtyle ſimple, the length of the ſtamens; ſtigmas three, oblong, erect, obtuſe. *Peric.* Capſule oval, of one cell and three valves. *Seeds* numerous, ovate, minute.

Eſſ. Ch. Calyx five-cleft, funnel-ſhaped. Petals four or five, with a ſcale upon each claw. Stigmas three. Capſule ſuperior, of one cell and three valves.

1. F. *lævis*. Smooth Sea-Heath. Linn. Sp. Pl. 473. Engl. Bot. t. 205. (Franca maritima ſupina ſaxatilis glauca ericoides ſempervirens, flore purpureo; Mich. Gen. 23. t. 22. f. 1.)—Leaves linear, cluſtered, ciliated at the baſe. Stem nearly ſmooth.—Found on the ſea coaſts of the ſouthern parts of Europe in a muddy ſoil, flowering in July. The *root* is perennial and woody. *Stems* procumbent, branched, forked, leafy, round, perennial, ſmooth or nearly ſo, except the young branches, which are downy. *Leaves* cluſtered, on ſhort ſtalks, oblong, revolute, pointed, glaucous, ſmooth; fringed at the baſe. *Flowers* ſolitary, ſeſſile, either in the forks of the ſtem or at the ends of the branches. They reſemble thoſe of a *Lychnis* in miniature, and are uſually pink; Micheli ſays they are ſometimes white.

F. *Nothria*. Thunb. Prod. 58. Willd. Sp. Pl. v. 2. 242. (Nothria repens; Berg. Cap. 171. t. 1. f. 2.); is certainly the ſame plant, and not even a variety, though a native of the Cape of Good Hope. The character of the ſharp petals, given by Willdenow, is merely taken from Bergius's figure, which is faulty. He himſelf deſcribes them rounded and obtuſe, as we find them in a Cape ſpecimen. Neither Bergius nor Thunberg ſeems to have known any thing of *Frankenia lævis*, or the latter would ſcarcely have made of it a new ſpecies, nor the former a new genus.

2. F. *hirſuta*. Hairy Sea-Heath. Linn. Sp. Pl. 473. Sm. Prodr. Fl. Græc. Sibth. v. 1. 243. (Franca maritima ſupina multiflora candida, caulibus hirſutis, foliis quaſi vermiculatis; Mich. Gen. 23. t. 22. f. 2.)—Leaves linear, cluſtered, ciliated at the baſe. Stem hairy.—Native of the ſea-coaſts of Italy, Barbary, Greece and the Archipelago, in moiſt places, flowering in July. We can ſcarcely think this more than a hairy and rather luxuriant variety of the former. The character of the flowers growing in terminal cluſters, taken by Linnæus from Micheli's plate, does by no means hold good, though the abundance of bloom on luxuriant ſpecimens gives them that appearance. They are produced from the forks of the *ſtem*, as well as from the ends of the branches, and it is only when thoſe branches are ſhort, and frequently forked, that the *flowers* acquire a cluſtered aſpect. The *leaves* ſeem to become more glaucous in proportion as the plant is more luxuriant.

Theſe are pretty plants, but extremely difficult of culture. The *Arenaria rubra*, ſo common on our ſandy heaths and ſea ſhores, is no mean imitation of them.

3. F. *microphylla*. Small-leaved Sea-Heath. Cav. Ic. v. 6. 77. t. 597. f. 1.—Leaves elliptical, revolute, ſmooth, imbricated in four rows. Stem ſmooth. Petals crenate.—Gathered by Louis Née at Port Deſire in South America, flowering in December. The *ſtems* are ſhrubby, much branched, decumbent, ſcarcely ſix inches long, ſmooth like every other part of the plant. *Leaves* oppoſite, united at the baſe, imbricated in four rows, ſmall, elliptical, entire, revolute, naked, concave underneath. *Flowers* terminal, ſolitary, ſeſſile, erect, whitiſh; the petals dilated and crenate at the extremity.

We know this only by Cavanilles' deſcription and figure,

which leave no doubt of its being diſtinct from both the preceding, of which its ſmooth naked imbricated leaves afford a deciſive mark.

4. F. *tetrapetala*. Four-petalled Sea-Heath. Billard. Nov. Holl. v. 1. 88. t. 114.—Leaves awl-ſhaped, fleſhy, dotted, ſmooth, oppoſite, ſpurred at the baſe. Petals four, obtuſe.—Gathered by Billardiere in Van Diemen's land. The *ſtems* are ſhrubby, proſtrate, apparently ſmooth, longer than the laſt, throwing up numerous ſhort, erect, ſimple or divided, leafy branches. *Leaves* oppoſite, ſomewhat imbricated, dotted with glandular pores, awl-ſhaped, with a longitudinal furrow on the upper ſide. *Flowers* terminal, ſolitary, ſeſſile. Segments of the *calyx* deep, downy at the edge, four only in number as well as the *petals*. The *ſtamens* and *piſtils* however are each of the number proper to the genus. Nothing is ſaid of the colour of the flowers, for though M. La Billardiere gathered them freſh, it appears from this and other inſtances, that his deſcriptions and figures were generally made from the dried ſpecimens after his return to Europe. Their accuracy therefore confers the more honour on their author.

5. F. *pulverulenta*. Powdery Sea-Heath. Linn. Sp. Pl. 474. Sm. Fl. Brit. 388. Hudſ. 138. Sm. Prodr. Fl. Græc. Sibth. v. 1. 243. (Franca maritima quadrifolia annua ſupina, chamæſyces folio et facie, flore ex albo purpuraſcente; Mich. Gen. 23. Alſine maritima ſupina, foliis chamæſyces; Dill. in Raii Syn. 352. Quadrifoglio annuo, piante di Perſia; Zannon. Iſt. 164. t. 66.)—Leaves obovate, abrupt, downy and powdery beneath.—Native of ſea-ſhores throughout the ſouth and eaſt of Europe, flowering in July. Dillenius and Hudſon report that it grows in Suſſex, but we have never ſeen an Engliſh ſpecimen. The *root* is annual. *Stems* numerous, proſtrate, repeatedly forked and divaricated, nearly ſmooth, except the oppoſite ſides of the young branches. *Leaves* oppoſite, two pair at every joint, nearly ſeſſile, obovate, entire, very obtuſe, ſomewhat revolute, ſmooth and green above, downy and rather powdery beneath. *Flowers* axillary and terminal, pale purple, with rounded crenate petals.—Micheli erroneouſly makes two ſpecies of this, ſuppoſing Zannoni's plant different from his own.

It is obſervable in this genus that the number of the ſtamens, ſix, bears an analogy to the three ſtigmas and three valves of the capſule, and not to the petals, nectaries, or ſegments of the calyx, which are each uſually five. This is a rare inſtance in nature, but not unique in the natural order to which it belongs, ſeveral of the genera of which have three ſtamens in a five-cleft flower.

FRANKENSTEIN, in *Geography*, a town of Sileſia, in the principality of Munſterburg, on the river Bautze; 12 miles S.S.W. of Glatz. N. lat. 51° 25'. E. long. 16° 42'.—Alſo, a town of Germany, in the circle of the Upper Rhine; 5 miles S.E. of Darmſtadt.—Alſo, a town of France, in the department of Mont-Tonnerre; 20 miles S.E. of Deux Ponts.

FRANKENWINHEIM, a town of Germany, in the principality of Wurzburg; 4 miles S.W. of Geroltzhoſen.

FRANKERAU, a town of Pruſſia, in the province of Ermeland; 10 miles S. of Heilſberg.

FRANKFORT. See FRANCFORT.

FRANKFORT, a poſt-town of America, in Hancock county, and ſtate of Maine, on the W. ſide of Penobſcot bay, 8 miles W. of Penobſcot; containing 867 inhabitants.

FRANKFORT, or *Frankford*, a pleaſant thriving village of America, in the county of Philadelphia and ſtate of Pennſylvania, on the N.E. ſide of a creek of the ſame name, 1½ mile from Delaware river, containing 100 houſes, an epiſcopal, and a German church; about 5 miles N.E. of Philadelphia.—Alſo, a new townſhip in Herkemer county, New York, E. of Whiteſtown; containing 946 inhabitants.—Alſo, a thriving village in Hampſhire county, Virginia, ſeated on a creek which empties itſelf into Potowmack river; 13 miles N.W. of Rumney.—Alſo, the capital of Pendleton county, Virginia, ſituated on the W. ſide of Potowmack river, containing a court-houſe, gaol, and about thirty houſes; 180 miles N.W. of Richmond.—Alſo, a poſt-town, and the metropolis of Kentucky, ſituated in Franklin county, on the N.E. bank of Kentucky river, about 50 miles from its confluence with the Ohio. It is a flouriſhing town, regularly laid out, and has a number of good houſes. The ſtate-houſe is a handſome building. It contains 628 inhabitants. N. lat. 38° 14'. W. long. 95° 28'.

FRANKINCENSE, or ſimply *Incenſe*, an odoriferous aromatic gum, or reſin, anciently burnt in temples, as a perfume, and now uſed in pharmacy, as an agglutinant and ſtrengthener.

The word is formed from the Latin *incenſum*, *burnt*; as alluding to its ancient uſe in temples.

Frankincenſe diſtils from inciſions made in a tree called *arbor thuriſera*, during the heats of ſummer. But notwithſtanding the great uſe of this gum, both in the ancient religion, and the modern medicine, the tree that produces it, or even the place where the tree grows, has been but little known.

The moſt common opinion has always been, that it was brought from Arabia Felix, and was found near the city of Saba; whence its epithet *Sabæum*; and yet the name *olibanum*, which it ſometimes alſo bears, ſeems to intimate, that there are of theſe thuriferous or incenſe-bearing trees in the Holy-land, near mount Lebanon. And travellers are poſitive that there are others in the Eaſt Indies.

Nor are we leſs at a loſs as to the form or kind of the tree from which it flows. Pliny contents himſelf to ſay, that it at firſt reſembles the pear-tree; then the maſtich-tree; then the laurel; but that in reality it is a kind of turpentine-tree. This gummy reſinous ſubſtance is ſaid to ooze ſpontaneouſly from the bark of the *Juniperus lycia*, appearing in drops or tears, of a pale yellowiſh, and ſometimes of a reddiſh colour.

Frankincenſe is uſually divided into male and female.

The beſt *male incenſe*, *thus maſculum*, called alſo *olibanum*, (which ſee,) is in fair white bits or tears, a little yellowiſh, of a bitter diſagreeable taſte; and when chewed it promotes the flux of ſaliva, which becomes white. When laid on coals, or a red-hot iron, it flames and burns with a ſtrong and not unpleaſant ſmell. On trituration with water, the greateſt part diſſolves into a milky liquor, which depoſits a reſinous matter, and, being gently inſpiſſated, leaves a yellow extract, retaining the greateſt part of the ſmell as well as taſte of the olibanum. Rectified ſpirit diſſolves leſs than water; nevertheleſs it extracts nearly all its active matter.

This drug has received different appellations according to its different appearances: the ſingle tears are called ſimply *olibanum*, or *thus*; when two are joined together, *thus maſculum*; and when two are very large, *thus femininum*; if ſeveral adhere to the bark, *thus corticoſum*: the fine powder which rubs off from the tears is denominated *mica thuris*; and the coarſer *manna thuris*.

That brought from the Indies is not near ſo good as that from Arabia or mount Lebanon; it is ſometimes called incenſe of Mocha; though it be not brought from that city.

It is often in a maſs, but ſometimes in looſe drops or tears; ſomewhat reddiſh, and bitter to the taſte. Some ſell this for the true bdellium.

Male incenſe, or *olibanum*, was formerly an ingredient in divers Galenical and chemical preparations: and was uſed, not only in divers diſeaſes of the head and breaſt, but in vomitings, diarrhœas, and dyſenteries. The doſe was from a ſcruple to a dram or more. Externally, it was applied to ſtrengthen the brain, and heal wounds. Some uſed it to aſſuage the tooth-ach; but it is apt to ſpoil the good teeth. Riverius found it of great efficacy in pleuriſies, which were ſaid to be epidemic; and Geoffroy likewiſe experienced its ſucceſs in theſe diſeaſes, eſpecially after veneſection. At preſent, however, recourſe is ſeldom had to this medicine, which is now ſuperſeded by myrrh, and other articles of a leſs ſtimulating kind.

As for female incenſe, or frankincenſe, authors deſcribe it to be ſofter, and more reſinous, but of leſſer virtue than the former. This common frankincenſe is brought to us in little globes or maſſes, of a browniſh or yellowiſh colour on the outſide, internally whitiſh, and variegated with whitiſh ſpecks. This reſin has a bitteriſh, acid, unpleaſant taſte, and no conſiderable ſmell; it diſſolves totally in rectified ſpirit, but is ſcarcely acted upon by watery menſtrua. It may be looked upon as a mild corroborant; though at preſent it is little otherwiſe made uſe of than as an ingredient in theriaca, and externally in plaſters. Lewis, Mat. Med.

Bark of incenſe, *cortex thuris*, is the bark of the tree whence the incenſe flows, which has the ſame qualities with the incenſe itſelf.

There is another bark brought from the Indies, called alſo bark of incenſe, and ſometimes Jews' incenſe, becauſe the Jews make frequent uſe thereof in their perfume: this is the *cortex eleutheriæ*.

Manna of incenſe is the flour, or farina of incenſe, occaſioned by the friction of the grains againſt each other in the ſacks wherein they carry it.

There is alſo a ſort of incenſe, which is a preparation of it, burnt like reſin to make lamp-black.

Frankincenſe was formerly burnt in the temples of all religions, to do honour to the divinities that were there adored. Many of the primitive Chriſtians were put to death, becauſe they would not offer incenſe to idols.

In the Romiſh church they ſtill retain the uſe of incenſe in ſome of their ceremonies; always at high-maſs, and at the elevation of the hoſt at veſpers; and at ſolemn funerals, beſtowing it on ſuch perſons as they would honour, as on prelates, &c. and ſometimes alſo on the people.

FRANKLAND'S ISLANDS, in *Geography*, a cluſter of ſmall iſlands on the N.E. coaſt of New Holland, in the South Pacific ocean, about two leagues diſtant from the main land. S. lat. 17° 12'. E. long. 146°.

FRANKLANDIA, in *Botany*, ſo named by Mr. Robert Brown, in his valuable paper on the natural order of *Proteaceæ*, in honour of the preſent ſir Thomas Frankland, bart. F.R.S. and F.L.S., an excellent Engliſh botaniſt, whoſe obſervations, illuſtrated by microſcopic drawings of his own, relating to ſubmarine plants, it is hoped may one day be communicated by himſelf to the public. This genus is happily choſen for the purpoſe, on account of the fucus-like appearance of the leaves.—Brown Tranſ. of Linn. Soc. v. 10. 157. Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*.

Gen. Ch. *Cal.* none, except the corolla be taken for ſuch. *Cor.* of one petal, ſalver-ſhaped, inferior; tube permanent, at length indurated; limb in four deep ſegments, ſpreading, flat, equal, deciduous. Nectary four glands at the baſe of the germen, united into a tube. *Stam.* Filaments four, adhering through their whole length to the tube of the corolla; anthers oblong, included in the tube; pollen ſpherical. *Piſt.* Germen ſuperior, ſtalked; ſtyle ſimple, the length of the tube; ſtigma . . . *Peric.* Nut ſpindle-ſhaped, ſtalked, dilated at the top, and crowned with longiſh down. Cotyledons very ſhort.

Eſſ. Ch. Corolla ſalver-ſhaped; limb in four deep, flat, deciduous ſegments; tube permanent. Anthers included, adhering to the tube. Nectariferous glands united into a cylinder. Nut ſpindle-ſhaped, ſtalked, crowned with long down.

1. F. *fucifolia*. Native of Lewins' land, on the ſouth coaſt of New Holland, in moiſt heaths. *Mr. Brown*. A ſmooth *ſhrub*. Leaves alternate, thread-ſhaped, dichotomous. *Spikes* axillary, ſimple. *Flowers* alternate, of a dull yellow, each accompanied by one *bractea*.

FRANKLIN, BENJAMIN, in *Biography*, was born at Boſton, in New England, in 1706; but he ſprung from a Northamptonſhire family, who had, for many generations, poſſeſſed ſome freehold property at Eaton in that county. It was on account of the perſecutions carried on in the reign of Charles II. againſt the Nonconformiſts, that the father of Benjamin left England for America, where he carried on the trade of a tallow chandler. In that occupation the ſubject of this article was employed in early life; but it was ill adapted to his diſpoſition, and he felt unwilling to continue pulling cottons, filling moulds, and other employment to which his youth was equal, and was anxious to embark in a ſea-faring life. This was oppoſed by his father, who took every care to inſpire in his ſon the principles of morality; and in his ſcanty library Benjamin found books which he read with avidity; but Defoe's "Eſſay on Projects" was the work which gave him moſt delight, and which left on his mind impreſſions that influenced the principal events of his life. His inclination for books determined his father to place him as apprentice to an elder brother, a printer at Boſton. He was accordingly bound to him in the year 1717, when he was ſcarcely twelve years of age. He ſoon became a proficient in the mechanical part of the buſineſs, and ſeized every opportunity for reading books that he could borrow from his acquaintance; in which amuſement he ſpent the greater part of his nights. He ſoon began to indulge himſelf in writing ballads and other poetical pieces; but it is ſaid his father ſpeedily ſatisfied him that this was not the ſpecies of compoſition in which he could excel, and his next efforts were directed to proſe compoſition, in which his ſucceſs is well known and duly appreciated. With a paſſion for reading and writing he imbibed a kindred one for diſputation, and adopting the Socratic method, he became dextrous in confuting and confounding an antagoniſt by a ſeries of queſtions. This courſe gave him a ſceptical turn with regard to religion, and while he was young he took every opportunity of propagating his tenets, and with as much zeal as is ſhewn by a new convert to any other doctrine. He was, however, ſoon convinced, by the effect produced on ſome of his companions, that it was extremely dangerous to looſen the ties of religion without the probability of ſubſtituting other principles equally efficacious. The doubts which ſubſiſted in his own mind he was never able to remove; but he was not deficient in fortifying himſelf with ſuch moral principles, as directed him to the moſt valuable ends by honourable means. He, by habits of ſelf-denial, early formed in his mind, obtained a complete dominion over his appetites, ſo that at the age of ſixteen he readily diſcarded animal food from the conviction produced

in

in his mind by perusing a work on the subject. He now offered his brother to maintain himself for half the sum paid for his board, and even with this he was able to make savings to purchase what books he wanted. In his brother he found a harsh master, and Benjamin felt indignant at the treatment which he experienced from him in the way of business. The brother had set up a newspaper, in which the apprentice contrived to insert some papers and essays anonymously, that were read and highly commended by people of the best judgment and taste in the town. The young man began now to feel his importance, which was still more impressed on him by having the paper published in his own name, that of his brother, for some political offence, having been interdicted by the state. In consequence of this his indentures were cancelled, and he went to New York, and from thence to Philadelphia. Here he contracted an acquaintance with some young men of a literary turn, in whose society he spent his evenings and improved his taste. At Philadelphia he obtained the notice of sir William Keith, the governor, who urged him to set up for himself, at the same time promising him support and protection. Franklin attempted to gain pecuniary aid from his parents, but was disappointed; the governor then persuaded him to make a voyage to England to furnish himself with all necessaries for a new printing-office. He embraced the proposal, and accompanied by his friend Ralph he sailed for England in 1725. Before his departure, he exchanged promises of fidelity with Miss Read of Philadelphia, with whose father he had lodged. Upon his arrival in London, Mr. Franklin found that governor Keith, upon whose letters of credit and recommendation he had relied, had entirely deceived him. He was now obliged to work as a journeyman printer, and obtained employment in an office in Bartholomew-close. His friend did not so readily find the means of subsistence, and was a constant drain upon the earnings of Franklin. In this great city the morals of the young travellers were not much improved; Ralph forgot, or acted as if he had forgotten, that he had a wife and child across the Atlantic; and Franklin was as little attentive to the promises and engagements he was under to Miss Read. About this period he published "A Dissertation on Liberty and Necessity, Pleasure and Pain," dedicated to Ralph, and intended as an answer to Woolaston's "Religion of Nature." This piece gained for him some degree of reputation, and introduced him to the acquaintance of Dr. Mandeville, author of the "Fable of the Bees," and some other literary characters. Franklin was always temperate and industrious, and his habits in these respects were eventually the means of securing his morals, as well as of raising his fortune. In the interesting account which he has left of his own life, Mr. Franklin has given a narrative of the method which he took in reforming the sottish habits of his fellow workmen in the second printing-office in which he was engaged in London, and which was situated in the neighbourhood of Lincoln's-inn-fields. He tried to persuade them that there was more real sustenance in a penny roll than in a pint of porter; at first the plan of economy which he proposed was treated with contempt or ridicule, but in the end he was able to induce several of them to substitute a warm and nourishing breakfast in the place of stimulating liquors. In 1726 he returned to Philadelphia, where he first engaged himself as clerk in a mercantile house; and in the course of a year he became the superintendant of Keimer's printing-office, where he acquired so much esteem, and so far improved his connections, that he resolved to embark in business for himself. He entered into partnership with a fellow workman named Meredith, whose friends were enabled to furnish a supply of money sufficient for the concern, which was no doubt very small; for Franklin has recorded the high degree of pleasure which he experienced from a payment of five shillings only, the first fruits of their earnings. "The recollection," says this noble spirited man, "of what I felt on this occasion, has rendered me more disposed, than perhaps I might otherwise have been, to encourage young beginners in trade." His habitual industry and undeviating punctuality obtained him the notice and business of the principal people in the place. He instituted a club under the name of "the Junto," for the purpose of the discussion of political and philosophical questions, which proved an excellent school for the mutual improvement of its several members. The test proposed to every candidate before his admission was this; "Do you sincerely declare that you love mankind in general, of what profession or religion soever? Do you think any person ought to be harmed in his body, name, or goods, for mere speculative opinions, or his external way of worship? Do you love truth for truth's sake; and will you endeavour impartially to find and receive it yourself, and communicate it to others." Mr. Franklin and his partner ventured to set up a new public paper, which his own efforts as writer and printer caused to succeed, and they obtained likewise the printing of the votes and laws of the assembly. In process of time, Meredith withdrew from the partnership, and Franklin met with friends who enabled him to undertake the whole concern in his own hands, and add to it the business of a stationer. A discussion concerning a new emission of paper-money taking place, he wrote an anonymous pamphlet in favour of the measure, which was received with applause, and which contributed to the success of the measure, and to the prosperity of the writer. In 1730 he married the lady to whom he had pledged his vows before he embarked for England, although, from his neglect of her, she had been before married to a man then dead. The establishment of a public library was one of the useful projects of Franklin, which he brought to effect in 1731, and he had the satisfaction of seeing it advance to that flourishing state which it has long maintained. In 1732 he began to publish "Poor Richard's almanac," a work which became remarkable by the number of excellent prudential maxims occasionally inserted in it, calculated, by their conciseness, to be readily and indelibly impressed on the memory. They have been since collected into a single piece, entitled "The way to wealth," which has been published in a variety of forms. The political career of Benjamin Franklin began in the year 1736, when he was appointed clerk to the general assembly of Pennsylvania; an office which he held for several years, till he was at length elected a representative. In the following year he obtained the valuable office of post-master to the city of Philadelphia. In 1738 he improved the police of the city, with respect to the dreadful calamity of fire, by forming a society called a fire company, to which was afterwards added an assurance office against losses by fire. In the French war of 1744 he stood forth and proposed a plan of voluntary association for defence, which was shortly joined by 10,000 persons. Franklin was chosen colonel of the Philadelphia regiment, which he did not accept, on account of the pursuits in which he was then engaged. Peter Collinson had sent to the library society of Philadelphia an account of the curious facts relative to electricity, which then absorbed the attention of the European philosophers, together with a tube for experiments, and directions for its use. Franklin, with some of his friends, immediately began to apply to the subject, and in a short time he made many valuable and highly important discoveries, an account of which he published in three pieces, entitled "New experiments and observations in Electricity, made at Philadelphia in America." Although we may generally refer to the articles

ELECTRICAL *Attraction* and *Repulſion*, ELECTRICITY, &c. for full information on this ſubject, yet we cannot forbear giving ſome account of Mr. Franklin's diſcoveries. Having been led to think, that in the excitation of the electric tube the fluid was conveyed from the perſon who rubbed it, to him who touched it, he deſignated the ſtate of the latter, by the expreſſion of being electrified *poſitively* or *plus*, as having received more than his original quantity, while the former was ſaid to be electrified *negatively* or *minus*, as having loſt a part of his natural portion. This led to the diſcovery of the Leyden phial, the theory of which is, that when one ſide of the glaſs is electrified plus, the other ſide is electrified minus; ſo that in charging it, all that is done is to throw the electricity from one ſide, and convey it to the other, while diſcharging it is the reſtoration of the equilibrium. He farther demonſtrated, by deciſive experiments, that the accumulated electricity in the charged ſide of the phial reſided not in the coating, but in the glaſs itſelf; but the moſt brilliant of his diſcoveries was that which proved the identity of the electric fluid and lightning. Their ſimilarity had been ſuſpected by the abbé Nollet, and ſome experiments had begun to be made in France towards the verification of the fact, but Franklin completed the proof of it entirely by his own experiments. In the year 1749 he conceived the idea of explaining the phenomena of thunder-guſts, and of the aurora borealis upon electrical principles; he pointed out many particulars, in which lightning and electricity agreed, and he adduced many facts and reaſonings, from facts, in ſupport of his poſitions. In the ſame year he thought of aſcertaining the truth of his doctrine by drawing down the forked lightning, by means of ſharp-pointed iron rods raiſed into the region of the clouds. Admitting the identity of electricity, and knowing the power of points in conducting away ſilently the electric fluid, he ſuggeſted the idea of ſecuring houſes, ſhips, &c. from the damages to which they were liable from lightning, by erecting pointed iron rods, which ſhould riſe ſome feet above the moſt elevated part, and deſcend ſome feet into the ground, or the water. The effect of theſe, he concluded, would be either to prevent a ſtroke by repelling the cloud beyond the ſtriking diſtance, or by drawing off the electrical fluid which it contained; or, at leaſt, conduct the ſtroke to the earth, without any injury to the building. It was not till the ſummer 1752, that Mr. Franklin was enabled to complete his grand experiment. The plan which he propoſed was, to erect on ſome high tower, or other elevated place, a ſort of hut, from which ſhould riſe a pointed iron rod, inſulated by being fixed in a cake of reſin. Electrified clouds paſſing over this would, he conceived, impart to it a portion of their electricity, which might be rendered evident to the ſenſes by ſparks being emitted, when the knuckle or other conductor was preſented to it. While he was waiting for the erection of a ſpire, it occurred to him, that he might have more ready acceſs to the region of clouds by means of a common kite; he accordingly prepared one for the purpoſe, affixing to the upright ſtick an iron point. The ſtring was, as uſual, of hemp, except the lower end, which was ſilk, and where the hempen part terminated, a key was faſtened. With this ſimple apparatus, on the appearance of a thunder ſtorm approaching, he went into the fields, accompanied by his ſon, to whom alone he communicated his intentions, dreading, probably, the ridicule which frequently awaits unſucceſsful attempts in experimental philoſophy. For ſome time no ſign of electricity appeared; he was beginning to deſpair of ſucceſs, when he ſuddenly obſerved the looſe fibres of the ſtring to ſtart forward in an erect poſition. He now preſented his knuckle to the key, and received a ſtrong ſpark. How exquiſite muſt his ſenſations have been at this moment? On this experiment depended the fate of his theory; repeated ſparks were drawn from the key, a phial was charged, a ſhock given, and all the experiments made, which are uſually performed with electricity. He immediately fixed an inſulated iron rod upon his houſe, which drew down the lightning, and gave him an opportunity of examining whether it were poſitive or negative, and hence he applied his diſcovery to the ſecuring of buildings from the effects of lightning. (See CONDUCTOR.) Previouſly to his experiments in electricity he applied his mechanical and philoſophical knowledge to the conſtruction of *fire-places* (which ſee), combining the qualities of an open grate with that of a ſtove. As a politician he had been elected a repreſentative of the city of Philadelphia to the general aſſembly of the province. His principles in favour of equality of rights led him always to take the popular ſide, and he quickly obtained ſuch an influence that he was regarded as the head of the party. The ability and punctuality which he had diſplayed in his office of poſt-maſter, cauſed him, in 1753, to be raiſed to the important employ of deputy poſt-maſter for the Britiſh colonies. He was uſeful in various other capacities to the government, and when in 1757 the militia was to be diſbanded by orders from England, he ſailed for London, in the capacity of agent for Pennſylvania, the aſſembly of which was involved in warm diſputes with the proprietary intereſt. After much diſcuſſion before the privy council, it was agreed, that the proprietary lands ſhould take their ſhare in a tax for the public ſervice, provided that Franklin would engage that the aſſeſſment ſhould be fairly proportioned. The meaſure was accordingly carried into effect, and he remained at the Britiſh court as agent for his province, and his reputation cauſed him alſo to be entruſted with the like commiſſion from Maſſachuſets, Maryland, and Georgia. The moleſtation received by the Britiſh colonies from the French in Canada induced him to write a pamphlet, pointing out the advantages of a conqueſt of that province by the Engliſh; and the ſubſequent expedition againſt it, and its retention under the Britiſh government, at the peace, were, it is believed, much influenced by the force of his arguments on the ſubject. About this period his talents, as a philoſopher, were duly appreciated in various parts of Europe. He was admitted a fellow of the Royal Society of London, and the degree of doctor of laws was conferred upon him at St. Andrew's, Edinburgh, and Oxford.

He returned to America in 1762, where he received the thanks of the aſſembly for his ſervices, and a remuneration for his labours undertaken and accompliſhed on their behalf. He reſumed his ſeat in that body, to which he had been annually elected during his abſence, and continued to diſtinguiſh himſelf as a friend to the cauſe of the people. The active part which he took againſt the proprietary intereſt occaſioned the loſs of his election in 1764, but he was immediately re-appointed agent for the province, and embarked again for England. It was at this period that the ſtamp-act excited ſuch violent commotions in America; and Dr. Franklin, almoſt immediately after his return to London, was called to the bar of the houſe of commons, to give evidence reſpecting the diſpoſitions of the people to ſubmit to it. His repreſentations had a conſiderable effect in producing the repeal of that obnoxious meaſure. In the years 1766 and 1767 he paid viſits to Holland, Germany and France, where he met with a very diſtinguiſhed reception. In 1773 he attracted the public attention by a letter on the duel between Mr. Whately and Mr. Temple concerning the publication of governor Hutchinſon's letters, avowing himſelf to be the perſon who obtained theſe letters and tranſmitted

mitted them to the legiſlature in America, which he had done from a ſenſe of duty as the agent of the colony. This occaſioned a violent clamour to be raiſed againſt him, and upon his attending before the privy council in the following January, to preſent a petition from the colony for the diſmiſſion of Mr. Hutchinſon, a moſt virulent invective was pronounced againſt him by Mr. Wedderburne, filled with all the abuſe which too frequently characterizes the eloquence of the bar. In a very ſhort time after this he was removed from his office of poſt-maſter-general for America. Finding all his efforts to reſtore harmony between Great Britain and the colonies uſeleſs, he returned to America in 1775, juſt after the commencement of hoſtilities, and being named one of the delegates of the continental congreſs, he had the principal ſhare in bringing about the revolution and declaration of independence on the part of America. In 1776, he was deputed by congreſs to Canada, to negociate with the people of that country, and to perſuade them to throw off the Britiſh yoke; but the inhabitants of Canada had been ſo much diſguſted with the zeal of the people of New England, who had burnt ſome of their chapels, that they refuſed to liſten to the propoſals made to them by Dr. Franklin. On the arrival of lord Howe in America in 1776, he entered upon a correſpondence with him on the ſubject of reconciliation. He was afterwards appointed, with two others, to wait upon the Engliſh commiſſioners, and learn the extent of their powers, but as theſe only went to the granting pardon upon ſubmiſſion, he joined his colleagues in conſidering them as inſufficient. Dr. Franklin was decidedly in favour of a declaration of independence, and was appointed preſident of the convention aſſembled for the purpoſe of eſtabliſhing a new government for the ſtate of Pennſylvania. When it was determined by congreſs to open a public negociation with France, Dr. Franklin was fixed upon to go to that country, and he brought about the treaty of alliance offenſive and defenſive, which produced an immediate war between England and France. Dr. Franklin was one of the commiſſioners who, on the part of the United States, ſigned the proviſional articles of peace in 1782, and the definitive treaty in the following year. Before he left Europe, he concluded a treaty with Sweden and Pruſſia. By the latter he obtained ſeveral moſt liberal and humane ſtipulations in favour of the freedom of commerce, and the ſecurity of private property during war, in conformity to thoſe principles which he had ever maintained on theſe ſubjects. Having ſeen the accompliſhment of his wiſhes in the independence of his country, he requeſted to be recalled, and after repeated ſolicitations Mr. Jefferſon was appointed in his ſtead. On the arrival of his ſucceſſor he repaired to Havre de Grace, and croſſing the Engliſh channel, landed at Newport in the Iſle of Wight, from whence, after a favourable paſſage, he arrived ſafe at Philadelphia, in Sept. 1785. Here he was received amidſt the acclamations of a vaſt and almoſt innumerable multitude, who had flocked from all parts to ſee him, and who conducted him in triumph to his own houſe, where in a few days he was viſited by the members of congreſs, and the principal inhabitants of Philadelphia. He was afterwards twice choſen preſident of the aſſembly of Philadelphia; but in the year 1788 the increaſing infirmities of his age obliged him to aſk and obtain permiſſion to retire and ſpend the remainder of his life in tranquillity, and on the ſeventeenth of April 1790 he cloſed, in ſerenity and reſignation, his active and uſeful life, having attained the great age of eighty-four years and three months. He left behind him one ſon, a zealous loyaliſt, and a daughter married to a merchant in Philadelphia. Dr. Franklin was author of many tracts on electricity, and other branches of natural philoſophy, as well as on political and miſcellaneous ſubjects. Many of his papers are inſerted in the Philoſophical Tranſactions of London; and his eſſays have been frequently reprinted in this country as well as in America, and have, in common with his other works, been tranſlated into ſeveral modern languages. Franklin's Life by himſelf. Prieſtley's Hiſt. of Electricity.

FRANKLIN, in *Geography*, a county of America, being the north-weſternmoſt in Vermont, bounded N. by Lower Canada, and W. by lake Champlain. It contains 20 townſhips, and 8781 inhabitants.—Alſo, a county in Pennſylvania, bounded N. by Mifflin, N.E. by Cumberland, E. by York, S. by Waſhington county in Maryland, W. by Bedford county, and N.W. by Hunterdon. It is computed to contain 800 ſquare miles, equal to 512,000 acres. It comprehends the middle part of the beautiful and rich valley of Conegocheague, watered by the creek of its name, which falls into Potowmack at Williams port in Maryland. Iron ore is found in this county ſufficient to furniſh work for a furnace and forge. The county is divided into 14 townſhips, containing 19,638 inhabitants.—Alſo, a poſt-town in Venango county, Pennſylvania; 322 miles from Waſhington.—Alſo, a poſt-town of Ohio; 560 miles from Waſhington.—Alſo, a poſt-town of Pendleton county, in Virginia; 191 miles from Waſhington.—Alſo, a poſt-town in Williamſon county, Teneſſee; 575 miles from Waſhington.—Alſo, a town in Ducheſs county, New York, on the Connecticut line, 10 miles N.W. of Danbury; containing 1546 inhabitants.—Alſo, a county of Kentucky, bounded N. by Scott county, N.W. and W. by Shelby, S.E. by Fayette, and S. by Woodford. It contains 4450 inhabitants, of whom 1109 are ſlaves. The chief town is Frankfort.—Alſo, a county in Halifax diſtrict, North Carolina, containing 8473 inhabitants, of whom 3667 are ſlaves. It is bounded N. by Greenville, S. by Johnſton, N.E. by Warren, S.W. by Wake, and W. by Orange county. The chief town is Lewiſburg.—Alſo, a county in Virginia, bounded N. by Bedford, N.W. by Botecourt, W. by Montgomery, S.W. by Henry, S. by Patrick, and E. by Campbell county. It is about 40 miles long, and 25 broad, and contains 7728 free inhabitants, and 1574 ſlaves. It is generally hilly, and is traverſed on the N.W. by a range of the Alleghany mountains.—Alſo, a county in Georgia, ſituated in the upper diſtrict, bounded E. and N.E. by Tugulo river, which ſeparates it from the ſtate of South Carolina; W. and N.W. by the country of the Cherokees; S. by the head branches of Broad river; and S.E. by Elbert county. It contains 6859 inhabitants, of whom 959 are ſlaves. The court-houſe is 77 miles from Waſhington.—Alſo, a townſhip in Norfolk county, Maſſachuſets, incorporated in 1778, and containing 17,000 acres of land, and 1285 inhabitants. It is bounded N. by Charles river, which ſeparates it from Medway, and lies 30 miles S. of Boſton.—Alſo, a ſmall iſle at the mouth of St. George's river, in Lincoln county, and ſtate of Maine; four leagues ſouthward of Thomaſton.—Alſo, a poſt-town in Delaware county, S.W. from, and bordering on, Harpersfield, and its W. line runs along the ſouth-eaſtern bank of the Suſquehannah river. This town was divided by an act of the legiſlature in 1747. It contains 1390 inhabitants.—Alſo, a townſhip in Weſtmoreland county, Pennſylvania.—Alſo, three others in the ſame ſtate, *viz.* in York county, Fayette county, and Waſhington county.—Alſo, a townſhip, being the northernmoſt in New London county, Connecticut, 6 miles N.W. of Norwich; containing 1210 inhabitants, who are chiefly wealthy farmers.—Alſo, a county in the ſtate of Ohio.

FRANKLIN *College*. See LANCASTER.

FRANKLIN, *Fort*, was erected in 1787 in Alleghany county, Pennſylvania, near the poſt called Venango, in order to defend the frontiers of Pennſylvania from the depredations of the neighbouring Indians. It is ſeated on the S.W. bank of Alleghany river, oppoſite to the mouth of the French creek; 53 miles S.S.E. of Preſque iſle, and 63 northward of Pittſburg. N. lat. 41° 1′ 40″. W. long. 79° 41′.

FRANKLINIA, in *Botany*, named by Marſhall in honour of the celebrated Dr. Benjamin Franklin. See GORDONIA.

FRANKS, in *Geography*, a town of Huntingdon county, Pennſylvania, on the Frankſtown branch of Juniatta river, 20 miles W. of Huntingdon, and containing 743 inhabitants.

FRANKS, *Francs*, *Frankis*, or *Franquis*, a name which the Turks, Arabs, Greeks, &c. give to all the people of the weſtern parts of Europe.

The appellation is commonly ſuppoſed to have had its riſe in Aſia, at the time of the croiſades, when the French made the moſt conſiderable figure among the croiſees; from which time the Turks, Saracens, Greeks, Abyſſinians, &c. uſed it as a common term for all the Chriſtians of Europe; and called Europe itſelf Frankiſtan.

The Arabs and Mahometans, ſays M. d'Herbelot, apply the term Franks, not only to the French, (to whom the name originally belonged,) but alſo to the Latins and Europeans in general.

But F. Goar, in his notes on Condinus, cap. 5. n. 43, furniſhes another origin of the appellation Franks, of greater antiquity than the former. He obſerves, that the Greeks at firſt confined the name to the Franci, *i. e.* the German nations, who had ſettled themſelves in France or Gaul, but afterwards they gave the ſame name to the Apulians and Calabrians, after they had been conquered by the Normans; and at length the name was farther extended to all the Latins.

In this ſenſe is the word uſed by divers Greek writers, as Comnenius, &c. who, to diſtinguiſh the French, call them the weſtern Franks.

Du-Cange adds, that about the time of Charlemagne, they diſtinguiſhed eaſtern France, weſtern France, Latin, or Roman France, and German France, which was the ancient France, afterwards called Franconia.

The origin and confederacy of the Franks, whoſe poſterity, in proceſs of time, conquered Gaul, and impoſed their own name on the country (ſee FRANCE), have been the ſubject of learned inveſtigation, and of various conjectures and opinions. It has been ſuppoſed that Pannonia, that Gaul itſelf, and that the northern parts of Germany gave birth to this celebrated colony of warriors. At length (ſays Gibbon, Hiſt. vol. i.) the moſt rational critics, rejecting the fictitious emigrations of ideal conquerors, have acquieſced in a ſentiment, whoſe ſimplicity perſuades us of its truth. They ſuppoſe, that about the year 240, probably under the reign of Gordian III. a new confederacy was formed under the name of Franks, by the old inhabitants of the Lower Rhine, and the Weſer. The diſtrict which they originally inhabited was bounded on the N. by the ocean, on the W. by the ocean and the Rhine, on the S. by the Main, and on the E. by the Weſer: ſo that according to this deſcription they poſſeſſed the preſent provinces of Weſtphalia, Heſſe, and ſome adjacent ſtates. The Chauci, Cheruſci, Catti, and other tribes of inferior power and authority, animated by the love of liberty, counted the enjoyment of it their richeſt treaſure; and of courſe the word that expreſſed this enjoyment was the moſt pleaſing to their ears. Accordingly they deſerved, they aſſumed, they maintained the honourable epithet of "Franks," or "freemen," which concealed, though it did not extinguiſh, the peculiar names of the ſeveral ſtates of the confederacy. Tacit conſent, and mutual advantage, dictated the firſt laws of the union; and it was gradually cemented by habit and experience. This league of the Franks in ſome reſpects reſembles that of the Helvetic body; in which every canton, retaining its independent ſovereignty, conſults with its brethren in the common cauſe, without acknowledging the authority of any ſupreme head, or repreſentative aſſembly. But the principle of the two confederacies was extremely different. A peace of 200 years has rewarded the wiſe and honeſt policy of the Swiſs; whereas the inconſtant ſpirit, the thirſt of rapine, and a diſregard to the moſt ſolemn treaties, diſgraced the character of the Franks. The Rhine, though dignified with the title of the ſafeguard of the provinces, proved to be an imperfect barrier againſt the daring ſpirit of enterpriſe with which the Franks were actuated; their rapid devaſtations ſtretched from the river to the foot of the Pyrenées; nor were they ſtopped by theſe mountains. Spain, which had never dreaded, was unable to reſiſt, the inroads of the Germans. When the exhauſted country no longer ſupplied a variety of plunder, the Franks ſeized on ſome veſſels in the ports of Spain, and tranſported themſelves into Mauritania. Their irruptions into Gaul were repulſed by Aurelian, when he was only tribune of the ſixth legion, when 700 of them were killed, and 300 made priſoners and ſold for ſlaves; and again, in the fourth year of Valerian they made another excurſion, and were defeated by Gallienus; and after the captivity of Valerian, they again invaded Gaul, and having ravaged the moſt wealthy provinces, made an irruption into Italy. At the death of Aurelian, the Franks, and ſome other German tribes, croſſed the Rhine and entered Gaul; and having reduced a great number of the chief cities, in two years conſidered themſelves as maſters of the country; but under the reign of Probus, about A. D. 277, the Franks and other German tribes were driven back into their moraſſes; from which deſcriptive circumſtances we may infer, that the confederacy known by the appellation of "free," already occupied the flat maritime country, interſected, and almoſt overflown by the ſtagnating waters of the Rhine, and that ſeveral tribes of the Friſians and Batavians had acceded to their alliance. The emperor, not ſatisfied with driving them out of Gaul, purſued them acroſs the Rhine, laid waſte their territories, and built ſome forts in their country; but upon their ſuing for peace, they obtained it on condition of their ſupplying the Romans yearly with a quantity of corn, and finding 16,000 men to ſerve in the Roman army. Some of theſe Franks were eſtabliſhed by Probus, on the ſea-coaſt of Pontus, with a view of ſtrengthening the frontiers againſt the inroads of the Alani; but as a fleet ſtationed in one of the harbours of the Euxine fell into their hands, they reſolved, through unknown ſeas, to explore their way from the mouth of the Phaſis to that of the Rhine. They eaſily eſcaped through the Boſphorus and the Helleſpont, and cruizing along the Mediterranean, indulged their appetite for revenge and plunder, by frequent deſcents on the unſuſpecting ſhores of Aſia, Greece, and Africa. The opulent city of Syracuſe was ſacked by a handful of barbarians, who maſſacred the greateſt part of the trembling inhabitants.

From the iſland of Sicily the Franks proceeded to the columns of Hercules, truſted themſelves to the ocean; coaſted round Spain and Gaul, and ſteering their triumphant courſe through the Britiſh channel, at length finiſhed their ſurpriſing voyage, by landing in ſafety on the Batavian

or Friſian ſhores. This event happened about the year 280. Their countrymen, inſtructed by their example to deſpiſe the dangers of the ſea, and animated by the hope of ſimilar ſucceſs, were led to purſue, in the indulgence of their enterpriſing ſpirit, a new road to wealth and glory. When Proculus revolted and aſſumed the title of emperor at Cologne, the Franks at firſt eſpouſed his cauſe, but afterwards abandoned him, and betrayed the uſurper into the emperor's hands. From this period to the fourth year of Diocleſian they continued quiet, till joining ſome Saxon pirates, they plundered the coaſt of Gaul, and carried off an immenſe booty, and an incredible number of captives; but Carauſius having, by the emperor's order, equipped a fleet at Boulogne, and gained ſome advantages over them, they retired for a time to their reſpective countries. In the following year Maximian croſſed the Rhine and deſolated their country; which ſtruck ſuch terror into the minds of the Franks, that two of their kings or chiefs ſubmitted to him, and requeſted to be confirmed by him in their reſpective kingdoms. Maximian granted lands in the vicinity of Treves and Cambray to great numbers of the Franks and Letes, who had ſubmitted themſelves; thoſe territories being almoſt quite deſtitute of inhabitants. A few years after this tranſaction, the Franks reduced Batavia, and that part of Flanders which is watered by the river Eſcaut; but Conſtantius, the father of Conſtantine the Great, marched againſt them and defeated them in battle; and, having obliged them to ſurrender at diſcretion, he tranſplanted them and their families into Gaul, where they were obliged to cultivate the lands which they themſelves had waſted, to pay the uſual tributes and taxes, as ſubjects of the empire, and to ſerve, when wanted, in the Roman armies. From this period, A. D. 293, they continued quiet till the year 306, the firſt year of Conſtantine's reign, when they ſeized the opportunity afforded them by his abſence in Britain to invade Gaul; but the emperor, on his return, purſued them with dreadful havoc acroſs the Rhine, and took many priſoners. During Conſtantine's reign they made ſeveral irruptions into Gaul, which drew upon them very ſevere puniſhment. When Conſtantius, in the blind fury of civil diſcord, about the middle of the fourth century, had abandoned to the barbarians of Germany the countries of Gaul, which ſtill acknowledged the authority of his rival, a numerous ſwarm of Franks and Alemanni were invited to croſs the Rhine by preſents and promiſes, by the hopes of ſpoil, and by a perpetual grant of all the territories which they ſhould be able to ſubdue. Theſe formidable allies the emperor found it difficult to diſmiſs; and, acting the part of undiſciplined robbers, they pillaged 45 flouriſhing cities, and ſeveral towns and villages, and reduced many of them to aſhes. The German barbarians, abhorring the confinement of walls, fixed their independent habitations on the banks of rivers, the Rhine, the Moſelle, and the Meuſe, and ſecured themſelves againſt ſurpriſe by a rude and haſty fortification of large trees, which were felled and thrown acroſs the roads. At this time the Franks occupied the iſland of the Batavians, together with an extenſive diſtrict of Brabant, which was then known by the appellation of Toxandria, a country of woods and moraſſes that extended from the vicinity of Tongres to the conflux of the Vahal and the Rhine, and which may be conſidered as the original ſeat of their Gallic monarchy. After Julian, A. D. 358, had repulſed the Alemanni from the provinces of the Upper Rhine, he turned his arms againſt the Franks, who were ſeated nearer to the ocean on the confines of Gaul and Germany; and who, on account of their number and intrepid valour, had ever been eſteemed the moſt formidable of the barbarians. Although they were ſtrongly actuated by the allurements of rapine, they profeſſed a diſintereſted love of war, which they conſidered as the ſupreme honour and felicity of human nature; and their minds and bodies were ſo completely hardened by perpetual action, that, according to the lively expreſſion of an orator, the ſnows of winter were as pleaſant to them as the flowers of ſpring. In the month of December, A. D. 358, Julian attacked a body of 600 Franks, who had thrown themſelves into two caſtles on the Meuſe. Having, with inflexible conſtancy, in the midſt of that ſevere ſeaſon, ſuſtained a ſiege of 54 days, they were at length exhauſted by hunger, and deſpairing of eſcape, they conſented, for the firſt time, to diſpenſe with the ancient law, which commanded them to conquer or to die. This obſtinate reſiſtance on the part of a ſmall number of Franks, appriſed Julian of the difficulties with which he was likely to encounter in the expedition meditated by him for the enſuing ſpring, againſt the whole body of the nation. His diligence and activity correſponded to the occaſion; and without allowing the Franks to deliberate or to unite, he ſpread his legions from Cologne to the ocean, and ſoon conſtrained the ſuppliant tribes to implore the clemency, and to obey the commands, of their conqueror. A treaty was ratified by ſolemn oaths; and perpetual inſpectors were appointed to reſide among the Franks, with the authority of enforcing the ſtrict obſervance of the conditions. Towards the commencement of the 5th century, the Franks diſtinguiſhed their zeal and courage in the defence of the Roman empire: when the limits of Gaul and Germany were ſhaken by the northern emigration, the Franks bravely encountered the ſingle force of the Vandals; and of theſe 20,000, with their king Godigiſclus, were ſlain on the field of battle. By this attachment to the Roman government, on the part of the Franks, as well as by the neutrality of the Alemanni, the peace of Germany was ſecured. In the laſt years of the emperor Honorius, the Franks, as well as the Goths and Burgundians, obtained a permanent ſeat and dominion in the provinces of Gaul; Treves, the capital of Gaul, was pillaged by their lawleſs bands; and the humble colony, which they ſo long maintained in the diſtrict of Toxandria in Brabant inſenſibly multiplied along the banks of the Meuſe and Scheldt, till their independent power filled the whole extent of the Second, or Lower Germany. It was about this time, A. D. 420, that Pharamond, ſuppoſed by ſome to be the ſon of Sunno, but more generally the ſon of Marcamir, the brother of Sunno, is ſaid to have reigned over the Franks: but the foundation of the French monarchy by Pharamond, the conqueſts, the laws, and even the exiſtence of that hero, have been juſtly arraigned, ſays Gibbon, by the impartial ſeverity of modern criticiſm. Pharamond, if we admit the exiſtence of ſuch a ſovereign among the Franks, was ſucceeded by his ſon Clodion in the year 428, the fourth of the reign of Valentinian III. From the report of his ſpies, the king of the Franks was informed that the defenceleſs ſtate of the ſecond Belgic muſt yield, on the ſlighteſt attack, to the valour of his ſubjects. He boldly penetrated the thickets and moraſſes of the Carbonarian foreſt, which is part of the great foreſt of the Ardennes, that lay between the Eſcaut or Scheldt, and the Meuſe; occupied Tournay and Cambray, the only cities which exiſted in the 5th century, and extended his conqueſts as far as the river Somme, over a deſolate country, whoſe cultivation and populouſneſs are the effects of more recent induſtry. While Clodion lay encamped in the plains of Artois, and employed himſelf in celebrating, with oſtentatious ſecurity, the marriage of one of his chiefs, perhaps of his ſon, the nuptial feaſt was interrupted by the unexpected arrival and aſſault of Ætius. The Franks were oppreſſed before they could recover their

arms or their ranks; and their unavailing valour was fatal only to themſelves. The king of the Franks, however, ſoon regained his ſtrength and reputation, and ſtill maintained the poſſeſſion of his Gallic kingdom from the Rhine to the Somme. Under his reign, and moſt probably from the enterpriſing ſpirit of his ſubjects, the three capitals, Mentz, Treves, and Cologne, experienced the effects of hoſtile cruelty and avarice. The diſtreſs of Cologne was prolonged by the perpetual dominion of the ſame barbarians who evacuated the ruins of Treves; and Treves, which in the ſpace of forty years had been four times beſieged and pillaged, was diſpoſed to loſe the memory of her afflictions in the vain amuſements of the circus.

The death of Clodion, after a reign of twenty years, expoſed his kingdom to the diſcord and ambition of his two ſons. Meroveus, the younger, was perſuaded to implore the protection of Rome; he was received at the imperial court as the ally of Valentinian, and the adopted ſon of the patrician Ætius; and diſmiſſed to his native country with ſplendid gifts, and the ſtrongeſt aſſurances of friendſhip and ſupport. During his abſence, his elder brother had ſolicited, with equal ardour, the formidable aid of Attila; and the king of the Huns embraced an alliance, which facilitated the paſſage of the Rhine, and juſtified, by a ſpecious and honourable pretence, the invaſion of Gaul. Meroveus died, as ſome ſay, in 456, but, according to others, in 458; after having lived and reigned, loved and honoured by his people as a common father; and from him the Franks in general were called Merovingians. In a genealogical table of the French kings, prefixed to a MS. life of Charles the Great, lodged in the royal library at Bruſſels, he is made the ſtock or head of the firſt race. Meroveus was ſucceeded by his ſon Childeric. As ſoon as he aſcended the throne he began to think of enlarging his dominions; and he is ſaid to have extended his conqueſts as far as the Loire, and to have reduced the city of Paris, after a ſiege of ten years. He likewiſe made himſelf maſter of Angers and alſo of Orleans. He died at Tornacum, now Tournay. In early life he was addicted to very licentious practices, and the Franks, incenſed by his conduct, puniſhed him with exile, and elected Œgidius, a Roman general, for their king. However, the nation, at the end of four years, repented of the injury which they had offered to the Merovingian family, and patiently acquieſced in the reſtoration of the exiled prince. While Childeric lived an exile in Germany, he was hoſpitably entertained by the queen as well as by the king of the Thuringians. After his reſtoration, Baſina eſcaped from her huſband's bed to the arms of her lover. Childeric is ſaid to have married her; but however that be, the offſpring of their union was Clovis; who, when he was no more than fifteen years of age, ſucceeded by his father's death, A. D. 482, to the command of the Salian tribe. The narrow limits of his kingdom were confined to the iſland of the Batavians, with the ancient dioceſes of Tournay and Arras; and at the baptiſm of Clovis, the number of his warriors could not exceed five thouſand. The kindred tribes of the Franks, who had ſeated themſelves along the Belgic rivers, the Scheldt, the Meuſe, the Moſelle, and the Rhine, were governed by their independent kings, of the Merovingian race; the equals, the allies, and ſometimes the enemies, of the Salic prince. But the Germans who obeyed, in peace, the hereditary juriſdiction of their chiefs, were free to follow the ſtandard of a popular and victorious general; and the ſuperior merit of Clovis attracted the reſpect and allegiance of the national confederacy. (See Clovis.) In the year 536, twenty-five years after the death of Clovis, the French monarchy in Gaul was finally eſtabliſhed. The Oſtrogoths of Italy, unable to defend their diſtant acquiſitions, had reſigned to the Franks the cities of Arles and Marſeilles; this tranſaction was confirmed by the imperial authority, and Juſtinian, generouſly yielding to the Franks the ſovereignty of the countries beyond the Alps, which they already poſſeſſed, abſolved the provincials from their allegiance; and eſtabliſhed on a more lawful, though not more ſolid, foundation, the throne of the Merovingians. (See France.) The Franks, or French, are the only people of Europe who can deduce a perpetual ſucceſſion from the conquerors of the weſtern empire. But their conqueſt of Gaul was followed by ten centuries of anarchy and ignorance.

The Franks were tall of ſtature, with light hair and blue eyes; and as to their military character, we may obſerve, that their love of freedom and of arms was felt, with conſcious pride, by the Franks themſelves, and it was obſerved by the Greeks with ſome degree of amazement and terror. "The Franks," ſays the emperor Conſtantine, "are bold and valiant to the verge of temerity; and their dauntleſs ſpirit is ſupported by the contempt of danger and of death. In the field, and in cloſe onſet, they preſs to the front, and ruſh headlong againſt the enemy, without deigning to compute either his numbers or their own. Their ranks are formed by the firm connections of conſanguinity and friendſhip; and their martial deeds are prompted by the deſire of ſaving or revenging their deareſt companions. In their eyes, a retreat is a ſhameful flight: and flight is indelible infamy." Gibbon's Hiſt. of the Decline, &c. of the Roman Empire. The Franks, as we have already remarked, inhabited foreſts and marſhes, where their women reſided; their cabins were of wood, conſtructed without art, and formed into ſcattered villages without order. Theſe ſavages united together under the command of a prince, and went with him to war, without acknowledging his dominion over them in time of peace: their princes were rather the chiefs of the ſoldiers than the kings of the people: they paid him no tribute, divided the ſpoils, and made him preſents. Such were the conquerors of Gaul, and the founders of the French monarchy. (See France.) In proceſs of time they became Chriſtians, and inſenſibly loſt their ancient manners. Their democracy was aboliſhed, and a military ariſtocracy ſucceeded.

FRANKSTADT, in *Geography*, a town of Moravia, in the circle of Prerau; four miles S. of Freyburg. N. lat. 49° 29'. E. long. 18° 17'.

FRANKWALD, or Puskowitz, a town of Sileſia, in the principality of Oels; four miles N.W. of Feſtenberg.

FRANQUEMONT, a town of Switzerland, in the canton of Porentru, ſeated on the Dou; 16 miles N. of Neufchatel.

FRANSCHE Hoeck, or *French Corner*, a ſubordinate diſtrict of the valley of Drakenſtein in ſouthern Africa, near the Cape of Good Hope, ſituated in the S.E. angle of the valley among the mountains; deriving its name from the French refugees who ſettled here, when they fled to this country after the revocation of the edict of Nantes. To theſe people the colony is indebted for the introduction of the vine. The eſtates here are commonly freehold property, and produce little elſe than wine and fruits.

FRANSERIA, in *Botany*, named by Cavanilles in honour of Dr. Antony Franſero, a phyſician of Madrid, rather, as it ſeems, from motives of perſonal regard, than from any botanical merits in his friend. Cav. Ic. 2. 78. Willd. Sp. Pl. v. 4. 378. Claſs and order, *Monœcia Pentandria*. Nat. Ord. *Compoſitæ nucamentaceæ*, Linn. *Corymbiferæ anomalæ*, Juſſ.

Gen. Ch. *Male Flowers* compound. *Cal.* Common Perianth of one leaf, flat, toothed, the length of the florets. *Cor.* compound, uniform, tubular, equal, forming a hemiſphere; partial erect, of one petal, funnel-ſhaped, five-cleft.

Stam.

Stam. Filaments five, very ſmall; anthers erect, parallel, diſtinct, furrowed. *Piſt.* Germen abortive; ſtyle thread-ſhaped; ſtigma peltate.

Female Flowers below the male, on the ſame plant. *Cal.* Perianth of ſeveral ovate leaves, containing a ſingle flower. *Cor.* none. *Piſt.* Germen ſuperior, ovate, muricated; ſtyles four; ſtigmas eight, oblong. *Peric.* Drupa dry, cloathed with rigid hooked briſtles, of four cells, with one oblong *ſeed* in each cell.

Eſſ. Ch. Male, Common calyx of one leaf, with many teeth. Corolla monopetalous, tubular, with five teeth. Receptacle naked.

Female, Calyx of many leaves, ſingle-flowered. Corolla none. Styles four. Drupa dry, briſtly, of four cells.

1. F. *artemiſioides*. Willd. Hort. Berol. v. 1, 2. t. 2. (Xanthium fruticoſum; Linn. Suppl. 418. Ambroſia arboreſcens; Mart. Mill. Dict. v. 1. n. 5. Lam. Dict. v. 1. 128.)—Leaves doubly-pinnatifid, toothed.—Native of Peru. It may be found in ſome curious gardens, and has of late been treated in England with ſome attention, from being ſuppoſed a white variety of *Chryſanthemum indicum*, but the miſtake was rectified when its miſerable flowers appeared. The *ſtem* is perennial, ſomewhat woody, leafy. *Leaves* deeply and doubly pinnatifid, pointed, toothed, moſt downy beneath. *Flowers* very late, greeniſh, the male reſembling thoſe of an *Artemiſia*, the female and the fruit being like a *Xanthium*.

2. F. *ambroſioides*. Willd. Sp. Pl. v. 4. 379. Cav. Ic. v. 2. 79. t. 200, excluding the ſynonyms. (Ambroſia maritima peruviana major; Hort. Reg. Pariſ. MSS.)—Leaves lanceolate, pinnatifid, toothed, with elongated points.—Native of Mexico and Peru. Larger than the laſt, with which Cavanilles confounds it. The *leaves* are much more elongated, and only ſimply pinnatifid, ſometimes undivided. The appendages on their *footſtalks*, on which Willdenow founds a part of his ſpecific character, ſeem to be only accidental and tranſient lobes.

This genus is akin on the one hand to *Ambroſia*, on the other to *Xanthium*, its habit and male flowers being moſt like the former, its fruit reſembling the latter; yet we do not ſee that it can ſatisfactorily be referred to either. How far the two ſpecies of *Franſeria* are permanently diſtinct may admit of ſome doubt, but they appear very different in foliage.

FRANTSILA, in *Geography*, a town of Sweden, in the government of Ulea; 30 miles S.E. of Braheſted.

FRANTZDORF, a town of Sileſia, in the principality of Neiſſe; four miles N. of Neiſſe.

FRANTZIUS, Wolfgang, in *Biography*, a learned German Lutheran divine, was born in Saxony in the year 1564. He received the early part of his education at Frankfort on the Oder, whence he was ſent to the univerſity of Wittemberg, where he was appointed profeſſor of hiſtory, and admitted to the degree of doctor of divinity in the year 1598: and in 1605 he was advanced to the theological chair in the ſame univerſity. He died in 1628, when he had attained his ſixty-fourth-year. He was a conſiderable writer, chiefly on theological ſubjects, and on the controverted doctrines of the day. Moreri.

FRANZBURG, in *Geography*, a town of Swediſh Pomerania, founded, in 1587, on the ſcite of a rich abbey; 14 miles S.S.W. of Stralſund. N. lat. 54° 10'. E. long. 12° 56'.

FRAPPE', *Fr.*, uſed ſubſtantively in *Muſic*, for the firſt note of a bar when the hand or foot *beats* the time. (See Thesis.) The French, in beating time, only mark the firſt note or accent of a bar, but indicate its other portions by different motions of the hand; as in compoſitions where the bar conſiſts of four crotchets, the firſt, or *down* part is beaten, at the ſecond, the hand is waved to the left, at the third lifted up, and at the fourth waved to the right. In triple time, if not very quick, at the firſt note the hand is beaten down, at the ſecond waved to the left, and at the third lifted up. The Italians *beat* the two firſt notes of a bar in triple time, and lift the hand *up* at the third. In common time of four crotchets they likewiſe *beat* the two firſt, and lift up the hand for the two others.

FRAPPING, in *Sea Language*, denotes the act of croſſing and drawing together the ſeveral parts of a tackle, or other complication of ropes, which had been already ſtraightened to their utmoſt extent, reſembling the operation of bracing up a drum, &c. The frapping increaſes the tenſion, and adds to the ſecurity acquired by the purchaſe. Hence the cat-harpings are no other than frappings to the ſhrouds.

Frapping *a Ship*, is the act of paſſing three, four, or five turns of a cable round the hull, or frame of a ſhip, in the middle, to ſupport her in a great ſtorm, when it is apprehended ſhe is not ſtrong enough to reſiſt the violent efforts of the ſea. This is ſeldom uſed, except in old ſhips. Falconer.

FRASCARUOLA, in *Geography*, a town of Italy, in the department of the Gogna; three miles N.E. of Valenza.

FRASCATI, or Frescati, an agreeable town, or rather village, in the Campagna di Roma, the ſee of a biſhop, who is a cardinal, ſeated on the declivity of a hill, about twelve miles from Rome. It derives its name from the coolneſs of the air, and freſh verdure of the fields about it; and it is celebrated for the palaces and country ſeats of Italian princes and cardinals, adorned with many beautiful paintings and ſculptures. The hills on which Freſcati is ſituated afford great abundance of water, which ſupplies fountains, caſcades, and water-works with which the villas are ornamented. This was the ſcite of the ancient Tuſculum, deſtroyed by the Romans in 1191, or very near it; and at the diſtance of about a mile and a half, it is generally believed, was the Tuſcan villa of Cicero, at a place now called Grotta Ferrata. Some Greek monks of the order of St. Baſil, flying from the perſecution of the Saracens in the 11th century, were permitted to build a convent on the ruins of Cicero's famous houſe; and they ſtill perform the ſervice in the Greek language. At a ſmall diſtance is the lake of Nemi, four miles in circumference, whoſe ſurrounding hills are covered with tall and ſhady trees. In ancient times there was a temple here, ſacred to Diana. The lake itſelf was called Speculum Dianæ, and Lacus Triviæ, and is the place mentioned in the 7th book of the Æneid, where the fury Alecto is deſcribed blowing the trumpet of war, at whoſe dreadful ſound the woods and mountains ſhook, and mothers, trembling for their children, preſſed them to their boſoms.

"Contremuit nemus, et ſylvæ intonuere profundæ,
Audiit et Triviæ longus lacus————
Et trepidæ matres preſſere ad pectora natos."

FRASERA, in *Botany*, ſo called by Walter, in honour of his indefatigable friend Mr. John Fraſer, nurſery and ſeedſman of Sloane-ſquare, to whom our gardens are indebted for many American plants. Walt. Fl. Carolin. 87. This is no other than *Swertia differmis* of Linnæus, which name was given it becauſe the flowers vary in number of parts from four to ſix; nor does it appear to us that it can be ſeparated from *Swertia*, though the corolla is much more ſtrongly and remarkably bearded than in S. *perennis*, and the ſtyles united into one.

FRASERBURGH, in *Geography*, a town in Aberdeenſhire, ſituated on the ſouth ſide of the promontory, called

Kinnaird's head, forty-one miles diſtant from Aberdeen, was erected into a borough of regality in 1613. The government is veſted in lord Saltoun, as provoſt, two bailiffs, a dean of guild, and council; and his lordſhip, as ſuperior, has the power annually of nominating and appointing the new governors, with the joint conſent of the old. The ſtreets are ſpacious and convenient, croſſing each other at right angles; the houſes well built, and, being covered with ſlate, give a neat and cheerful appearance to the place. Nearly in the centre ſtand two good public edifices, the town-houſe and priſon. In an area of about five hundred feet ſquare is an elegant croſs. This fine ſtructure conſiſts of an hexagonal pedeſtal, ſupported by three equidiſtant abutments of a ſimilar figure, and ſurmounted by a column twelve feet high, ornamented with the arms of Britain, and thoſe belonging to the family of Fraſer. At the weſt end of the town is an ancient quadrangular tower of three ſtories in height, which forms part of a building, intended for a college, but never carried further into effect. Sir Alexander Fraſer, in the year 1592, obtained a charter from the crown, empowering him to erect an univerſity "in ampliſſima forma," and in all reſpects like other univerſities within theſe realms; but from ſome latent and unauſpicious circumſtances the veſted powers of the charter were never executed. There are the remains alſo of ſeveral ancient towers, and veſtiges of religious ſtructures. According to the returns under the population act in 1801, the number of houſes was 490, and inhabitants 2215; of whom 217 were returned as employed in trade. The only manufacture is linen yarn, the quantity of which annually exported is to the amount of three or four thouſand pounds. Fraſerburgh poſſeſſes a ſmall, yet excellent harbour, having from eleven to ſixteen feet water, admitting ſhips of 300 tons burden to enter; and a good roadſtead contiguous, about one mile broad, and four in length, with ſafe anchorage ground; near which is the ſmall fiſhing village of Broadſea. Near the town is a caſtle, on a promontory called Kinnaird's head, bathed on two ſides by the ſea. On the top of this caſtle government lately erected a light-houſe, containing 20 lamps with reflectors. Fiſhing-banks for cod commence right off Kinnaird's head, ten leagues out at ſea. N. lat. 57° 33'. W. long. 1° 55.

In the immediate vicinity of the town ſtands Philorth houſe, ſurrounded by extenſive plantations, the ſeat of the right honourable George Fraſer, lord Saltoun and Abernethy.

FRASI, GIULIA, of Bologna, in *Biography*, a ſcholar of Brevio of Milan, came into England in 1743, the ſecond year of the earl of Middleton's opera regency, as third ſinger under Monticelli, and the Viſconti. Fraſi at this time was young and intereſting in her perſon, had a clear and ſweet voice, free from defects, and a ſmooth and chaſte ſtyle of ſinging; which, though cold and unimpaſſioned, pleaſed natural ears, and eſcaped the cenſure of critics. Galli arrived here at the ſame time, and after tranſplantation from Italy, they both took root in this country, and remained here in great public favour during many years. The firſt opera in which they appeared was Galuppi's "Enrico." Both theſe performers, by learning Engliſh, rendered themſelves important and neceſſary, on many occaſions, in our oratorios, theatres, and public concerts, when ſingers of a much higher claſs, without this qualification, could be of no uſe. In Italian ſinging, Fraſi's "Cheval de bataille" was the fine air, "Tremende occuri attroci," in Pergoleſi's Olimpiade, which Monticelli had ſung in the opera, but which ſuiting the compaſs and powers of Fraſi, ſhe ſung at concerts with great applauſe for ten years at leaſt, after the run of the opera was over. The great opera houſe being ſhut up this year on account of the rebellion, and popular prejudice againſt the performers, who being foreigners, were chiefly Roman catholics; an opera was attempted, April 7th, at the little theatre in the Haymarket, under the direction of Geminiani. Paſquali led the orcheſtra, and the celebrated and myſterious count St. Germain compoſed ſeveral new airs for it, particularly "Per pieta bell' idol mio," which was ſung by Fraſi, firſt woman, and encored every night. The reſt of his airs, and two by Brevio, Fraſi's maſter, which Walſh printed, were only remarkable for inſipidity. The firſt man's part was performed by Galli. The ſucceſs of this enterprize was inconſiderable, and the performances did not continue more than nine or ten nights. Prince Lobkowitz, who was here at this time, and conſtantly with count St. Germain, attended all the rehearſals, as well as the performances. In 1748 Fraſi performed the part of firſt ſerious woman in the comic opera at the Haymarket, when Pertici and Laſchi, the beſt buffos that we ever ſaw, were here, and Guadagni, then very young, was the firſt ſerious man. In 1750, there being a ſchiſm in the great theatre, the compoſer, Ciampi, and the performers, left the manager, Dr. Croza, and erected their ſtandard at the little theatre on the oppoſite ſide the way, where Fraſi performed the firſt woman's part in "Adriano in Siria," a new ſerious opera compoſed by Ciampi, in which Guadagni, then but a wild ſinger, with a very fine counter-tenor voice, appeared as firſt man; but after ſix thin houſes, this opera was ſuperſeded by the burlettas of the preceding winter. Though Fraſi was a great ſinger among the Engliſh vocal performers of theſe times, in 1754, ſhe was only rated as third woman at the great opera, giving place to the Viſconti and Paſſerini.

The next year, however, during the indiſpoſition of the Mingotti, Fraſi was often called upon as her *double*, till ſuſpicions ariſing that Mingotti's was a mere dramatic and political cold, the public was much out of humour, till ſhe reſumed her function in Metaſtaſio's admirable drama of "Demofoonte," in which ſhe acquired more applauſe, and augmented her theatrical conſequence beyond any period of her performance in England.

Fraſi's favour, however, was ſo eſtabliſhed in all our muſical performances elſewhere throughout the kingdom, that ſhe ſang at Ranelagh, at the triennial meetings at Worceſter, Hereford, and Glouceſter; at the two univerſities, and in London at the Swan, King's Arms, and Caſtle concerts, at the concert at Hickford's Room, Brewer-ſtreet, at all benefit concerts; and was the principal ſinger in Handel's oratorios during the laſt ten years of his life. Having come into this country at an early period of her life, ſhe pronounced our language in ſinging in a more articulate and intelligible manner than the natives; and her ſtyle being plain and ſimple, with a well-toned voice, a good ſhake, and perfect intonation, without great taſte and refinement, ſhe delighted the ignorant, and never diſpleaſed the learned. Yet with all this apparent proſperity, and a clear income of from 1100*l.* to 1800*l.* a year, ſhe literally died a beggar! And this in a great meaſure was occaſioned by poor Fraſi's too liberal ſpirit of hoſpitality towards the natives of Italy; who, coming to this country on mere ſpeculation, without any means of ſubſiſtence, preyed upon her, and conſtantly kept her in uneaſy circumſtances. By her want of economy, and little attention to her expences, they every year exceeded her income ſo much, that, at length, ſhe was obliged to quit this country to avoid being arreſted. Her youth and talents faded; her ſole reſources for her future ſubſiſtence were the penſions of ten or twelve Engliſh patrons, who ſubſcribed five guineas a year each during her and their proper lives. Among theſe was the late viſcount Barrington, and the ad-

miral his brother, the late lady Harrington, Meſſrs. Bradſhaw, Chamier, &c. For the convenience of receiving theſe benefactions ſhe ſettled at Calais, where, by the utmoſt parſimony, ſhe was able to ſupport a miſerable exiſtence, till, by the death of her benefactors, her income was at length reduced to ten or fifteen guineas a year, and we fear that her own death was ſomewhat accelerated by mere inanition!

Theſe melancholy particulars are here inſerted to warn our fair ſongſtreſſes againſt extravagance, and to remind them that faſhion and favour are ſeldom long-lived, no more than talents and beauty; and that expending their whole income in proſperous years is a ſure ſtep to indigence and miſery, if they ſhould arrive at old age. Such, alas! has been the fate, not only of Fraſi, but of the celebrated Cuzzoni, Galli, Gabrielli, Miſs Brent, &c. &c.

FRASIGNORE, in *Geography*, a town of Etruria; 7 miles N. of Piſtoia.

FRASLA, a town of the duchy of Stiria; 10 miles W. of Cilly.

FRASNES, a town of France, in the department of Jemmappe, and chief place of a canton in the diſtrict of Tournay. The place contains 3,094, and the canton 12,046 inhabitants, on a territory of 137½ kiliometres, in 13 communes.

FRASSEN, Claude, in *Biography*, was born near Peronne, in Picardy, in the year 1620; he was regularly educated in a convent belonging to the order of his native town, and after his profeſſion was ſent to purſue his ſtudies at the great Franciſcan convent at Paris. He took his degrees at the Sorbonne, and was admitted to that of doctor of divinity in the year 1662. He was frequently elected ſuperior to his order, and filled the office of theological profeſſor nearly thirty years. In 1682 he aſſiſted at a general chapter of his order, which was held at Toledo in Spain, and on account of his prudence and talents he was elected definitor general of the whole order. His wiſdom in conducting public official buſineſs was not confined to religious duties only; he was often conſulted by Lewis XIV., the parliament of Paris, the higher orders of the clergy, &c. on buſineſs of peculiar importance and intereſt. He died in 1711, in the ninety-fourth year of his age. He was author of "A ſyſtem of Philoſophy," in three volumes 4to. and of ſeveral theological and devotional pieces. Moreri.

FRASSETUM, in our *Old Writers*, is taken for a wood, or woody ground, where aſh grows. 1 Inſt. 4.

The word is a corruption of the Latin *fraxinetum*, which ſignifies the ſame.

FRASSINETO, in *Geography*, a town of Naples, in the province of Bari; 9 miles S.S.W. of Converſano.—Alſo, a town of Italy, in the Paduan; 2 miles N. of Montagnana.

FRATELLI, two ſmall iſlands in the Mediterranean; 25 miles W. from Scarpanto. N. lat. 35° 45'. E. long. 26° 22'.

FRATER Consanguineus, in *Law*, denotes a brother by the father's ſide; and *Frater uterinus*, a brother by the mother's ſide.

FRATERCULA, in *Ornithology*, a name by which Geſner and Aldrovand have called the *anas arctica cluſii*. See Alca *arctica*, and Puffin.

FRATER-HOUSE; the brethrens' hall, refectory, or eating-room in the ancient monaſteries was frequently called by this name.

FRATERIA, of *frater*, *brother*, a fraternity, brotherhood, or ſociety of religious perſons, who were bound to pray for the good health and life, &c. of their living brethren, and the ſouls of thoſe that were dead. In the ſtatutes of the cathedral church of St. Paul, London, collected by Ralph Baldock, dean, 1295, there is one chapter "De frateria beneficiorum eccleſiæ S. Pauli, &c."

Frateria, or *Phrateria*, in *Ancient Geography*, a town of Dacia, on the bank of the Mariza. Ptolemy.

FRATERNITY, Brotherhood, the relation or union of brothers, friends, partners, and aſſociates, &c.

Fraternity, in a *civil ſenſe*, is uſed for a guild, aſſociation, or ſociety of perſons, united into a body, for ſome common intereſt or advantage.

For the origin, uſe, &c. of fraternities, ſee Company and Gild.

Fraternity, in a *religious ſenſe*, is a ſociety of perſons meeting together to perform ſome exerciſes of devotion, or divine worſhip.

In the Romiſh church, ſuch fraternities are very numerous and conſiderable, being moſt of them eſtabliſhed by royal patents; as the fraternity of the Roſary; the fraternity of the Scapulary of St. Francis's Cord; ſee Cordeliers and Franciscans. The biſhop may hinder the eſtabliſhment of any ſuch fraternity in his dioceſe.

At Rome there is a fraternity, called the archi-fraternity, or grand fraternity, under the title of "Our Lady of the Suffrages," eſtabliſhed in favour of the ſouls in purgatory, approved and confirmed by a bull of pope Clement VIII. in 1594. See Brethren and Brothers.

There are nine different ſorts of fraternities, or confrairies, in France, *viz.* 1. Of Devotion. 2. Of Charity, or Mercy. 3. Of Penitents, under divers names. 4. Of Pilgrimage. 5. Of Merchants to procure the divine favour on their endeavours. 6. Of Officers of Juſtice. 7. Of the ſufferings of Chriſt. 8. Of Arts and Trades of divers kinds. And, 9. Of Factions.

Fraternities, in Latin called *ſodalitates*, derive their origin from the heathens, as is ſhewn by Polydore Virgil, in his book "De Inventoribus Rerum." But the good uſe made of them by the Chriſtians has effectually purged them of any impurities derived from ſo ill a ſource.

Numa Pompilius is ſaid to have eſtabliſhed fraternities of all arts and trades in ancient Rome, and to have preſcribed the ſacrifices each profeſſion was to perform to the patrons or tutelary gods he had aſſigned them.

Fraternity *of the holy Trinity*. See Trinity.

Fraternity is alſo a title or quality which kings and emperors gave to each other; ſo alſo do biſhops and monks. We meet with it frequently in authors under the eaſtern empire, both Greek and Latin: the Greek term is ἀδελφότης, *fraternitas*.

Fraternity *of Arms* was an alliance, or aſſociation in arms, anciently concluded between two knights, who thereby agreed to go together, ſhare their fortunes, and mutually aſſiſt each other againſt all the world.

Bertrand du Gueſclin and Oliver Cliſſon ſwore a fraternity of arms in the year 1579, laying their hands on the goſpels. Hiſt. de Bret. tom. i. p. 395.

Fraternity *of St. Catharine*. See Catharine.

FRATING, or Wrateni, in *Geography*, a town of Moravia, in the circle of Znaym; 22 miles W.N.W. of Znaym.

FRATINO, a town of Italy, in Friuli; 25 miles S.W. of Udina.

FRATRES Arvales. See Arvales.

Fratres *Conjurati*, in our *Ancient Law-books*, &c. denote ſworn brothers, or companions.

Sometimes they are ſo called who were ſworn to defend the king againſt his enemies, leg. W. 1. cap. 59. "Præcipimus, ut omnes liberi homines ſint fratres conjurati ad monarchiam

narchiam noſtram & regnum noſtrum contra inimicos pro poſſe ſuo defendendam."

FRATRES *Gaudentes*. See *Joyful* BROTHERS.

FRATRIAGE, FRATRIAGIUM, or *Frerage*, the partition among brothers, or coheirs, coming to the ſame inheritance or ſucceſſion.

FRATRIAGE is more particularly uſed for that part of the inheritance which comes to the youngeſt brothers.

Whatever the cadets, or younger brothers, poſſeſs of the father's eſtate, they poſſeſs *ratione fratriagii*, and they are to do homage to the elder brother for it; in regard he is to do homage for the whole to the ſuperior lord.

FRATRICELLI, in *Eccleſiaſtical Hiſtory*, an enthuſiaſtic ſect of Franciſcans, which roſe in Italy, and particularly in the marquiſate of Ancona, about the year 1294.

The word is an Italian diminutive, ſignifying fraterculi, or little brothers; and was here uſed as a term of deriſion, as they were moſt of them apoſtate monks, whom the Italians call *fratelli*, or *fratricelli*.

For this reaſon the term fratricelli, as a nickname, was given to many other ſects, as the Cathariſts, the Waldenſes, &c. however different in their opinions and in their conduct. But this denomination, applied to the auſtere part of the Franciſcans, was conſidered as honourable. See FRANCISCANS.

The founders were P. Mauraro, and P. de Foſſombroni, who having obtained of pope Celeſtin V. a permiſſion to live in ſolitude, after the manner of hermits, and to obſerve the rule of St. Francis in all its rigour, ſeveral idle vagabond monks joined them, who, living after their own fancies, and making all perfection to conſiſt in poverty, were ſoon condemned by pope Boniface VIII. and his ſucceſſor, and the inquiſitors ordered to proceed againſt them as heretics; which commiſſion they executed with their uſual barbarity. Upon this, retiring into Sicily, Peter John Oliva de Serignan had no ſooner publiſhed this Comment on the Apocalypſe, than they adopted his errors.

They held the Romiſh church to be Babylon, and propoſed to eſtabliſh another far more perfect one; they maintained, that the rule of St. Francis was the evangelical rule obſerved by Jeſus Chriſt, and his apoſtles.

They foretold the reformation of the church, and the reſtoration of the true goſpel of Chriſt, by the genuine followers of St. Francis, and declared their aſſent to almoſt all the doctrines which were publiſhed under the name of the abbot Joachim, in the Introduction to the Everlaſting Goſpel, a book publiſhed in 1250, and explained by one of the ſpiritual friars, whoſe name was Gerhard. Among other enormities inculcated in this book, it is pretended that St. Francis was the angel mentioned in Rev. xiv. 6. and had promulgated to the world the true and everlaſting goſpel of God; that the goſpel of Chriſt was to be abrogated in 1260, and to give place to this new and everlaſting goſpel, which was to be ſubſtituted in its room; and that the miniſters of this great reformation were to be humble and bare-footed friars, deſtitute of all worldly employments.

Some ſay they even elected a pope of their new church; at leaſt they appointed a general, with ſuperiors, and built monaſteries, &c. Beſide the opinions of Oliva, they held, that the ſacraments of the church were invalid; becauſe thoſe who adminiſtered them had no longer any power or juriſdiction.

They were condemned afreſh by pope John XXII., in conſequence of whoſe cruelty they regarded him as the true antichriſt; but ſeveral of them returning into Germany, were ſheltered by Lewis, duke of Bavaria, the emperor.

There are authentic records, from which it appears, that no leſs than two thouſand perſons were burnt by the inquiſition, from the year 1318 to the time of Innocent VI. for their inflexible attachment to the poverty of St. Francis. The ſeverities againſt them were again revived towards the cloſe of the fifteenth century by pope Nicholas V. and his ſucceſſors. However, notwithſtanding all the perſecutions which this ſect endured, they were not ſufficient to extinguiſh it; for it ſubſiſted until the times of the reformation in Germany, when its remaining votaries adopted the cauſe, and embraced the doctrine and diſcipline of Luther. And this has led the popiſh writers to charge the fratricelli with many enormities, ſome of which are recounted by M. Bayle, art. *Fratricelli*.

The fratricelli had divers other denominations; they were called fratricelli, according to ſome, becauſe they lived in community, in imitation of the primitive Chriſtians, or rather through the humility of the founder of the Franciſcan order, to which the fratricelli originally belonged; *dulcini*, from one of their doctors; *bizochi*, *beguins*, and *beghardi*.

FRATRICIDE, of *frater*, *brother*, and *cædo*, *I kill*, the crime of murdering one's brother. See PARRICIDE.

Cain committed the firſt fratricide; and the empire of Rome began with a fratricide.

FRATTA, in *Geography*, a town of Italy, in the duchy of Urbino; 32 miles S. of Urbino. N. lat. 43° 18'. E. long. 12° 18'.—Alſo, a town of Italy, in Friuli; 18 miles S.S.W. of Udina.

FRATTA, *La*, a town of Italy, in the Poleſino de Rovigo, on the Scortico, containing about 6000 inhabitants.

FRAUBRUNNEN, or FRAUENBRUN, a town of Switzerland, and ſeat of a bailiwick, in the canton of Berne, deriving its name from a celebrated monaſtery founded in the year 1246; 7 miles N. of Berne.

FRAUD, FRAUS, a ſecret, underhand deceit, or injury, done to any one. See CHEATS and DECEIT.

To export or import goods by fraud, or fraudulently, is to do it by indirect ways, in order to avoid the paying of duty, &c. if they be permitted goods; or if they be contraband goods, to avoid the penalties adjudged by the laws.

A fraudulent conveyance of lands or goods to deceive creditors, or to defraud purchaſers, is void in law; and the perſons juſtifying or putting off ſuch grants as good, ſhall forfeit a year's value of the lands, and the full value of the goods and chattels, and likewiſe be impriſoned for half a year. Stat. 3 Hen. VII. c. 4. Stat. 50 Ed. III. c. 6. Stat. 13 Eliz. c. 5. made perpetual by ſtat. 29 Eliz. c. 5. Stat. 27 Eliz. c. 4, made perpetual by ſtat. 39 Eliz. c. 18. The ſeveral marks of fraud in a gift or grant of goods are the following: 1. If it be general, without exception of ſome things of neceſſity. 2. If the donor ſtill poſſeſſes and uſes the goods. 3. If the deed be made in ſecret. 4. If there be a truſt between the parties. 5. If it be made while the action is depending. When a perſon is party to a fraud, all that follows thereupon will be intended to be done by him, though fraud ſhall not be preſumed or adjudged to be ſo, until it be found by a jury. 10 Rep. 56. All frauds and deceits, for which there is no remedy by the ordinary courſe of law, are properly cognizable in equity; and it is admitted, that matters of fraud were one of the chief branches to which the juriſdiction of chancery was originally confined. 4 Inſt. 84.

Among a variety of caſes, in which relief has been given againſt frauds, we may ſelect the following: Whenever fraud or ſurpriſe can be imputed to, or collected from the circumſtances of the tranſaction, equity will interpoſe and relieve againſt it. It is ſaid, however, that it muſt not be underſtood, from caſes of this kind being generally brought into

ſuto equity, that the courts of law are incompetent to relieve; for where the fraud can be clearly eſtabliſhed, courts of law exerciſe a concurrent juriſdiction with courts of equity, and will relieve by making void the inſtrument obtained by ſuch corrupt agreement or fraud. 1 Burr. 396. Wood's Inſt. 295. Therefore, where the obligor was an unlettered man, and the bond was not read over to him, he was allowed to plead this circumſtance in an action on the bond. 9 Hen. V. 15, cited 11 Co. 27 *b*.

So if the bond be in part read to an unlettered man, and ſome of its material parts be omitted or miſrepreſented. 2 Rol. Abr. 28. p. 8. It is obſervable that lord Coke, in the ſame paſſage where he confines the juriſdiction of courts of equity to ſuch "frauds, covin, and deceit, for which there is no remedy by the ordinary courſe of law," ſeems to admit that all frauds were not relievable at law. See 3 Inſt. 84. The chancery may decree a conveyance to be fraudulent, merely for being voluntary, and without any trial at law; yet it has been maintained, that fraud, or not, was triable only by a jury. Pre. Ch. 14, 15. Although courts of equity will not relieve againſt agreements merely on the ground of the conſideration being inadequate, yet if there be ſuch inadequacy as to ſhew, that the perſon did not underſtand the bargain he made, or was ſo oppreſſed that he was glad to make it, knowing its inadequacy, it will ſhew a command over him which may amount to a fraud. 2 Bro. C. R. 175. 1 Bro. C. R. 558. 2 Vez. 155. 2 P. Wms. 203. It ſeems agreed, tha if a woman, on the point of marriage, charge or convey her property to a mere ſtranger, for whom ſhe was not under even a moral obligation to provide, ſuch conveyance will be deemed a fraud on the marital rights. 2 C. R. 41. 2 Vez. 264. If A. has a prior incumbrance on an eſtate, and is a witneſs to a ſubſequent mortgage, but does not diſcloſe his own incumbrance, this is ſuch a fraud in him for which his incumbrance ſhall be poſtponed. 2 Vern. 151. 554. So if A. having a mortgage on a leaſehold eſtate, lends the mortgage deed to the mortgagor, with an intent to borrow more money; that is ſuch a fraud in the mortgagee, for which his mortgage ſhall be poſtponed to the ſubſequent incumbrance. 2 Vern. 726. 1 Eq. Abr. 321. If a ſecurity be obtained from a perſon by fraud, upon a pretence of a demand that is fictitious, it will be relieved againſt in equity. 2 Vern. 123. 632. There are likewiſe ſeveral inſtances where a parol agreement intended to be reduced into writing, but prevented by fraud, has been decreed in equity, notwithſtanding the ſtatute of frauds and perjuries; as where upon a marriage-treaty, inſtructions were given by the huſband to draw a ſettlement, which he privately countermanded, and afterwards drew in the woman by perſuaſions and aſſurances of ſuch ſettlement to marry him, it was decreed, that he ſhould make good the ſettlement. 1 Eq. Ab. 19. So where a parol agreement was concerning lending of money as a mortgage, and the covenants propoſed were an abſolute deed from the mortgagor, and a deed of defeaſance from the mortgagee, and after the mortgagee had got the deed of conveyance, he refuſed to execute the defeaſance; it was decreed againſt him on the point of fraud. 1 Eq. Ab. 90.

The ſtatute of frauds, 29 Car. II. cap. 3. requires that contracts and agreements, leaſes, and deviſes of land, be in writing. And deviſes of land, rents, &c. are deemed fraudulent and void againſt creditors, upon bonds or other ſpecialties, 3 and 4 William and Mary, cap. 14. made perpetual by ſtat. 6 William III. c. 14.

And every ſuch creditor ſhall have his action of debt upon his bonds and ſpecialties againſt the heir at law of ſuch obligor, and ſuch deviſees jointly. This ſtatute, however, excepts diſpoſitions for the payment of debts and raiſing portions for children, in purſuance of marriage contracts made before marriage; it farther provides, that where any heir at law ſhall be liable to pay his anceſtor's debts, in reſpect of lands deſcended to ſuch heir, and ſhall alien the ſame before action brought, ſuch heir ſhall be anſwerable to the creditor in an action of debt to the value of the land aliened; but the lands *bonâ fide* aliened before action brought ſhall not be liable. Every deviſee, however, made liable by the ſtatute, ſhall be chargeable in the ſame manner as the heir, though the lands deviſed ſhall be aliened before action brought.

It may be laid down as a general rule, that without the expreſs proviſion of any act of parliament, all deceitful practices in defrauding, or endeavouring to defraud, another of his known right, by means of ſome artful device, contrary to the plain rules of common honeſty, are condemned by the common law, and puniſhable according to the heinouſneſs of the offence. Co. Litt. 36. Dyer 295. It is alſo a rule, that a wrongful manner of executing a thing ſhall avoid a matter that might have been executed lawfully. Co. Litt. 35. 357. Rol. Abr. 420. 549. Poph. 64. 100. As to frauds in contracts and dealings, the common law ſubjects the wrong-doer, in ſeveral inſtances, to an action on the caſe; as if a perſon, having the poſſeſſion of goods, ſell them to another, affirming them to be his own, when in truth they are not, an action on the caſe lies. 1 Rol. Abr. 90. Cro. Jac. 474. If on a treaty for the purchaſe of a houſe, the defendant affirms the rent to be more than it is, whereby the plaintiff is induced to give more than the houſe is worth, this is a fraud. 1 Salk. 211. 1 Lev. 102. 1 Sid. 146. 1 Keb. 510. 518. 522. S. P.

FRAUDULENT DEEDS. See DEED.

FRAUDULENT *Deviſes*. See the article FRAUD. See alſo DEVISE and WILL.

FRAUENBERG, or PRZINDA, in *Geography*, a town of Bohemia, in the circle of Pilſen; 5 miles S. W. of Hayd.

FRAUENBERG, or *Hluboka*, a town of Bohemia, in the circle of Prachatitz; 12 miles S. E. of Woodnian.

FRAUENBERG, a town of Pruſſia, in the province of Ermland, ſituated on the Friſch-haff, built in the year 1279. The celebrated Copernicus was a canon of this church, and died here in 1543; 16 miles N. E. of Elbing. N. lat. 54° 20'. E. long. 19° 10'.—Alſo, a town of the duchy of Courland; 30 miles W. of Mittau.

FRAUENDORF, a town of Germany, in the biſhopric of Bamberg; 14 miles N. N. E. of Bamberg.—Alſo, a town of the New Mark of Brandenburg; 10 miles S. of Cuſtrin.

FRAUENFIELD, a ſmall town, or rather village of Switzerland, and nevertheleſs the capital of the bailliage of Thurgau, containing ſcarcely 1000 inhabitants; and only remarkable as the place where, ſince 1712, the deputies of the Swiſs cantons have been accuſtomed to aſſemble at the general diet; 20 miles N. E. of Zurich.

FRAUENMARCK, a town of Hungary; ſix miles N. E. of Levens.

FRAUENPRIESNITZ, a town of Germany, in Thuringia; 15 miles W. of Weimar.

FRAUENSTEIN, a town of Germany, in the circle of Erzgeburg, on the Mulda; 18 miles S. S. W. of Dreſden. N. lat. 50° 43'. E. long. 13° 31'.

FRAUENTHAL, a town of the duchy of Stiria; 10 miles S. of Voitzberg.—Alſo, a town of the principality of Anſpach; five miles N. E. of Creglingen.

FRAU-

FRAUENWALD, a town of Germany, in the county of Henneberg; four miles N. E. of Schleuſingen.

FRAUHOFEN, a town of Bavaria; three miles S. of Landſhut.

FRAUNBERG, a town of the duchy of Stiria; ſeven miles E. S. E. of Oberwoltz.

FRAUREUTH, a town of Germany, in the county of Reus; ſix miles N. E. of Greitz.

FRAUS Legis; if a perſon, having no manner of title to a houſe, procure an affidavit of the ſervice of a declaration in ejectment, and thereupon gets judgment; and, by virtue of a writ of *hab. fac. poſſeſſionem*, turns the owner out of poſſeſſion of the houſe, and ſeizes and converts the goods therein to his own uſe, he may be puniſhed as a felon; becauſe he uſed the proceſs of the law with a felonious purpoſe, *in fraudem legis*.

FRAUSTADT, or Frauenstadt, in *Geography*, a town of the duchy of Warſaw, on the frontiers of Sileſia, where, in the year 1706, the Saxons were defeated by the Swedes. It contains three proteſtant churches, and is chiefly inhabited by Germans, who trade principally in cattle and wool; 170 miles N. N. W. of Breſlaw.

FRAXINELLA, in *Botany*, the diminutive of *Fraxinus*, a little aſh, alluding to the form of the leaves. See Dictamnus.

Fraxinella, in the *Materia Medica*, is the Dictamnus *albus*, which ſee. The root, which is the only part directed for medicinal uſe, has, when freſh, a moderately ſtrong, not diſagreeable ſmell; and to the taſte diſcovers a pretty ſtrong and very durable bitterneſs, which is taken up by both watery and ſpirituous menſtrua; and on inſpiſſating the filtered tinctures, remains entire in the extracts; the aqueous extract is in much larger quantity than the ſpirituous, and proportionably weaker in taſte. This root was formerly uſed as a ſtomachic, tonic, and alexipharmic, and was ſuppoſed to be an efficacious medicine in removing uterine obſtructions, and deſtroying worms; but it ſunk almoſt entirely into diſuſe, till Baron Stoerck brought it into notice by publiſhing ſeveral caſes of its ſucceſs in tertian intermittents, worms, (lumbrici,) and menſtrual ſuppreſſions; in which caſes he employed the powdered root to the extent of a ſcruple twice a day. He alſo uſed a tincture, prepared of two ounces of the freſh root digeſted in 14 ounces of ſpirit of wine; of this 20 to 50 drops, two or three times a-day, were ſucceſsfully preſcribed in epilepſies, &c. and when joined with ſteel, this root, it is ſaid, was of great ſervice to chlorotic patients. Nevertheleſs, though the dictamnus is a medicine of conſiderable power, we may ſtill ſay with Haller, "Nondum autem vero pro dignitate exploratus eſt." Woodville, Med. Bot.

FRAXINUS, in *Botany*, the Aſh; ſo called by the Romans, whether from φραττω, to hedge in or encloſe, or from *fragoſus*, rough and rocky; the former alluding to its poſſible, though not general, uſe, and the latter to its occaſional, though not uſual, places of growth; we really cannot decide, but we have nothing better to offer. Linn. Gen. 550. Schreb. 736. Sm. Fl. Brit. 12. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 444. Juſſ. 105. Tourn. t. 343. Gærtn. t. 49. Claſs and order, *Diandria Monogynia*. (*Polygamia Dioecia*; Linn.) Nat. Ord. *Sepiariæ*, Linn. *Jaſmineæ*, Juſſ.

Gen. Ch. *Cal.* either wanting, or a ſmall Perianth of one leaf, in four deep ſegments, upright and acute. *Cor.* either wanting, or in four long, linear, acute, upright ſegments. *Stam.* Filaments two, erect, much ſhorter than the corolla; anthers erect, oblong, with four furrows. *Piſt.* Germen inferior, ovate, compreſſed; ſtyle cylindrical, upright; ſtigma thickiſh, cloven. *Peric.* Capſule ovate-oblong, leafy in the upper part, of two cells, one of which is generally abortive. *Seeds* ſolitary, pendulous, lanceolate, compreſſed, cloathed with ſhining powder.

Eſſ. Ch. Calyx none, or deeply four-cleft. Corolla none, or deeply four-cleft. Capſule ſuperior, of two cells, leafy at the top, compreſſed. Seeds ſolitary, pendulous. Some flowers have no ſtamens, ſome no ſtigma.

E. *excelſior* has neither calyx nor corolla. Its flowers have always a greater or leſs proportion of female ones intermixed.—*F. Ornus*, though aſſerted by Linnæus to bear perfect or united flowers only, was found by Sibthorp to have ſome few with an abortive germen and no ſtyle, and ſtill more with a perfect piſtil, but no ſtamens.

1. F. *Ornus*. Manna, or Flowering Aſh. Linn. Sp. Pl. 1510. Sm. Fl. Græc. Sibth. v. 1. 4. t. 4. Woodv. Med. Bot. t. 36. Willd. Baumz. 115. Ehrh. Pl. Off. 270. Arb. 160. Leaflets elliptic-oblong, pointed, bluntly ſerrated. Flowers with a corolla.—Native of the warmeſt parts of Europe. Common on the higheſt moſt rocky mountains of Greece, and not rare in the ſouth of Italy. This is the μελια of the ancient Greeks, μέλεσς of the modern inhabitants of the ſame country. Manna is obtained from the ſap that flows from wounds in the trunk, and according to the information of Mr. Hawkins, recorded in the Flora Græca, is collected at preſent in the peninſula of Mina only. The tree is ſometimes ſeen in our ſhrubberies, and in May or June, when covered with its innumerable light delicate whitiſh bloſſoms as with a muſlin veil, affords a very agreeable ſpectacle. The *leaves* conſiſt of two or three pair, with an odd one, of oppoſite, ſlightly ſtalked, leaflets, various in breadth, ſmooth, light green; their ſerratures ſmall, rounded, numerous and obtuſe. *Panicles* about the ends of the branches, axillary, much-compounded, many-flowered. *Capſules* ſmaller than thoſe of the common aſh, ſeldom ripened in England.

2. F. *rotundifolia*. Round-leaved Aſh. Mill. Dict. ed. 8. n. 2. Ait. Hort. Kew. v. 3. 445. Lam. Dict. v. 2. 546. Willd. Baumz. 116. t. 6. f. 1.—Leaflets roundiſh, acute, ſharply ſerrated. Flowers with a corolla.—Native of the Levant. Manna ſeems to be collected from this indifferently with the preceding. It is known by the ſharp ſpreading ſerratures of the *leaflets*. Their breadth or roundneſs is a variable circumſtance in the former, and poſſibly in the preſent ſpecies. Miller makes a whimſical miſtake in terming the flowers *coloured*, from a wrong tranſlation, and indeed a wrong tranſcript, of the words *floribus corollatis* in Linnæus. Plukenet's *F. alepenſis*, Phyt. t. 182. f. 4, ſeems manifeſtly this ſpecies, as Lamarck makes it, though Willdenow refers it to *parvifolia*, n. 9.

3. F. *americana*. American Aſh. Linn. Sp. Pl. 1510. Willd. Baumz. 116. (F. acuminata; Lam. Dict. v. 2. 547.)—Leaflets ſtalked, oblong, pointed, ſlightly ſerrated; glaucous beneath. Capſules cylindrical at the baſe.—Native of Carolina, Pennſylvania, &c.—The taper-pointed *leaflets*, very ſlightly ſerrated, glaucous beneath, and of an oblong lanceolate figure, diſtinguiſh this ſpecies. The *capſules* are remarkable for being ſcarcely at all compreſſed, but nearly cylindrical, in the part where the ſeed is lodged. A jagged permanent *calyx* is viſible on the fruit, which leads us to ſuppoſe it has alſo a *corolla*, but of that we have no account. This aſh is ſaid to thrive in moiſt low ſituations. It grows to a conſiderable height, and makes a handſome tree.

4. F. *juglandifolia*. Walnut-leaved Aſh.—Lam. Dict. v. 2. 548. Willd. Baumz. 117.—"Leaflets ſtalked, ovate, opaque, toothed; glaucous, with downy veins beneath. Branches ſmooth. Flowers with a calyx."—Native of North

North America. It bloſſoms at the end of April or beginning of May, and is a middle-ſized tree, not remarkable for beauty. The *leaves* are large, reſembling thoſe of a Walnut, and differ from the laſt in being toothed, and not ſo much pointed. The *buds* are ſmall, compreſſed and reddiſh. The *flowers* have a calyx, but we find no mention of a corolla. *Lamarck, Willdenow.*

5. F. *caroliniana.* Narrow-leaved Carolina Aſh.—Lam. Dict. v. 2. 548. Willd. Baumz. 119. (F. carolinenſis, foliis anguſtioribus, utrinque acuminatis, pendulis; Cateſby's Carolina, t. 80?)—"Leaflets ſtalked, lanceolate, toothed, ſhining, ſmooth. Branches ſmooth. Flowers with a calyx."—Native of North America. Differs from the preceding in having narrower, more pointed *leaves*, not white beneath, toothed, of a bright ſhining green. Lamarck deſcribes a variety with ſtill narrower leaves, of a brighter green beneath, and of an agreeable aſpect, which he conceives to be probably what Cateſby has figured.

6. F. *pubeſcens.* Downy-leaved Aſh.—Lam. Dict. v. 2. 548. Willd. Baumz. 119. Walt. Carol. 254?—"Leaflets ſtalked, elliptic-ovate, ſerrated; downy beneath, as well as the footſtalks and branches. Flowers with a calyx."—A *tree* twenty feet high, of little beauty, native of North America. The leaflets are rather more numerous than in any of the other American kinds, being uſually ſeven or nine, finely ſerrated, clothed underneath with ſoft down. The *footſtalks* and young *branches* are likewiſe downy. *Flowers* with a calyx, but no corolla. *Lamarck, Willdenow.*

7. F. *ſambucifolia.* Elder-leaved Aſh.—Lam. Dict. v. 2. 549. Willd. Baumz. 121.—"Leaves ſeſſile, ovato-lanceolate, ſerrated, rugged, ſhining; branchings of their veins downy beneath."—Native of North America. A *tree* of vigorous growth, twenty or twenty-five feet high, known by its ſeſſile *leaflets*, and their dark-green colour. The terminal one only is ſtalked. The whole number of leaflets is ſeven. They are naked, except the ribs at the back. Of the flowers we have no account.

Of this and the three immediately preceding we have no knowledge but from the works of Lamarck and Willdenow. The former ſaw them growing in the garden at Paris. They may perhaps all be to be found among our nurſeries in England, but botaniſts have not taken the pains to ſtudy them. As ſo much has been done to clear up the far more difficult genera of *Salix* and *Pinus*, it is to be hoped thoſe of *Fraxinus* and *Quercus* will one day receive elucidation, from ſome ſcientific hand. The plants muſt be obſerved, and ſpecimens collected, when in flower, in early and in full-grown foliage, with the fully formed capſules.

8. F. *excelſior.* Common Aſh. Linn. Sp. Pl. 1509. Lam. Dict. v. 2. 544. Engl. Bot. t. 1692.—Leaflets ſlightly ſtalked, elliptic-lanceolate, pointed, ſerrated. Flowers without calyx or corolla.—Native of Europe and the north of Aſia, in a light ſpringy (but not marſhy) ſoil, eſpecially if marly or calcareous. When planted in bogs, it contributes much to drain them. It will grow in almoſt any ſituation, even in hard clay and dry gravel, though Lamarck juſtly obſerves that poor dry ſandy ground is fatal to this tree. Its ſmooth ſtately *ſtem* riſes to a great height, with ſpreading, rather drooping, branches. *Buds* ſhort, thick, black and downy. *Leaves* compoſed of five or ſix pair of nearly ſeſſile, ovate, or ovato-lanceolate, pointed, ſerrated, ſmooth leaflets. The *flowers* come forth in April, before the leaves, from lateral buds, below the leaf-buds, and are greeniſh and inconſpicuous, without any traces of calyx or petals. *Capſules* pendulous, compreſſed, often twiſted, pointed.

a. Weeping Aſh. This is a variety, whoſe branches are quite pendulous, and ſweep on the ground. It is well adapted for bowers, and is now common in the gardens of this country.

b. Simple-leaved Aſh. Fraxinus ſimplicifolia; Willd. Baumz. 121. t. 3. f. 2. We have heard of wild plants of this kind in Cambridgeſhire and in Kent. The large ſimple *leaves* give it a totally different aſpect from the Common Aſh, but have rather ſingularity than beauty to recommend them. Some of them however are occaſionally pinnate. Willdenow eſteems this Aſh a diſtinct ſpecies, and we have heard ſurmiſes to the ſame purpoſe, which we have not yet materials to refute or confirm. Propagation by ſeed ſhould decide the queſtion.

F. *excelſior* is valuable for its tough and hard wood, which ſerves for many different purpoſes. The varieties are propagated by grafting.

9. F. *parvifolia.* Small-leaved Aſh. Lam. Dict. v. 2. 546. Willd. Baumz. 124. t. 6. f. 2. (F. rotundifolia; Ehrh. Pl. Off. 280.)—Leaflets ſlightly ſtalked, ovate, pointed, ſerrated; wedge-ſhaped at the baſe. Flowers without calyx or corolla. Capſules cylindrical at the baſe.—Native of the Levant. This has been confounded with the Manna Aſh, from which it is very diſtinct, being much more like the Common Aſh in its *buds*, and agreeing with the latter in the colour and ſtructure of its *flowers*, which have neither calyx nor corolla. The *capſules*, according to Lamarck, are narrow, and nearly cylindrical, their wing dilated upwards, and abrupt. The *leaflets* are ſhorter and broader than in *F. excelſior*. Ehrhart appears to have confounded the ſpecies before us with Miller's *F. rotundifolia*, our n. 2, and ſeveral perſons miſtake it for the tree which produces Manna, F. *Ornus*, n. 1.

FRAXINUS, in *Gardening*, compriſes plants of the hardy deciduous tree kind, of which the ſpecies cultivated for timber are: the common aſh-tree (F. excelſior), the manna aſh-tree (F. rotundifolia), the flowering aſh-tree (F. ornus), and the American aſh-tree (F. americana).

Of the firſt ſort there are varieties, with ſimple leaves, lobed, and even ternate; with pendulous branches; or weeping aſh, with variegated leaves, yellow and white; or gold-ſtriped and ſilver-ſtriped.

And of the third ſort there is a variety, the dwarf flowering aſh.

Of the fourth ſort there are the white American aſh, and the red American aſh. And there is a third variety named the black aſh, in which the ſtem is erect, branching, twenty or thirty feet in height, with large very dark leaves compoſed of three or four pairs of lobes and an odd one, ſmall flowers of a greeniſh colour, and broad blackiſh fruit. Other varieties may alſo be found in the nurſeries which are not leſs curious than thoſe that have been mentioned above.

Method of Culture.—Theſe plants may all of them be increaſed with facility by ſeeds, which in the common ſort ſhould be ſown in the autumn; and in the others, as ſoon as they can be obtained in the ſpring, on beds of light mould over the ſurface, raking them into the depth of nearly an inch. The young plants ſhould be afterwards kept clear from weeds, and when they have had one or two years growth they ſhould be removed into nurſery rows, and placed two feet aſunder, and one diſtant in the rows, where they muſt remain till fit for being planted, where they are to grow in the natural ground.

The three laſt ſorts may likewiſe be raiſed by budding or ingrafting upon common aſh ſtocks, when of the ſize of a good bean ſtem. This buſineſs ſhould be performed about

the latter end of ſummer; but the plants raiſed in this mode are not ſo fine as thoſe from ſeed, on account of the ſtocks growing with more rapidity than the heads of the plants.

Theſe are the only methods by which the variegated varieties can be increaſed.

All the ſorts may be introduced as ornamental trees; but thoſe of the American kind are the moſt proper in ſmall plantations, ſhrubberies, and other ornamented grounds.

The firſt ſort is highly uſeful as a timber-tree, and ſhould be much more attended to than has lately been the caſe, as wood of the aſh kind is becoming extremely ſcarce in many ſituations. For various uſes in huſbandry, and ſeveral other purpoſes, there is no other ſort of wood that can ſupply its place. It grows well in dry places where the ſoil is mellow, though it may not have any great depth, but ſucceeds beſt in ſouthern expoſures. See Ash-*tree*.

FRAY literally ſignifies to fret; as cloth or ſtuff does by rubbing, or over-much wearing.

Among hunters a deer is ſaid to fray his head, when he rubs it againſt a tree, to cauſe the ſkins of his new horns to come off.

FRAYLES, in *Geography*, an iſland near the coaſt of New Andaluſia, in Terra Firma.

Frayles, *Los*, a cluſter of ſmall iſlands in the Weſt Indies, about 6 miles N.E. from the iſland of Margarita. N. lat. 11° 15'. W. long. 63° 46'.

FREA, Freia, or *Frigga*, in *Mythology*, the wife of Odin, and, next to him, the moſt revered divinity among the heathen Saxons, Danes, and other northern nations. As Odin was reputed to be the father, Frea was eſteemed the mother of all the other gods. In the moſt ancient times, Frea was the ſame with the goddeſs Hertha, or Earth, which was devoutly worſhipped by the Angli and other German nations. See Hertha and Odin. From the name of this divinity, ſome have derived that of Friday, the ſixth day of the week.

FREAM, in *Agriculture*, a term applied to ſuch arable or ploughed land as is worn out or exhauſted, and is laid fallow till it recovers.

Fream, among *Sportſmen*, a term uſed for the noiſe of a boar in rutting time.

FRECHILLA, in *Geography*, a town of Spain, in the province of Leon; 17 miles N.W. of Palencia.

FRECKELBEN, a town of Germany, in the principality of Anhalt-Deſſau; 30 miles W.S.W. of Deſſau.

FRECKLE, in *Agriculture*, a term applied to ſuch wheat and other crops as are ſpotted by a ſort of mildew in the ſtraw, &c. See Mildew.

Freckles, in *Medicine*, ſmall brown or duſky ſpots, which are ſprinkled on the ſkin, eſpecially of the face, neck, hands, and ſuch parts as are expoſed to the ſun and air. They are moſt frequent in women, and eſpecially in thoſe of fair complexion, with red or auburn hair. They occur in various degrees as to ſize and denſity, but are never productive of any inconvenience. In ſome perſons they appear only during the ſummer, and diſappear with the return of cold weather; but in others they are permanent. The Latins denominated them *lentigines*, from their fancied reſemblance to lentils; the Germans call them *ſommerſproſſen*, and *ſommerflecken*, from the appearance in hot weather; by the French they are termed *rouſſeurs*; and *roſſore* and *lentigine* by the Italians. The humoral phyſicians found an eaſy explanation of the origin of freckles, in the depoſition of the oily, or bilious portions of the fluids in the ſkin, in conſequence of the evaporation of the thinner parts, which the ſummer heat was ſuppoſed to occaſion. But as neither oil, nor bile, nor "fuliginous vapour" (as Turner ſuppoſes) exiſt in the blood, theſe hypotheſes are mere abſurdities. In truth, we are equally ignorant of the nature of theſe cutaneous ſpots, as of the means of removing them when formed. Various diſtilled waters, as of elder-flowers, bean-flowers, &c.; infuſions of theſe flowers in goat's milk, alum, the preparations of lead, &c. have been recommended by different writers, as efficacious in the removal of freckles; but we believe their remedial powers to be purely imaginary. As the freckles appear only on parts expoſed to the air and light, the moſt obvious means of preventing or removing them muſt conſiſt in excluding the operation of thoſe agents upon the ſkin as much as poſſible. See Sennert. Opera, lib. v. p. iii. § i. cap. iii. Turner on the Skin.

FREDDO, in *Geography*, a river of Sicily, in the valley of Demona, which runs into the ſea.—Alſo, a river of Calabria, which runs into the ſea. N. lat. 39° 18'. E. long. 16° 15'.

FREDEBURG, a town of Germany, in the kingdom of Weſtphalia; 52 miles E. of Cologne.

FREDEGAIRE, in *Biography*, the moſt ancient of the French hiſtorians, flouriſhed in the ſeventh century. Of his hiſtory nothing is known. He compoſed a chronicle in five books, containing a chronological hiſtory from the creation to the fourth year of Clovis II. which has been continued by other authors to the year 768. It is very defective as a hiſtory, but is indiſpenſible in the account of three of the early kings. Moreri.

FREDEGONDE, a woman famous in the early period of French hiſtory, was deſcended from an obſcure family in Picardy. She entered into the ſervice of Audouaire, firſt wife of Chilperic I., king of France, and procured her divorce. Chilperic then married Galſuintha, daughter of the Viſigoth king of Spain, who was ſoon after found dead in her bed. About the year 568 he raiſed Fredegonde to the throne. In this high ſituation ſhe uſed her power to the worſt purpoſes: ſhe cauſed Sigebert, brother of Chilperic, to be aſſaſſinated in the midſt of his army. She afterwards brought to a like end Merovèe, the ſon of Chilperic by his firſt wife. A venerable biſhop of Rouen was her next victim, whom ſhe cauſed to be ſtabbed at the altar. Reſolved to make the way clear for her own children, ſhe contrived the death of Clovis, younger brother of Merovèe, which was followed by that of their mother Audouaire. There ſeemed no end to her cruelty, till at length her temper was ſomewhat affected by the loſs of three of her own children by an epidemic diſtemper, and ſhe then perſuaded the king to repeal ſome oppreſſive impoſitions laid upon his ſubjects. In 584 Chilperic himſelf was aſſaſſinated by an unknown hand, but the ſuſpicion fell on Fredegonde, whoſe criminal paſſion for another perſon, the king is ſaid to have detected. Fredegonde being now driven from the throne, fled with her remaining ſon, Clotaire II., then an infant, and took refuge at the court of the king of Burgundy, whom ſhe found means to intereſt in her favour. An attempt was made by Childebert to poſſeſs himſelf of the eſtates of young Clotaire, but his mother raiſed troops, put herſelf at their head, gained a victory, and triumphed over her enemies. She died in 597, leaving the affairs of her ſon in good condition. Moreri.

FREDELAND, in *Geography*, a town of Pruſſia, in Pomerania; 60 miles S.S.W. of Dantzic.

FREDENSBORG, a town of Denmark, in the iſland of Zealand; 18 miles N. of Copenhagen. N. lat. 55° 59'. E. long. 12° 25'.

FREDENWALDE, a town of Brandenburg, in the Ucker

Ucker Mark; 40 miles N. of Berlin. N. lat. 53° 7'. E. long. 13° 50'.

FREDERIC I. ſurnamed *Barbaroſſa*, in *Biography*, emperor of Germany, born in 1121, was the ſon of Frederic duke of Swabia, and ſucceeded his uncle Conrad III. on the imperial throne in 1152. His enterpriſing and martial diſpoſition led him to aſſert all the prerogatives claimed by the German empire. Soon after he came to the crown he ſettled a diſpute between two rivals for the crown of Denmark, and obliged Sueno, the ſucceſsful one, to do him homage. To ſhew his independence on the pope, with whom he began to have diſputes, he repudiated, by his own authority, his wife Adelaide, on account of conſanguinity. The troubles of Italy called him into that country in 1155, where he received the ſubmiſſion of moſt of the Italian great lords and cities. At Pavia he was crowned king of Italy, and had an interview with pope Adrian IV. to whom he paid homage. He then re-eſtabliſhed the pontiff in Rome, whence he had been expelled by a tumult, received the imperial crown from his hands, and then returned to Germany, and called a diet at Beſançon. The pope's legates, who attended this meeting, gave ſo much offence by reading a letter from him, in which he pretended that he had conferred the empire upon Frederic by his own free grace, that they were driven out with ignominy and contempt, and the emperor publicly gave the lie to the pope's aſſertions. This diſpute was compromiſed, and Frederic reduced to obedience Boleſlaus, duke of Poland, who had aſſerted his independence. Having pacified Germany, he proceeded again into Italy with a powerful army. Here he invaded the republics of Lombardy with the arts of a ſtateſman, the valour of a ſoldier, and the cruelty of a tyrant. "The recent diſcovery of the pandects," ſays the hiſtorian, "had renewed a ſcience moſt favourable to deſpotiſm; and his venal advocates proclaimed the emperor the abſolute maſter of the lives and properties of his ſubjects." He every where arrogated the rights of unlimited ſovereignty, and carried fire and ſword through thoſe places which ventured upon oppoſition. On the death of Adrian IV. there was a violent ſchiſm with regard to a ſucceſſor, and the emperor was excommunicated by Alexander III. who had been choſen pope by the cardinals. Frederic in revenge made himſelf maſter of Milan in 1163, and gratified his reſentment by razing the city to the ground, ſparing nothing but the churches. Theſe ſevere examples put an end to all farther oppoſition in Lombardy, and he returned to Germany, and ſet out to meet Lewis the Young, king of France, at a council to be held for terminating the papal ſchiſm, but it proved ineffectual. He was obliged again to croſs the Alps to puniſh his enemies, and upon his return to Germany pope Alexander was eſcorted to Rome by the king of Sicily, and took poſſeſſion of his ſee. Frederic reviſited Rome, and the pope thought it prudent to eſcape in the habit of a pilgrim to Beneventum. The antipope was now ſeated in his chair, and he crowned the emperor with his empreſs Beatrice. His ſucceſs was of ſhort duration, for the plague made ſuch ravages in the army that he was obliged to make a rapid retreat. With the utmoſt difficulty he reached Alſace with the wreck of his army, while the confederates in Lombardy ſtrengthened themſelves, and pope Alexander received ſuccours from the Greek emperor Manuel. Frederic appeaſed the diſorders of Saxony, where the nobles had taken up arms againſt their duke, and procured the election of his eldeſt ſon Henry to the dignity of king of the Romans. He again marched into Italy, reduced ſeveral towns, till at length fortune ſeemed to turn againſt him, and he was totally defeated in a battle at Signano; and about the ſame time his ſon Henry was defeated in a ſea-fight with the Venetians, and taken priſoner. The cauſe of Frederic now in Italy was ſuch, that he propoſed an accommodation with pope Alexander. They had an interview at Venice in 1177. The emperor was very humble before his holineſs, who abſolved him from all eccleſiaſtical cenſures, and communicated with him. This reconciliation produced the treaty of Conſtance, in which Frederic confirmed the freedom of twenty-four cities with a reſervation of his rights as ſovereign. In 1183 the treaty of Placentia confirmed the agreement made between the emperor and the Lombard towns. Nevertheleſs, new troubles were perpetually ariſing from ſources frequently unexpected: twice on the emperor's rejecting the popes' Lucius III. and Urban III. the ſovereignty of the counteſs Matilda's eſtates, called St. Peter's patrimony. He ſeized the greater part of this property, and by the marriage of his ſon Henry with the heireſs of William king of Sicily, ſo far ſtrengthened his intereſt in Italy, that the popes, though they had many cauſes of complaint againſt him, were afraid to proceed to extremities. At length the news of the capture of Jeruſalem by Saladin ſuſpended domeſtic quarrels among the Chriſtians, and the emperor, as firſt prince of Chriſtendom, took the croſs in 1188, with his ſon Frederic, and a number of the principal nobles of Germany. Aſſembling an army of 160,000 men in the plains of Hungary, he proceeded to the territories of the Greek emperor, who did all in his power to impede their march, ſo that Frederic was compelled to act againſt him as an enemy, and to make his way by force. With a reduced army he reached the Turkiſh frontier, took the city of Iconium, croſſed mount Taurus, and was proceeding in the career of victory, when Frederic, tempted by the great heat of the climate to bathe in a river of Cilicia, was carried away by the current and drowned. The enterprize in which he had engaged would probably have proved fatal, even had he eſcaped this misfortune, for his ſon and the greateſt part of his army afterwards periſhed of a peſtilential diſeaſe before the walls of Acre. Frederic died in 1190 in the ſixty-ninth year of his age. Beſides the vigour and capacity which he diſplayed in action, Frederic poſſeſſed ſome literary talents, and drew up memoirs of his own life, which he gave to Otho the hiſtorian. Gibbon. Univ. Hiſt. Moreri.

FREDERIC II. grandſon of the preceding, and ſon of the emperor Henry VI. by Conſtance of Sicily, was born in 1194. He was created king of the Romans in his cradle, but the premature death of his father prevented his ſucceſſion at the firſt vacancy. He was educated with great care by his mother, and acquired the Greek, the Latin, German, French, and Turkiſh languages. He aſcended the throne when he was about eighteen years of age, in the full poſſeſſion of thoſe accompliſhments which are expected to give luſtre to a diadem, and to render a nation happy. His hereditary poſſeſſions were very conſiderable, including the kingdoms of Naples and Sicily, the dukedom of Swabia, and other German territories. When the emperor Otho was excommunicated by the pope, Frederic was declared emperor, and became peaceable poſſeſſor of the imperial throne by the retreat and death of Otho. He was ſolemnly crowned at Aix-la-Chapelle in 1215. As an acknowledgment of the favours which divine Providence had hitherto beſtowed upon him, he made a vow to go in perſon to the Holy Land. The firſt four years of his reign having been ſpent in arranging the affairs of the empire, and curbing the rebellious ſpirit of Otho's adherents, he made a progreſs into Italy in the ſummer 1220, and received the imperial crown from Honorius III. He alſo cauſed his ſon Henry to be declared king of the Romans, and promiſed upon oath that he would

lead an army into Aſia, at any time his holineſs ſhould appoint. He was, however, ſo tardy in the execution of his vow, that Honorius threatened to excommunicate him: a rupture enſued, which threatened very ſerious conſequences, for the emperor not only remonſtrated with the pope, but publiſhed a ſevere manifeſto for the juſtification of his own conduct, and ordered his troops to march to the frontiers of the eccleſiaſtical ſtate. Honorius now perceived the raſhneſs of his own conduct, apologized, and a reconciliation took place, in which Frederic agreed to marry Yolanda, daughter of the king of Jeruſalem; and promiſed to ſet out with an army in two years for the recovery of Paleſtine. Notwithſtanding theſe renewed engagements, Frederic ſtill heſitated to take the croſs: Honorius again remonſtrated, and a literary correſpondence commenced, in which he accuſed the emperor of ingratitude and cruelty to his father-in-law, who had ceded his title to the kingdom of Jeruſalem. On the death of Honorius, and the elevation of Gregory IX. to the apoſtolic chair, Frederic avowed his intention of performing his engagement, and actually ſet ſail, with a powerful armament; but about three days after he had put to ſea, a ſlight indiſpoſition ſerved as an excuſe for his return. The pope now without heſitation excommunicated him, and ſuch commotions enſued, that Frederic thought proper to ſet out immediately for the Holy Land, but as he did not carry with him the pope's abſolution, he was coldly received at Jeruſalem; the cruſaders peremptorily refuſed to acknowledge him as their chief, and he concluded a treaty with the Saracens. He then cauſed himſelf to be crowned at Jeruſalem, and returned to Naples with a title which has ſince been preſerved by the Sicilian monarchs. Frederic now employed himſelf in attempting to reduce the revolted cities in Lombardy; but while thus engaged, his ſon Henry, king of the Romans, formed a confederacy againſt him, which obliged him to viſit Germany. A diet was held at Mentz, in which his ſon was convicted of rebellion, and was in conſequence ſent to Sicily; but upon freſh conſpiracies being detected, he was made cloſe priſoner in the caſtle of Apulia, where he ſoon after died. He then invaded the dominions of the duke of Auſtria, his ſon's accomplice, took Vienna, where he founded the univerſity, and procured the election of his ſon Conrad as king of the Romans. After this he returned to Italy with a powerful army, gained a conſiderable victory over the Lombard league, and became ſo formidable, that the pope openly took part againſt him, and renewed his excommunication. A moſt fatal war ſucceeded, which ſpread through Italy, and in the courſe of which almoſt every town was ravaged by the hoſtile armies. Gregory died; but his ſucceſſor, pope Innocent IV., continued the quarrel, and excommunicated the emperor in 1245. The pope's party being triumphant, they elected a new king of the Romans; an attempt was made to poiſon the emperor, but it was rendered abortive by a timely diſcovery. At the ſiege of Parma, undertaken by Frederic, he met with a total defeat, which cauſed his party to be almoſt entirely diſperſed in the north of Italy. He was now obliged to retire to the kingdom of Naples, where he died of a fever in the fifty-fifth year of his age, and thirty-fourth of his reign. Frederic II. appears to have been a prince of great courage, genius, and fortitude; but his more ſplendid qualities were tarniſhed by ambition, violence, and an inordinate attachment to the fair ſex. He married ſix wives, of whom the laſt was daughter of John king of England. He was addicted to the follies of judicial aſtrology, and though he has been charged with maintaining atheiſtical tenets, yet as the charge was made through the medium of the popes, with whom he was perpetually at variance, it is ſcarcely to be relied on. He was unqueſtionably a patron of learning, and cauſed the works of Ariſtotle and others of the ancients to be tranſlated from the Greek and Arabic into Latin. He himſelf compoſed poems, and ſome proſe works, and he is ſaid to have had a ſhare in the famous treatiſe "De tribus Impoſtoribus." It was a fundamental maxim of his conduct, never to poſtpone any buſineſs till to-morrow which he could poſſibly perform in the current day. Moreri. Univ. Hiſt.

FREDERIC III., emperor, ſon of Erneſt, duke of Auſtria, ſucceeded his couſin Albert II. in the year 1440. He was now in his twenty-fifth year, and one of his firſt acts was to convoke a diet for the purpoſe of terminating the ſchiſms then ſubſiſting in the papal ſee, but as his propoſitions were totally diſregarded, he left the matter to the contending popes to ſettle as they pleaſed. In 1451 Frederic viſited Italy in order to receive the imperial crown from the pope. This ceremony was performed with due pomp, but did not enable him to recover any of the rights of the empire which had been torn from it by various uſurpers, and his viſit left a very unfavourable impreſſion of his talents on the minds of the Italians. An attempt was made to rouſe him to exertion when Conſtantinople was taken by the Turks, but he could not be prevailed on to make any efforts in the Chriſtian cauſe. He was engaged ſome time in domeſtic wars for the poſſeſſion of the duchy of Auſtria, which on the death of Albert he obtained. In 1468 he viſited Rome, held ſeveral conferences with the pope concerning means for reſiſting the progreſs of the Turks; but nothing of importance followed. Frederic was, however, very intent upon the aggrandizement of his family, and the marriage of his ſon Maximilian to the heireſs of the rich houſe of Burgundy, and thus had the good fortune to be the author of the greateſt acceſſion of dominion that his race ever acquired. From this period he repoſed upon Maximilian the chief weight of the government, who was ſoon after elected king of the Romans. Upon the death of Matthias he obtained from his ſon Ladiſlaus the reſtitution of Auſtria, and afterwards regained Tyrol from the duke of Bavaria; at length he quitted the reins of empire, and retired to Lentz, where he occupied himſelf in ſcientific ſtudies. He died at the age of ſeventy-nine years, in conſequence of an amputation of his leg. He was a prince of an agreeable air and majeſtic countenance: he was plain in his apparel, moderate in his paſſions, and ſo remarkably abſtemious, that his life is ſaid to have reſembled a continual faſt. From his natural averſion from war he was ſurnamed the "Pacific," yet the inconſtancy of his temper often prompted him to embark in quarrels. He was endowed with a remarkably tenacious memory, but was deſtitute of courage, reſolution, and generoſity. He had a favourite maxim to which he had perpetual recourſe, *viz.* "that the beſt remedy for irretrievable loſſes is oblivion." Moreri. Univer. Hiſt.

FREDERIC I., king of Denmark, was born in 1473, and ſucceeded to the throne on the abdication of his nephew Chriſtian II. At a general diet of the Danes, convoked for the purpoſe, he was declared king, and the ſtates of Norway likewiſe proclaimed him monarch with the uſual formalities. Being of an ambitious and aſpiring mind he was anxious for reuniting the three kingdoms, and for that purpoſe wrote to ſome of the principal nobility of Sweden; but Guſtavus Vaſa was capable of defending the crown that was firmly fixed on his head, and therefore Frederic readily gave up his claims, and formed a treaty of alliance with that monarch. The iſle of Gothland, ſeized by admiral Norby, was afterwards the object of contention between the two

crowns; but Frederic, by his vigour and policy, finally annexed it to his dominions. The progreſs of the reformation in the laſt reign had brought religious differences to a criſis in Denmark, and, 1527. Frederic openly declared in favour of Lutheraniſm: while, however, he gave the aſcendancy to that perſuaſion, he determined that every ſubject of his dominions ſhould be at liberty to embrace either the doctrines of Luther or of Rome; that no perſon ſhould be perſecuted or moleſted on account of his religion, and that the religious of all denominations ſhould be permitted to marry: in conſequence of this wiſe and truly liberal decree, the abbeys and cloiſters were deſerted, all auſterities diſregarded, and Lutheraniſm was every where publicly preached and embraced. The depoſed Chriſtian II. in 1531 made an attempt for the recovery of his crown, but being defeated in his object, he was obliged to ſurrender himſelf priſoner, and was committed to cloſe cuſtody by his uncle. Frederic I. died, after a reign of ten years, at the age of ſixty. His conduct obtained him the title of "Pacific," and contemporary hiſtorians juſtly praiſe the prudence and moderation of his government, which rendered his reign proſperous and happy. At his death the clergy, who had been offended at his innovations, were left in a ſtate of uncertainty, in conſequence of which the proteſtant religion gained ground and gathered ſtrength. Frederic left children by both his wives, one of whom was the daughter of the elector of Brandenburg, the other of the duke of Pomerania. Univer. Hiſt. Moreri.

FREDERIC II., king of Denmark, ſon of Chriſtian III., was born in 1534, and ſucceeded to the throne on the death of his father in 1558. The firſt years of his reign were paſſed in the din of war, with the people of Dithmarſh, who had made themſelves independent, but who, after a brave reſiſtance, were forced to ſubmit to the law of the conqueror: he next engaged in a conteſt with Eric king of Sweden, whoſe embaſſadors, as they were paſſing into Germany, he arreſted in violation of the ſafe conduct he had granted them. This war was commenced in 1563, and was carried on with mutual detriment, and the moſt cruel devaſtations of both countries, till the depoſition of Eric by his own ſubjects in 1568. Peace was then made, but upon terms ſo unfavourable to Sweden that war was renewed in 1569. The Hanſeatic towns, which were claimed by both parties, took an active part in the hoſtilities, and the city of Lubec embraced the occaſion of revenging itſelf on Sweden for the many reſtrictions impoſed upon it, and upon the commerce of the city. They concluded a treaty with the king of Denmark, and joined his fleet with a powerful ſquadron. After this, Frederic held the balance between thoſe commercial towns, and intereſted himſelf more than his predeceſſors in acquiring an influence over the affairs of Europe. He rendered commerce flouriſhing, reſpected the rights and property of his ſubjects, and obtained the eſteem and affection of his people. Frederic married the daughter of the duke of Mecklenburg, and thenceforth attended to the preſervation of peace, and promoted the proſperity of his dominions. He augmented the univerſity of Copenhagen, and was the active patron of learning and learned men, among whom was the celebrated aſtronomer Tycho Brahe. He died in 1588, leaving behind him a high character, as well among his own people as with neigbouring nations. So highly was he eſteemed by foreign princes, that queen Elizabeth ſent him the order of the garter, and James VI. king of Scotland, entered into a treaty with him for obtaining in marriage his daughter Anne. Univer. Hiſt. Moreri.

FREDERIC III., king of Denmark, born in 1609, was ſon of Chriſtian IV. and ſucceeded to the crown in the year 1648, but his authority as a monarch was greatly curtailed by the power which the great lords of his kingdom aſſumed. One of his firſt meaſures was a treaty with the Dutch, the friendſhip of whom he acquired by ſeizing in the port of Copenhagen a fleet of Engliſh merchant ſhips laden with naval ſtores; which ſtep, while it involved him with England, obtained for him a ſubſidy and league of alliance from Holland. In 1657 Frederic, ſtimulated by the Dutch, declared war againſt Sweden, but the warlike Charles Guſtavus ſoon repreſſed the progreſs of the Danes, and paſſing over the ice to Zealand, laid ſiege to Copenhagen. Notwithſtanding the courage and vigour of Frederic, he was compelled to make peace upon very diſadvantageous terms. War, however, ſoon broke out again, and Copenhagen was a ſecond time cloſely inveſted by ſea and land. The Swedes took the fortreſs of Cronenburg, and the capital was ſaved only by the arrival of the Dutch fleet. In this conteſt Frederic evinced a bravery not often paralleled: he was always prepared to act, and he perſonally watched over every meaſure which was to be adopted for the purpoſe of maturing the ſucceſſes, and reaping from them their full advantage. By his incitements, and by his own example, the citizens of Copenhagen became intrepid ſoldiers, bravely fought in ſmall boats againſt the ſhips of the beſiegers, and ruſhed forward through a tempeſt of flames. Their wives and children ſeconded their ardour, and the queen animated them by her preſence and example. That memorable ſiege furniſhed inſtances of almoſt every ſpecies of heroiſm. After Charles was compelled to retreat, Frederic rewarded the valour and fidelity of the citizens by well merited privileges. Peace was concluded in the year 1660: its terms were the reſtitution of all the Daniſh iſles of the Baltic, with the diſtrict of Drontheim, while Sweden retained the iſle of Rugen, and the provinces of Bleking, Halland, and Schonen. The moſt important event of Frederic's reign was the change of the conſtitution from an elective and limited, to an hereditary and abſolute monarchy. This was brought about by the diviſions between the different ſtates of the kingdom, and the hauteur and ſelfiſhneſs of the nobles, who would not conſent to take their ſhare with the commons of the public burthens. The king ſecretly fomented the diſcontents, till the commons, ſtimulated by the ill treatment of the nobles, reſolved, in conjunction with the clergy, to lay the liberties of the nation at the king's feet. Frederic gladly made uſe of the occaſion, and, by means of the army, overawed the nobles to a concurrence in the project. In this manner all the rights and privileges of the ſtates were ſolemnly ſurrendered, and the king and royal family received the homage of the different orders in a public theatre prepared for the purpoſe. This important revolution was effected without bloodſhed, and Frederic never abuſed the gift: he regulated the ſeveral parts of government, eſpecially the mode of ſucceſſion, and iſſued what has been denominated the "royal law." This has been conſidered ever ſince as the national code in all things pertaining to the ſucceſſion and the power of the monarch. No ſooner had he obtained poſſeſſion of abſolute authority, than he moderated that paſſion for glory which he had formerly betrayed. The remainder of his reign was ſpent in forming political alliances, and reſtoring proſperity to his country by the arts of peace. He applied himſelf to reſtore, by his own example, the ancient ſimplicity of dreſs and frugality at table; to re-eſtabliſh his finances; to encourage merit, induſtry, and commerce; to reward thoſe who had ſerved him with fidelity; to redreſs grievances; to protect the oppreſſed; to relieve the indigent; and to become the father of his ſubjects. The intimate connection between Holſtein and Sweden was the principal cauſe of his diſquiet;

diſquiet; and he was preparing to ſupport his cauſe by arms when he was carried off by a chronical diſorder in 1670. Univer. Hiſt. Moreri.

FREDERIC IV., king of Denmark, was born in 1671, and ſuccceded his father Chriſtian V. in 1699. He immediately made an attack upon the dominions of the duke of Holſtein, but was ſoon called back to defend Copenhagen from the attack of Charles, who began his wounderful career by a ſpirited invaſion of Zealand. Frederic ſued for and obtained peace on condition that he repaired all the wrongs he had done to the duke of Holſtein, and yielded him full ſovereignty of his dominions. Frederic was more ſucceſsful at ſea and land in the years 1714 and 1715, when they gained great advantages, drove the Swedes out of Norway, and took ſeveral places. In 1720 peace was concluded under the mediation of England, upon terms favourable to Frederic, who retained the duchy of Sleſwick. From that time he governed his dominions in peace, and attended to their internal proſperity. He died in 1730, leaving the character of an able prince, but too much addicted to enterprize, and too readily liſtening to the ſchemes of projectors. He is charged with having diſtributed thepublic treaſure with a too laviſh hand among his courtiers. Univer. Hiſt.

FREDERIC V., king of Denmark, was born in 1723, and ſucceeded his father Chriſtian VI. in 1746. On his acceſſion he formed the reſolution of diſcharging all the debts of the crown. The principal creditors of the ſtate, wiſhing to divert him from his purpoſes, offered to reduce the rate of intereſt rather than have their money paid. "The wealth," replied the monarch, "locked up in my coffers would be of no uſe to the public, but when I ſhall have repaid it, you will do me a pleaſure, and render me a ſervice, by lending thoſe ſums at a low intereſt to my ſubjects, who may thus be enabled to extend their commerce and ſupport their manufactures." He preſerved his dominions in peace, and promoted commerce and the manufactures, ſo as to make a large increaſe to the wealth of his people, and his own revenues. He eſtabliſhed a Greenland company; laid open to all his ſubjects the trade to the American colonies; encouraged agriculture, and the working of the mines, and made new roads. He was the zealous patron of the arts and ſciences: founded ſeveral academies and other places of inſtruction for the Laplanders; and inſtituted ſocieties for the improvement of painting, ſculpture, and architecture, and ſent a miſſion of learned men into the Levant for the purpoſe of making diſcoveries in natural hiſtory and antiquities. He died January 1766, and could conſole himſelf on his death-bed with the pleaſing and delightful reflection, that "he had never injured a ſingle individual, and had not a drop of blood to anſwer for." Frederic was twice married, firſt to Louiſa daughter of George II. of England, and ſecondly to Juliana Maria, daughter of the duke of Brunſwick Wolfenbuttle. Univer. Hiſt.

FREDERIC AUGUSTUS I., king of Poland and elector of Saxony, ſon of the elector John George III. by a daughter of Frederic III. king of Denmark, was born in 1670, and ſucceeded to the crown of Poland in 1697. For this high honour there were many candidates, but in a ſhort time the competition was confined to Frederic and the prince of Conti. As a preliminary ſtep he openly abjured the proteſtant religion, and by laviſhing the Saxon treaſures, he was able to counterbalance the art and eloquence of abbé de Polignac, the French negociator. On the day of election the nobles and others, to the number of a hundred thouſand men, aſſembled on the plain of Warſaw, each palatinate being divided into companies, and ranged under their proper banners, with all the electors on horſeback, armed with lances. The ſenators having taken their ſtations, each in front of his diviſion, commenced their harangues: and the cry of "long live Conti," was almoſt univerſal, till the palatine of Culm pronounced with a firm voice the word "Veto," which ſtopped the proceedings of the aſſembly, and the election was poſtponed to the enſuing day. Early in the morning both parties preſented themſelves nearly equal in ſtrength. A double election was made, and Poland was thrown into general diſorder by the efforts of the opponents. At length Frederic marched a German army into the country, and gained poſſeſſion of Cracow, where he was immediately crowned, and univerſally acknowledged as lawful king by the Poliſh nation. In ratifying the election of Frederic Auguſtus his own partizans limited the number of forces that he ſhould be allowed to introduce into Poland, and ſpecified the circumſtances which ſhould authorize him to require the aſſiſtance of his Saxon troops. In defiance, however, of theſe reſtrictions, he ſurrounded himſelf with Saxons, becauſe, as being his native ſubjects, he could place greater confidence in them than in the Poles; and to attach them the better to his own perſon, he loaded them with favours, and beſtowed upon them the moſt honourable and lucrative offices of the ſtate. The Saxons became extremely odious, and when the diet aſſembled, a demand was made that the Saxon troops ſhould be withdrawn. Frederic reſiſted, and was, as a conſequence, deprived of his right and title to the crown of Poland. This degradation was inflicted by Charles XII. of Sweden, who impoſed the moſt rigorous conditions on the depoſed monarch, and, beſides compelling him to acknowledge Staniſlaus as the legitimate ſovereign of the republic, and to renounce all right to the crown and dominions of Poland, required him to write a letter of congratulation to the new king, upon his acceſſion to the throne. Auguſtus complied, but by the ſtyle of his epiſtle, he evinced his regret, and the violence which he offered to his inclinations. The event of the battle of Pultowa determined Auguſtus to avow his intentions by a public declaration of breaking the treaty he had contracted with Charles XII. and of re-aſcending the throne of Poland, and he concluded with requeſting the aſſiſtance of all Chriſtian kings and princes. Staniſlaus, who ſaw himſelf abandoned by his friends, his protector a fugitive, and his rival ſupported by the moſt powerful monarch of the north, was no ſooner informed of the approach of Frederic, than he declared that as he had taken the ſceptre with no other view than the preſervation of liberty, he was now ready to reſtore it, provided that ſacrifice would promote the tranquillity and peace of the country. Frederic aſcended the throne without oppoſition. For ſome years his reign was diſquieted by jealouſies on the part of the Poles who could never be reconciled to the preſence of the Saxon troops: at length, however, the civil diviſions were terminated, and the remainder of the reign was paſſed in peace. Frederic died at the age of ſixty-three. He had for ſome years previouſly to his deceaſe reſided in his electoral ſtates, where he was much beloved. He introduced an improved code of laws, founded ſeveral profeſſorſhips, and a college for educating the nobility at Dreſden, and was the author of other uſeful and ſplendid eſtabliſhments. Though he had, as we have ſeen, conformed to the Romiſh religion, he protected the Poliſh proteſtants from perſecution. His conſort continued to profeſs the reformed religion till her death, and was, on that account, never crowned queen of Poland. Univer. Hiſt. Moreri.

FREDERIC AUGUSTUS II., king of Poland and elector of Saxony, ſon of the preceding, was born in 1696, and ſucceeded his father in 1733 to his electoral and hereditary dominions.

dominions. On the death of the firſt Frederic, the French party ſet up Staniſlaus Leſzinſky, but the Auſtrians and Ruſſians ſupporting the late monarch's ſon, Frederic Auguſtus, he was crowned king at Cracow in 1734, and after a ſhort conteſt was left in the quiet poſſeſſion of his crown. This reign is not ſignalized by many important events, but in the year 1745 the king of Pruſſia took poſſeſſion of his electoral dominions, though he was not able to retain them. He again occupied the ſame territory in 1756, and kept them till the peace of 1763. In the autumn of the ſame year Frederic Auguſtus died, leaving behind him ſeveral children, among whom was the dauphineſs of France, and mother to the unfortunate Lewis XVI. Frederic poſſeſſed many private virtues, but was not active and enterpriſing as a king. Univer. Hiſt. Moreri.

Frederic, king of Sweden, prince of Heſſe Caſſel, was born in 1676. He married for a ſecond wife the ſiſter of Charles XII. king of Sweden, who upon the deceaſe of her brother, in 1719, was elected by the ſtates his ſucceſſor, upon condition of great limitation of the royal authority. In the following year ſhe obtained the conſent of the ſtates to reſign the crown to her huſband, who accepted it with all thoſe ſtipulations which rendered it the moſt limited monarchy in Europe. The inſufficiency of his powers rendered him unable to reſiſt the invaſion of the Ruſſians in 1741, who pillaged the country, and did great injury to the iron and copper mines. On a ſubſequent war the ſuperiority of the Ruſſians was ſtill more manifeſt: the Swedes were routed at every encounter, great part of their army was made captive, and all Finland loſt. Frederic died, without poſterity, in 1751. Univer. Hiſt.

Frederic-William, elector of Brandenburg, ſurnamed the "Great Elector," ſon of the elector George-William, was born in 1620 at Berlin, and the ſucceſſion to hereditary eſtates fell to him in 1640. He was brought up to the profeſſion of arms, and ſerved in the camp of Frederic-Henry, prince of Orange. When he ſucceeded to his dominions, he found them almoſt ruined by the Swedes and other powers, who had ravaged them without mercy in the late adminiſtration. The commencement of his own government was marked with great prudence and wiſdom; he corrected abuſes of various kinds, and reſtored the finances to order. In 1642 he received the inveſtiture of Pruſſia from the king of Poland, and in the next year he made a truce with the Swedes, on the expreſs condition that they ſhould evacuate the greateſt part of his ſtates, ſo that in a ſhort time he recovered the whole of his dominions. To oppoſe or counteract the ambitious projects of Charles-Guſtavus, king of Sweden, he entered into an alliance with Holland, and was extremely deſirous of obtaining the friendſhip of Cromwell and Lewis XIV. In 1655 he concluded a treaty with the Swedes, whoſe army he joined in the invaſion of Poland, contributed very much to the victory gained near Warſaw, and obtained for his ſervices the entire ſovereignty of Pruſſia. In conſequence of a powerful league formed againſt the king of Sweden, the elector deſerted his party, and made peace with the Poles on the ſame condition reſpecting Pruſſia; he now exerted himſelf moſt vigorouſly in favour of his new allies, and the war in the north ſubſiſted, with various ſucceſs, till the death of Charles-Guſtavus in 1659, an event that was ſoon followed by a general peace which guaranteed Pruſſia to the elector. Some years of public peace gave the elector an opportunity of diſplaying his character as a promoter and patron of thoſe arts which render a nation great. Of this opportunity he took every advantage: he rebuilt the dilapidated towns and the ruined villages; converted foreſts and deſerts into cultivated fields; he facilitated commerce and navigation by canals, and other projects and eſtabliſhments calculated for that purpoſe. Nor was he leſs attentive to exterior concerns, and omitted no occaſion to ſecure and extend his territorial poſſeſſions. When the ambition of Lewis XIV. threatened Holland, the elector concluded a treaty with the United States, by which he engaged to furniſh them with an army of twenty thouſand men in caſe of an attack. Joined by the imperial troops, he began his march in 1672, but was ſtopped by marſhal Turenne, who took poſſeſſion of all his territories in Weſtphalia. At this moment a wretch offered to rid him of his formidable enemy by aſſaſſination, which he rejected with the utmoſt horror and indignation, and inſtantly ſent word to Turenne of his danger. Soon after this, prudential motives obtained the aſcendancy in his mind, and he made a ſeparate peace with France, by which he gained all his loſt provinces. He had in this treaty reſerved to himſelf the right of defending the empire if it ſhould be attacked, which he exerciſed in 1674 by joining the allies with a body of troops in Alſace. The French, to free themſelves from this enemy, inſtigated the Swedes to make a diverſion in their favour by invading the marches of Brandenburg; a meaſure that forced the elector back to the defence of his ſubjects, and in June 1675 he obtained a ſignal victory over a ſuperior Swediſh army. In another inſtance, he was ſummoned to defend Pruſſia againſt the ſame enemy; he marched in the midſt of winter, croſſed the gulf of Courland with his army on ſledges over the ice, ſurprized the Swedes in their quarters, and forced them to a precipitate retreat from Pruſſia, with the loſs of the greater part of their forces. He now ſuffered ſome ſerious reverſes from the French arms, and reluctantly agreed to the peace of St. Germain in 1679, by which he reſtored all his conqueſts upon the Swedes, and abandoned the king of Denmark; and in return the French evacuated the Weſtphalian dominions, and paid him a ſum of money. From this time we hear no more of Frederic as a warrior, but we ſee him in a more elevated character, attending to the improvement of his country, and to the augmentation of its happineſs; and the reputation he had acquired for wiſdom and equity cauſed him to be choſen mediator on various occaſions between contending ſovereigns. The revocation of the edict of Nantes gave him a valuable acceſſion of induſtrious ſubjects, who enriched his country with their arts and manufactures. A French colony was formed at Berlin, which flouriſhed extremely in conſequence of the privileges which he conferred upon it. Frederic died of the dropſy at the age of ſixty-eight, in the year 1688. He beheld the approaches of death with compoſure, and employed his laſt hours in anxious cares for the public good. In private life he was kind and generous, fond of ſociety, quick in his temper, but readily appeaſed. He is conſidered as the boaſt and glory of his houſe, and the chief founder of its greatneſs. Gen. Biog.

Frederic I., king of Pruſſia, was ſon of the preceding, and born at Konigſberg in 1657. The conſtitution of this prince was weak and ſickly, and his education greatly neglected; at one time the prejudices of his father ran ſo ſtrong againſt him, that he had determined to change the order of the ſucceſſion, and made a will, by which he deviſed all the acquiſitions of territory he had himſelf made to be divided among the children which he had by his ſecond wife, to the prejudice of the ſubject of this article. This diſpoſition was not allowed to take place, and Frederic ſucceeded to the whole inheritance in the year 1688. Naturally ambitious, but not poſſeſſing ſufficient vigour to raiſe himſelf above his neighbours, who were equally powerful with himſelf, Frederic attempted to ſupply this defect by the pomp of titles, and

and turned his thoughts to the acquiſition of the regal dignity; this was the great object of his ambition, and the miniſters who oppoſed the project as chimerical and frivolous were quickly diſgraced. In the war carried on reſpecting the Spaniſh ſucceſſion, he ventured to unfold his deſign, and made it a principal condition of his co-operation with the emperor, that he ſhould be recognized king of Pruſſia, and a treaty to this effect was concluded at Vienna in 1700. It was ſoon concurred in by the powers of the north and by England, and the coronation was performed in 1701, in memory of which event he inſtituted the order of the knights of the black eagle. At the ſolemnity, it was remarked that he put the crown on his own head, and it is certain that no monarch was ever leſs clogged with conditions on the part of the people. Hiſtorians have conſidered this ſtep as a maſterſtroke of policy, and that which raiſed the houſe of Brandenburg to its independence on that of Auſtria; but at the time when the piece was acting, it was generally believed that Frederic had ſolicited an honour which his power was inadequate to ſupport. Even his conſort, Sophia-Charlotta of Hanover, ſiſter of our George I., a woman no leſs diſtinguiſhed for her literary merit, than for the characteriſtic virtues of her ſex, was ſo little pleaſed with her elevation to the rank of queen, that ſhe declared ſhe felt extremely mortified to be forced to go to Pruſſia and act the part of a ſtage-queen in preſence of her Æſop, alluding to the deformity of Frederic; and to the celebrated Leibnitz ſhe wrote, "Do not imagine that I prefer this pageantry and pomp of crowns, which are here ſo much eſteemed, to the charms of philoſophical retirement." Frederic, now a king, diſplayed all the magnificence of which he was capable, and was profuſe to a degree, which his country was ill able to ſupport. He was, however, at the deſire of his queen, the inſtitutor of the Royal Academy of Sciences at Berlin, becauſe ſhe perſuaded him that it was a fit appendage to royalty to patronize the ſciences. When Charles XII. of Sweden became formidable by his victories, Frederic obtained a neutrality for Pruſſia: but in the ſucceſſion war, his troops ſerved againſt France, and he even declared war againſt Lewis XIV. In 1705 his queen Sophia Charlotta died with the utmoſt calmneſs, recollection and compoſure: "Weep not for me," ſaid the dying queen to one of her attendants, "I am now going to ſatisfy my curioſity reſpecting the principles of things which even Leibnitz has never been able to explain to me; and I am preparing for the king my huſband the exhibition of a funeral pomp, in which he will have full opportunity of diſplaying all his oſtentation and magnificence." In truth ſhe was not miſtaken; the king honoured her with a ſplendid funeral, and in the pomp he compenſated, in his own mind, for the loſs of a wife whoſe death could not be ſufficiently deplored, and in 1709 he took another, which was his third. In the enſuing year his Pruſſian dominions ſuffered greatly from a peſtilential diſorder, which carried off multitudes of his ſubjects, but the court attempted no means of relief, being too much abſorbed in vain and oſtentatious expences. Amidſt the ſubſequent diſturbances of the north, Frederic employed his efforts to reconcile the different parties, and preſerve his own dominions in peace. He died in 1713. "He was," ſays his royal deſcendant "magnificent and generous; but at what price did he purchaſe the pleaſure of gratifying his paſſions! He trafficked in the blood of his people with the Engliſh and the Dutch, like the wandering Tartars, who ſell their herds to the butchers of Podolia." It has been ſaid of him that "he was great in little matters, and miſerably little in great concerns." He has, however, the misfortune to hold his ſtation in hiſtory, between a father and a ſon, by whoſe great and tranſcendant abilities his merit is eclipſed. Univer. Hiſt.

Frederic William, king of Pruſſia, with both names is conſidered as the I^st., but as "Frederic" only, he is the II^d. of that name. He was ſon of the preceding by Sophia Charlotta, and born in 1688. At an early age he diſplayed a paſſion for military exerciſes, and highly diſtinguiſhed himſelf in the allied army againſt the French. In 1706 he married the princeſs Sophia Dorothea, daughter of the elector of Hanover, afterward king George I. of England. On the death of his father in 1713 he ſucceeded to the throne, and exhibited a character in every reſpect the reverſe of that already delineated. He made great reductions, ſacrifices as they would be termed by little minds, in all the eſtabliſhments of royal pomp, and applied his whole attention to render his country great, by maintaining a full treaſury and a powerful army. In his own perſon he was extremely plain, and in his manners ſimple and eaſy of acceſs. He aboliſhed all uſeleſs expenditures, retained but few perſons about himſelf, and reduced his private expences to a very moderate ſum. He was accuſtomed to ſay, "that a prince ought to ſpare not only the blood, but the property of his ſubjects;" and in this reſpect he might be regarded as a philoſopher on the throne; and the frugality which he exerciſed was worthy the character of an ancient Roman in the beſt age of the republic. By this moderation, and by his reforms in the finances and expenditure, he was enabled to keep up a great military eſtabliſhment, and he was the founder of that exact diſcipline and regularity for which the Pruſſian troops have been ſo much admired. He was remarkably deſirous of tall men for his army, and he indulged the paſſion to a degree of ridiculous extravagance. He had a regiment compoſed ſolely of giants, whom he picked up from all the neighbouring countries at a vaſt expence, and without any regard to the means by which they might be obtained: he ſent to purchaſe them from the extremities of Europe to the borders of Aſia: many of them were entrapped into his ſervice, and others involved in quarrels, for the ſake of having a pretence to their future ſervices. He was equally attentive to propagate the breed by matching them with the talleſt women in his dominions, who were compelled to the union. Nothing, indeed, could be more deſpotic than his whole military ſyſtem. In other reſpects he ſtudied the happineſs of his ſubjects, and the proſperity of the ſtates. Soon after his acceſſion he was recognized as king of Pruſſia in a treaty with France. Tired of the humiliations which his father had frequently ſuffered from the Swedes and Ruſſians, who marched their troops through his dominions with impunity, he determined to protect his ſubjects from the conſequences of any future rupture that might happen among his neighbours. The mind of the monarch was excited to the formation of his plans by the obſervations which he had heard, when young, from two Engliſh generals, one of whom boldly aſſerted that the king of Pruſſia could not maintain a force of fifteen thouſand men without the aid of foreign ſubſidies, while the other contended that he was able to ſupport twenty thouſand. The prince, though a ſtripling, ſaid with a degree of warmth that ſurprized the diſputants, "The king, my father, is able to maintain a force of thirty thouſand men, if he thinks proper." In the firſt year of his own reign he contrived almoſt to double that number without the help of foreign ſubſidies. Notwithſtanding the peace of Utrecht, war continued in the north between Charles XII. and the emperor of Ruſſia, and the kings of Poland and Denmark; into this Frederic did not wiſh to enter, but was compelled by an attack of Charles, who made five hundred of the Pruſſian

Pruſſian ſubjects priſoners of war. Frederic, now affected by the inſult, exclaimed, "What! ſhall a prince whom I ſo much eſteem compel me to become his enemy?" He immediately declared war, put himſelf at the head of his army, and joined the Saxons and Danes with twenty thouſand troops. After compelling the king of Sweden to abandon his territories, and to ſeek refuge in a foreign land, the conquerors divided among them the ſpoils of the conquered. Nevertheleſs, when Frederic heard of the news of the premature death of Charles (ſee CHARLES XII.) he ſhed tears, and did juſtice to the noble qualities of that prince, whoſe enemy he had moſt reluctantly become. After this, Frederic interfered with effect in favour of the proteſtants of ſome neighbouring countries, who were oppreſſed and perſecuted by their catholic ſovereigns. Frederic liberally rewarded the induſtry and ingenuity of the introducers of new arts; and many of the richeſt fabrics in the country owe their eſtabliſhment to him; but his patronage was entirely confined to what he deemed uſeful. Being void of ſcience and ornamental literature, and not knowing how they could be connected with the public proſperity, he regarded them with contempt, and treated their profeſſors with every ſpecies of diſcouragement. Poetry and abſtract philoſophy were equally his averſion. He baniſhed a man of letters for ſome Latin verſes over the gate of the palace, and expelled the celebrated Wolf for his metaphyſical opinions; and his eldeſt ſon, the prince royal, who had acquired a great partiality for polite literature and muſic, was ſo continually thwarted by the king, and rendered ſo extremely uncomfortable, that he took the reſolution of privately quitting the Pruſſian dominions for France or England. His deſign was diſcovered, its execution prevented, and the prince himſelf, with two young officers who were his confidants, were proceeded againſt as criminals. One of them had the good fortune to eſcape; but the other, a very amiable youth, was condemned to death by the ſtern and ſavage monarch, who forced his own ſon to be a ſpectator of the bloody deed. The prince himſelf very narrowly eſcaped a like puniſhment, but after ſeveral months' cloſe impriſonment he was ſet at liberty. Such a father, however, could not expect to inſpire in the heart of his ſon any other feelings than thoſe of horror, and the more ſo, becauſe about the ſame time he cauſed a young woman, ſuſpected only of an intrigue with the prince, to be publicly whipped through the ſtreets of Berlin. In every inſtance he was moſt rigorous in his puniſhments, and always ſhewed an inclination to aggravate rather than mitigate them. In the year 1734 Frederic-William fell into a bad ſtate of health, which increaſed the natural violence and irritability of his temper: to his phyſicians he even behaved with great brutality, though he held the celebrated Hoffman in ſome reſpect. At length he became tranquil and reſigned to his approaching fate, and died in the year 1740, and in the fifty-ſecond year of his age. At this time he probably relented and was grieved for his conduct towards his ſon, with whom he held many conferences previouſly to his deceaſe, teſtifying the greateſt regard for him, and in his arms he at length expired. Frederic-William left behind him an army of ſixty-ſix thouſand men, and an abundant and increaſing treaſury. All his affairs were in the greateſt order and regularity, and to the labours and pre-eminent wiſdom of this prince we are to look for the ſources of that proſperity and ſucceſs, which diſtinguiſhed the houſe of Brandenburgh till it was humbled by the talents of the preſent emperor of France, before whom the monarchs of Europe have appeared almoſt as nothing. Univ. Hiſt.

FREDERIC III, king of Pruſſia, generally denominated "The Great," was ſon of the preceding, and born at Berlin January 24, 1712. In the progreſs of his education he enjoyed very few advantages, for his father wiſhed to make him a complete ſoldier at the expence of every literary accompliſhment. As, however, he grew towards manhood, he diſplayed a taſte for the liberal arts, which, as we have ſeen, had nearly coſt him his life. This taſte was formed by the peruſal of French books which were put into his hands, and to which all his reading was confined. The tyranny which he experienced from his father was the means of turning his attention to ſcientific purſuits, and being unwilling to incur the king's diſpleaſure, from which he had already ſuffered ſo much, he retired in a meaſure from the world, and purſued his ſtudies in private; and to the amuſing branches of literature he added the ſolid attainments of the mathematics and philoſophy. In 1733 he married, by order of the king his father, Elizabeth-Chriſtiana, a princeſs of the houſe of Brunſwic-Wolfenbuttle; but it is certain, though obliged to marry, that he never cohabited with her, though it is generally ſuppoſed that it was not mere perſonal diſlike that prevented a cloſer union, but that ſome phyſical cauſe exiſted with reſpect to the prince. Frederic had not long been ſeated on the throne before he manifeſted an inclination to uſe his utmoſt efforts for enlarging his dominions. His father's ſuccour to the imperial army in 1734 had given him an opportunity of converſing with prince Eugene on military affairs, and a viſit in the following year to Staniſlaus, king of Poland, then a fugitive at Konigſberg, gratified him with the friendſhip of an amiable and lettered ſovereign. His connection with literary characters was extended, and in the year 1736 he began a correſpondence with the celebrated Voltaire, who contributed ſo much in forming his opinions and his taſte, and who impreſſed him with that ſpirit of toleration which diſtinguiſhed the whole reign of Frederic. And notwithſtanding the obliquity of Voltaire's mind with reſpect to religion, he did not fail to inculcate upon his pupil the duty of promoting as much as poſſible the happineſs of the people committed to his charge, by the practice of juſtice and humanity, and by the encouragement of the arts of peace. (See VOLTAIRE.) Many perſons of literary diſtinction formed a part of the prince's court, which has been repreſented as the ſeat of the muſes and the graces; and the character of Frederic at this period was that of one of the moſt polite and faſcinating young men in Germany. He aſcended the throne in May 1740, and immediately obtained the poſſeſſion of all that popularity which uſually waits upon a young ſovereign who ſucceeds to an unamiable predeceſſor. The firſt act of the new king was to diſband the regiment of giants; at the ſame time he inſtituted an order "of Merit," which admitted perſons of real worth in arms or arts, without diſtinction of birth or country. He invited many learned foreigners to ſettle in his dominions; he recalled Wolf, and appointed him to be the head of the univerſity at Halle. Maupertuis and Algarotti accepted his invitation, and took up their reſidence with him. While he was a prince only he wrote, and afterwards publiſhed, his "Anti-Machiavel," which was intended to refute the baſe maxims of that author relative to the morals of ſovereigns: but "it was unfortunate," ſays his biographer, "that one of his firſt practical comments upon it ſhould be the ſeizure, by military force, of ſome diſtricts in the biſhopric of Liege, upon which he had an obſolete claim, and which he afterwards readily reſtored for a ſum of money." This was not the only inſtance, by many, in which Frederic, by his own acts, ſhewed how little he regarded the common rules of morality, when they ſtood in the way of his wiſhes as king. On the death of the em-

peror Charles VI. which occurred in October 1740, a vaſt inheritance had come to his daughter, which, though guaranteed by almoſt all the powers of Europe, was regarded by many of the ſovereigns, among whom was Frederic, as a tempting prey. At the time he did not fully avow his motives, but declared that he had thought proper to cauſe his troops to enter Sileſia, in order to cover it from being invaded or attacked, and the rather becauſe the duchy ſerved as a barrier to his dominions, whither the flames of war, which now threatened Europe, might be extended, and expoſe them to danger. He has, however, ſince that period, in an account of himſelf, honeſtly declared that he was probably induced to take this meaſure becauſe he had "an army quite fit to march, a treaſury ready prepared, and, perhaps, the ambition of acquiring renown." He aſſembled a choice army of 30,000 men, at the head of which he put himſelf, though ſcarcely recovered from an intermittent fever, in the middle of December, beginning his march the morning after a grand maſked ball. A feeling of propriety induced him to eraſe the word *Deo* from the motto of his ſtandard, in which it was joined with *pro Patria*, and he cauſed the appropriate Roman eagle to be borne before his regiment of guards; and it is ſaid, that on mounting his horſe, and taking leave of the marquis de Beauveau, the French miniſter, he obſerved, "I believe I am going to play your game for you; if the aces turn up, we will divide." He penetrated Sileſia with little oppoſition, and levied heavy contributions on the inhabitants, under pretence of ſubſiſting his troops. The Sileſians, not poſſeſſing a force ſufficient to oppoſe the Pruſſians, were compelled to ſubmit. He ſoon, however, found his progreſs arreſted by an Auſtrian army, which engaged him at Molwitz, and in this engagement he was himſelf carried away in the rout of his cavalry, and his behaviour at the inſtant ſubjected his courage to ſome imputations, which, however, his future heroiſm abundantly obliterated. The Pruſſians were finally victorious in this combat, and the king took poſſeſſion of Breſlaw, the capital of the province, where he received the homage of the ſtates. He returned in triumph to Berlin towards the cloſe of the year, having firſt ſent a detachment of troops to aid the French and elector of Bavaria in their invaſions of Bohemia and Moravia. At length he made a ſeparate treaty at Breſlaw with the queen of Hungary, who was glad to free herſelf from ſo dangerous an enemy by ceding to him all Sileſia, except three duchies, and alſo the principality of Glatz in Bohemia. Thus was Frederic's firſt attempt crowned with complete ſucceſs. He employed the interval of peace in improving the internal government of his dominions, and forming eſtabliſhments calculated to promote their proſperity. He renovated the Academy of Sciences at Berlin, gave it a more enlarged plan, and provided for it an acceſſion of new members. In the year 1744 a war broke out between France and England, and the latter power was ſuppoſed to have entered into a defenſive alliance with Saxony and Auſtria, which Frederic thought might become offenſive againſt Pruſſia, and as he thought it was his intereſt to depreſs Auſtria, ſo he reſolved to effect it. The refuſal of the queen of Hungary to concur in the election of Charles VII. to the empire, was the immediate pretext for hoſtilities, and in Auguſt 1744 Frederic marched with an army of 80,000 men into Bohemia, and laid ſiege to Prague, which ſurrendered after a very ſevere bombardment. Notwithſtanding this ſucceſs, the campaign was ſo little to his mind that he forbade all perſons for ever from mentioning it in his preſence. In the following ſpring he returned to the ſcene of action, and obtained over his opponent, prince Charles of Lorraine, a moſt deciſive victory. While he was purſuing his ſucceſſes in Sileſia, his general, prince Anhalt, entered Saxony, and gave a very ſignal defeat to the Saxon army at Keſſeldorff. The king then joined him and proceeded to Dreſden, which immediately ſurrendered. He entered that capital and laid it under very heavy contributions: a treaty of peace was, however, concluded between the kings of Poland and Pruſſia, in which Vienna was included. The queen of Hungary was admitted as a party in the treaty of Dreſden, and confirmed the ceſſion of Sileſia according to the terms of the peace of Breſlaw, while Frederic agreed to acknowledge her huſband, the duke of Tuſcany, for emperor. After the terms of this peace were ſettled the Pruſſian troops evacuated Saxony, and Frederic returned to Berlin, where he was received by his ſubjects with the loudeſt acclamations.

The king now employed himſelf in improving his ſtates and in reforming the judicial proceedings, which he hoped not only to ſimplify, but to render uniform throughout all the different parts of his dominions. For this purpoſe he wrote and publiſhed "The Frederician Code: or a body of Law for the dominions of the king of Pruſſia, founded on reaſon and the conſtitution of the country." By this code torture, for the purpoſe of forcing confeſſion, was aboliſhed: the number of capital crimes greatly diminiſhed; and the rites of the catholic religion were tolerated. Frederic, about this period, appeared as the author of "Memoires pour ſervir à l'hiſtoire de la Maiſon de Brandebourg." This contains a conciſe account of his electoral and royal houſe, written in a good ſtyle, and with apparent impartiality. His reflections are often juſt and philoſophical; but he has occaſionally given way to his prejudices, and miſrepreſents incidental matters of fact; nevertheleſs, in the dedication of this work to the prince royal of Pruſſia, he ſays, "I have treated the ſubject with freedom and impartiality, ſo as to exhibit the princes of your houſe in real colours. The ſame pen, which has drawn the civil and military virtues of the great elector, has glanced at the foibles of the firſt king of Pruſſia, and thoſe paſſions, which, in the order of providence, contributed afterwards to raiſe this houſe to its preſent pitch of grandeur. I have diveſted myſelf of all manner of prejudice, and conſidered princes, kings, and relations only as ordinary men. Far from being biaſſed by the weight of power, or from idolizing my anceſtors, I have freely condemned their vices, becauſe vice ſhould find no patronage on the throne. I have praiſed virtue wherever I have found it, but, at the ſame time, have guarded againſt that enthuſiaſm which it naturally inſpires; to the end that nothing but truth, in her plain and native dreſs, ſhould reign throughout this hiſtory." His next publication was a "Poem on the Art of War," in ſix books, which is his largeſt poetical production, and which may rank among the moſt ſplendid and beſt planned didactic works in verſe. In this work he has celebrated the talents and courage of many ancient and modern generals; has beſtowed the higheſt encomiums on prince Eugene, and referred to the battle of Blenheim, yet he has never once mentioned the name, nor hinted at the glory of our illuſtrious countryman the duke of Marlborough. (See CHURCHILL.) "It is not to be ſuppoſed," ſays a contemporary writer, "that this ſilence with reſpect to the duke proceeded from invidious motives: we rather think that his Pruſſian majeſty conſidered *him* as a general who underſtood *only a part of his profeſſion*, having never given any proof of his ſkill *in conducting a retreat!!*" To this cutting and ſarcaſtic obſervation Frederic fairly expoſed himſelf by his want of candour. The compoſition of theſe and other literary pieces, his various ſtudies and amuſements, and the journeys which he undertook to different parts of his dominions, oc-

cupied all the leiſure he could command from thoſe royal duties which he always performed with the greateſt punctuality. His hours of relaxation were devoted to muſic: he indulged his taſte for the fine arts in decorating palaces, and erected ſplendid edifices at Berlin and Potzdam, which during his reign became equal, in their exterior, to the fineſt places in Europe. Frederic thought it due to his character and conſequence to inſiſt upon the right of free navigation for his ſubjects, without moleſtation from the contending fleets of other nations, and is regarded as the original author of the ſyſtem of armed neutrality, which has ſince produced ſo many important events.

At the commencement of the war in 1755 between England and France, the former made a treaty with the king of Pruſſia, which produced an alliance between France, Auſtria, and Ruſſia. Thus the whole political ſyſtem of the continent was changed: the ſeeds of a new war were plentifully ſcattered, and they ſoon ripened into events more extraordinary and intereſting than Europe had for a long time witneſſed. The ſeven years' war began in 1756 with the march of the king of Pruſſia, who was fully apprized of the confederacy which had been formed againſt him, in caſe of his giving riſe to a new war. He nevertheleſs demanded of the empreſs-queen the intention of certain armaments and warlike preparations which were making in her dominions, and whether they did not immediately concern him. Her anſwer was not ſo explicit as Frederic wiſhed, and he inſtantly commenced hoſtilities, and involved himſelf in a long and hazardous war, in the courſe of which he acquired a high degree of military fame, but which occaſioned, what is little regarded by continental ſovereigns, a miſerable effuſion of human blood, and was productive of much calamity to the Pruſſian dominions, as well as to the neighbouring countries. Frederic demanded a paſſage for his army through the electorate of Saxony, and did not wait for permiſſion to enter the country. The king of Poland, the elector, who had already experienced his power, aſſembled his troops at the ſtrong camp of Pirna, and repaired thither in perſon, leaving his queen at Dreſden. Frederic, who by the treachery of a Saxon ſecretary had been informed of the king's negociations with his enemies, thought himſelf juſtified in ſeizing to his own uſe all the public revenues of Saxony, and breaking open the ſecret cabinet in the royal apartments, notwithſtanding the perſonal efforts of the queen to prevent him. He next aſſumed the entire government of the electoral dominions, diſmiſſed the Saxon council and miniſters of ſtate, obtained poſſeſſion of the camp of Pirna, and compelled the common men of the Saxon army to enter among his own troops. At the beginning of 1757 the enemies of Frederic were aſſembling forces againſt him on all ſides, and every method adopted to excite a general abhorrence of his conduct, and he was put under the ban, or curſe of the empire, with all the cuſtomary formalities. The king, though menaced, was undiſmayed, and determined to carry war into the enemies' country: he advanced with four ſeparate bodies into Bohemia, which he united under his command, and on the 5th of May he fought the battle of Prague, which proved very bloody, but at length terminated in favour of the Pruſſians. The Auſtrians were obliged to take ſhelter in the city, which Frederic immediately inveſted, but, after committing terrible havock among the inhabitants and army, he was forced, by the great marſhal Daun, to raiſe the ſiege, and retreat in the beſt manner he was able. The king's affairs were now in an extremely critical ſituation: he was hemmed in on all quarters, and no activity and reſolution ſhort of what he poſſeſſed could have extricated him; nevertheleſs, at the cloſe of the year he ſaw himſelf victorious, and freed from the enemies which had ſo cloſely preſſed him. The ſplendour of the king of Pruſſia's actions had rendered him the object of general admiration: in England he was regarded as the proteſtant hero fighting for the cauſe of religion and liberty, and a ſubſidiary treaty was concluded by which England engaged to pay a ſum of ſix hundred and ſeventy thouſand pounds ſterling to the king of Pruſſia, for which he was bound to no ſpecific ſervices, but only to keep up his forces, and act for the common cauſe. In the campaign of 1758 the king penetrated into Moravia, and laid ſiege to Olmutz, which was ſaved by Daun: thence he was called to oppoſe the Ruſſians, and fought them at Zorndorff, and after a moſt obſtinate combat gave them a terrible defeat. To a ſimilar diſaſter he was himſelf expoſed at Dreſden. On the 12th of Auguſt in the following year the moſt deſtructive and horrible battle of Cunnerſdorff was fought. At firſt the king made ſure of ſucceſs, and announced his expectations in a billet to the queen; but having commenced a ſecond attack, the fortune of the day turned ſo completely againſt him, that he diſpatched a ſecond note ſaying, "Remove from Berlin with the royal family: Let the archives be carried to Potzdam. The town may make conditions with the enemy." Berlin however did not fall, and by the high military ſkill and great preſence of mind of the king, he repaired his own loſſes, and completely awed his enemies.

Though Frederic had exhibited the greateſt talents and moſt conſummate proweſs; though he had obtained the moſt ſplendid victories, and made exertions ſo extraordinary, that to common and ſuperficial minds they appeared the effect of miraculous interpoſitions rather than the ordinary courſe of events, yet he became ſenſible that the longer hoſtilities continued the more difficulties increaſed. His army was not compoſed of the ſame troops as thoſe with which he commenced hoſtilities, he had loſt vaſt numbers of men, not only in action, but by diſeaſes, by the rigour of the ſeaſons, and by perpetual hardſhips and fatigues. He was therefore, in the year 1761, induced to act chiefly on the defenſive. An event now took place, which was highly favourable to the affairs of the king of Pruſſia. This was the death of the empreſs of Ruſſia, with whoſe ſucceſſor the emperor Peter III. he inſtantly formed a treaty of alliance. This was followed by a peace with Sweden, and though the dethronement and death of Peter deprived him of the aid of Ruſſia, yet his ſucceſſor Catharine II. obſerved a neutrality in the remaining conteſt. In 1763, a treaty of peace was concluded, called the peace of Hubertſburg, from the caſtle of that name, in which the articles were drawn up and ſigned. This treaty was formed on the baſis of thoſe of Breſlaw and Berlin, and confirmed to Frederic his former Sileſian acquiſitions. The empreſs-queen, and the king of Pruſſia, renounced all claims upon each other's territories, and the only compliance made by the latter was a promiſe to vote for electing the archduke Joſeph king of the Romans. The electoral king of Poland was at the ſame time reſtored to his waſted dominions without any compenſation. Thus terminated what has uſually been called the ſeven years' war, between the Pruſſian monarch and the great and powerful princes with whom he was engaged in hoſtilities. It was one of the moſt ſanguinary conteſts that ever deſolated the globe, and though the military fame acquired by Frederic was very great, yet it muſt be conſidered as a trifling compenſation to his ſubjects, for the evils and calamities that they had ſuffered, and for the vaſt effuſion of human blood which had been produced by his ambition, and by that jealouſy which his numerous ſtanding army, and his conduct towards his neighbours had naturally and univerſally

inſpired. Peace being eſtabliſhed, Frederic returned to his capital, from which he had been abſent more than ſix years. The king, for ſome time ſubſequent to this period, cultivated the arts of peace, without neglecting thoſe of war. He concurred, in 1764, in exerting his intereſt to promote the election of count Staniſlaus Poniatowſki to the throne of Poland, in the room of Auguſtus III. who died ſoon after his reſtoration to his electoral dominions. Frederic received a viſit from the emperor of Germany, in the year 1769, at Neiſs in Sileſia, where they treated each other in a cordial and friendly manner; and, after ſpending two days in each other's company, parted with the ſtrongeſt profeſſions of mutual regard, eſteem, and confidence. They dined together in company with ſome general officers, among whom was the celebrated Laudohn, who had greatly diſtinguiſhed himſelf againſt the king of Pruſſia in the late war, and who was going to place himſelf at the lower end of the table, but Frederic exclaimed "I muſt beg the favour of general Laudohn to come and ſit by me, for I can aſſure him I had rather have him on my ſide, than oppoſite to me." Although the king kept up an army of two hundred thouſand men, fully equipped and diſciplined, yet he was extremely attentive to his treaſury, and was in every reſpect a good public economiſt. He had, however, recourſe to the ſcandalous and villainous meaſure of debaſing the coin which he iſſued from the mint, and then actually refuſed to take it in impoſts at its nominal value. He patronized many ſchemes for the promotion of manufactures and commerce, but was ignorant of the true ſpirit of trade. He violated the privileges of the free city of Dantzic, and practiſed, without heſitation or ſhame, the moſt wicked extortions. He planned the partition of Poland, and received for his ſhare of the booty Weſtern Pruſſia, the moſt commercial, though the ſmalleſt portion of the firſt diviſion. Previouſly to this he had, without remorſe, committed great exactions in the Poliſh territories, from which he had carried off the inhabitants in order to people the uncultivated parts of his own dominions. On ſome diſtricts he had impoſed a very ſingular tax, that of a proportion of their marriageable young women, each provided with a dowry, who were thus torn away from their country and friends, to be ſettled among ſtrangers, and often coupled with beings little better than barbarians. After he had taken poſſeſſion of that part of Poland, which the royal robbers had aſſigned to Pruſſia, he impoſed a variety of new and arbitrary regulations on the inhabitants of the uſurped provinces; and the Jews were obliged, by the ſevere treatment they experienced, to quit the diſtricts that had been ſeized by Auſtria and Pruſſia, and to retire into the provinces allotted to Ruſſia. To the Jeſuits, in other parts of his dominions, Frederic was more favourable, and though the pope had aboliſhed the order, he afforded them, as men of talents and real learning, an aſylum in the Pruſſian territories. One of the moſt important of the remaining public events of Frederic's life, was that which related to the project of diſmembering the electorate of Bavaria, by the court of Vienna. On this occaſion Frederic was the aſſertor of the liberty and independence of the Germanic body, and the oppoſer of lawleſs ambition: he took the field in perſon in 1778, with a powerful army, and was oppoſed by the emperor Joſeph and Laudohn, with an equal force. No action however enſued, and, in 1779, a treaty was entered into, which produced an abandonment of the deſigns of the Auſtrian court. In 1785, a plan was formed by the emperor for exchanging, with the elector-palatine, the low countries for Bavaria, which the king of Pruſſia defeated, by propoſing a confederation for maintaining the indiviſibility of the empire, and the laws of the Germanic conſtitution, which was immediately joined by ſeveral of the principal members of the empire. About this period the Pruſſian court remonſtrated with the ſtates of the United Provinces concerning the limitations of the power of the ſtadtholder, which were then in agitation. The Pruſſian miniſter preſented a memorial to the States-general, in which he requeſted, in the name of his maſter Frederic, that they would take ſuch meaſures as might effectually put a ſtop to the perſecutions that were then carried on againſt the ſtadtholder, and that they would maintain him in the enjoyment of thoſe prerogatives, which, it was ſaid, were the rightful attributes of his perſon and family. In 1786, a treaty of amity and commerce was concluded between Pruſſia and the United States of America, which was a model of liberal policy reſpecting the rights of two independent nations both in peace and in war.

Frederic, as he advanced in years, became milder and more humane, more attentive to the real welfare of his ſubjects, and more diſpoſed to prefer the uſeful to the ſplendid. His exertions in promoting agriculture, manufactures, and thoſe arts of life by which the lower and middle ranks of life are rendered comfortable and flouriſhing, were unrivalled by thoſe of any ſovereign of his time, and the increaſe of population and commerce in the Pruſſian dominions during the latter part of Frederic's reign, is a ſubſtantial evidence of the general fact. His public cares were unremitted even after he had begun to ſuffer moſt ſeverely under the ſymptoms which attended a gradual decline. He viewed with philoſophic ſerenity his approaching end, and continued to exerciſe with his accuſtomed regularity the functions of royalty, till within two days of his death. He remained in the full poſſeſſion of thoſe uncommon powers of underſtanding, by which he was diſtinguiſhed, till the 15th of Auguſt, and reſigned his breath Auguſt 17, 1786, in the ſeventy-fifth year of his age, and the forty-ſeventh of his reign.

Frederic had unqueſtionably a claim to be ranked among thoſe princes who are called *Great:* as a general, though liable to error, yet his enterprize and comprehenſion, the accuracy with which he directed complicated plans, his foreſight in providing for all wants and exigencies, the boldneſs of his deſigns, and the vigour of his execution, have rarely been ſurpaſſed ſince the time of Cæſar. That he was laviſh in the lives of his ſoldiers, has been imputed to a defect rather of feeling than of judgment. He conſidered them as the inſtruments put into his hands for the purpoſe of playing a great game, and he made it finally a winning one. His political talents were conſiderable, and adapted to the rank he held in the world as an abſolute monarch. In perſon he was ſomewhat below the middle ſtature, but his limbs were well formed, and he poſſeſſed a healthful and vigorous conſtitution. His intellectual powers were great, and his acquirements in literature were very reſpectable. He had much general knowledge of the ſciences, and was converſant with the beſt French writers on polite literature: but his ſkill in the ancient authors was derived through the medium of French tranſlations; his character and conduct varied very much with the ſituations which he was called to fill; his predominant paſſion was the love of glory, and he was ambitious to unite in his own perſon the reputation of a great king, a wiſe legiſlator, an illuſtrious hero, an accompliſhed general, a fine poet, and an enlightened philoſopher. His judgment was naturally ſolid, but in ſome degree perverted by his early prejudices in favour of the French ſchool, and this will eaſily account for his diſbelief of revealed religion; his notions with reſpect to natural religion ſeem to have fluctuated; but his morals were uniformly guided by no other rule than his pleaſure, and what

he

he believed to be his intereſt. He was capable of ſevere and very cruel actions, and hence he was characterized by Voltaire, once his friend and idol, from a marble table that ſtood by him, as *hard* and *poliſhed*. (See VOLTAIRE.) The love of juſtice and the principles of humanity took their turns in his mind, and examples are recorded of his clemency and placability; theſe are, however, but few in compariſon of the cruelties which the inhabitants of Saxony, of Poland, and other conquered places can teſtify againſt the Great Frederic, to ſay nothing in this place of enormities practiſed on individuals. (See TRENCK, *Baron*.) As an author, beſides the works already referred to, he publiſhed "Military Inſtructions," and other pieces on miſcellaneous topics, compoſing four volumes octavo under the general title of "Œuvres Primitives." After his death appeared his poſthumous works in 15 vols. of which the principal are "The Hiſtory of his own Time:" "The Hiſtory of the ſeven years' War:" and "Memoirs from the peace of Hubertſburg to the partition of Poland in 1775." To theſe we have had occaſion to refer, but the reader is particularly directed for an able account of this great man and illuſtrious monarch, to Dr. Towers's "Mem. of Frederick king of Pruſſia."

FREDERICA, in *Geography*, a port town of America, in the ſtate of Georgia and county of Glyan, pleaſantly ſituated in St. Simon's iſland, on an eminence upon a branch of Alatamaka river, which forms a bay before the town, and affords a ſafe and commodious harbour for veſſels of the largeſt burden, which may lie along the wharf. It was ſettled by ſome Scots highlanders about the year 1735, who accepted an eſtabliſhment both here and at Darien to defend the colony, if needful, againſt the neighbouring Spaniards. N. lat. 31° 15'. W. long. 80°.

FREDERICIA, a ſtrong ſea-port town of Denmark, in North Jutland, and dioceſe of Ripen; ſituated on the Little Belt, with a cuſtom houſe, where all veſſels pay toll. The circumference is extenſive, but not filled with houſes or people. It was founded in 1651 by Frederic III.; and in 1682 Chriſtian V., in order to increaſe the number of its inhabitants, granted a charter, which rendered it an aſylum for all bankrupts, both natives and foreigners, and allowed the Calviniſts, Papiſts, and Jews, free exerciſe of their religion. Fredericia has ſeveral commercial privileges, but as it wants a good harbour, they are incapable of much improvement. It has two Lutheran churches, a Calviniſt church, a Popiſh church, a ſynagogue, a grammar ſchool, and good arſenal. A quantity of tobacco is planted both within and without the walls. N. lat. 55° 35'. E. long. 9° 44'.

FREDERICK, a county of Maryland, in America, bounded N. by Pennſylvania, W. and N.W. by Waſhington, E. by Baltimore, and S.W. by Potowmack river. On the Monocacy river and its branches are about 37 griſt mills, a furnace, iron forge, and a glaſs manufactory, called the "Ætna glaſs works," which are in a thriving ſtate. This county is more than 30 miles each way reckoning from the extreme parts, and is divided into 12 towns and villages. The Cotoctiny mountain extends from the Potowmack in a N. direction through this county into Pennſylvania, between the ſouth mountain and Monocacy creek; the eaſtern parts are generally level. It contains 30,791 inhabitants, including 3641 ſlaves. The lands of this county are generally rich, producing wheat, rye, barley, corn, hemp and flax. Mines of copper have been diſcovered. It comprehends about 537,600 acres. Its chief town is called Frederick town.—Alſo, a county of Virginia, bounded north by Berkeley, S. by Shanandoah, W. by Hampſhire, and E. by Shanandoah river, which ſeparates it from London county. It is 30 miles in length, and 20 in breadth, and contains 16,257 white inhabitants, and 5118 ſlaves. It abounds with iron ore, and works have been erected which produce 160 tons of bar iron, and 650 tons of pig, annually. Both this and Berkeley county have a good ſoil. Between the waters of Opeckan creek and the Shanandoah is the richeſt lime ſtone land in the eaſtern parts of the ſtate. Near the north mountain in this county is a curious cave, by ſome called "Zancy's cave." After entering this cave a few feet, the mercury, which, in the open air, was at 50, roſe to 57 of Fahrenheit's thermometer. Beſides this, there is a natural well of unknown depth. The chief town of the county is Wincheſter.

FREDERICK *Henry's Bay*, a bay on the coaſt of New Holland, diſcovered by Taſman in 1642. S. lat. 43° 10'.

FREDERICK-*Henry Cape*, the north point of Adventure bay, in New Holland. S. lat. 42° 42'. E. long. 147° 37'.

FREDERICK *Houſe*, a trading ſtation in Upper Canada, on the head water of Abbitibbe river. N. lat. 48° 35'. W. long. 82° 6'.

FREDERICK, a fort in Waſhington county, Maryland, ſituated on the N.E. bank of Potowmack river, near the S. line of Pennſylvania.—Alſo, a townſhip in Montgomery county, Pennſylvania, containing 697 inhabitants.—Alſo, a town on the N. ſide of Saſſafras river in Cecil county, Maryland, and ſeparated by that river from George town, in Kent county. It lies ſix miles S.W. of Warwick. N. lat. 39° 22' 30".

FREDERICK *Point*, in Upper Canada, lies on the W. ſide of Kingſton harbour, and on the weſt ſide of Haldamand Cove, which is made by this point, and point Henry.

FREDERICKENBURG, a town of Germany, in the principality of Anhalt Zerbſt; one mile S.W. of Zerbſt.

FREDERICKRODE, a town of Saxony, in the principality of Gotha; ſix miles S. of Gotha.

FREDERICKSBORG, a town of Denmark, in the iſland of Zealand; 18 miles N.N.W. of Copenhagen. N. lat. 55° 56'. E. long. 12° 20'.

FREDERICKSBURG, a town of Germany, in the duchy of Pomerania; 25 miles N.N.E. of Stargard.

FREDERICKSBURG, a poſt town of America, in Spotſylvania county, Virginia, on the S.W. bank of Rappahannock river, 110 miles from its mouth in Cheſapeak bay. It is an incorporated town, and laid out into ſeveral ſtreets, of which the principal runs parallel with the river, and contains about 300 houſes, two tobacco warehouſes, and ſeveral ſtores of well aſſorted goods. Its public buildings are, an epiſcopal church, an academy, court houſe and gaol. It is a place of conſiderable trade, and contains about 2000 inhabitants. It has a forge in its vicinity; which works about 300 tons of bar iron in a year, from pigs imported from Maryland. It is 50 miles S.W. of Alexandria, 102 S.W. of Baltimore, and 205 S.W. of Philadelphia. N. lat. 38° 22'. W. long. 77° 36'.

FREDERICKSBURG, a townſhip in the county of Lenox, Upper Canada, which lies to the weſt of Erneſt town, in the bay of Quinté.—Alſo, a townſhip of Dutcheſs county, in New York, ſituated between Franklin and Phillipstown, and containing 1661 inhabitants. N. lat. 41° 31'. W. long. 73° 38'.—Alſo, a town of Africa, on the Gold coaſt. N. lat. 6° 40'.

FREDERICKSHALL, a ſea-port town of Norway, on the frontiers of Sweden, at the mouth of the river Tiſſe, in a bay called the Swineſund; the harbour would be ſafe and commodious, if it were not for the quantity of ſaw-duſt brought down the river from the ſaw-mills up the coun-

country, which it is neceſſary to remove yearly. The town contains about 3000 inhabitants. The ſtreets are airy; and the houſes are built of wood painted red, and a few white. The principal commerce of the town conſiſts in the exportation of planks to England. The wood is floated down the Tiſte ſometimes above 100 Engliſh miles from the interior parts of the country, and ſawed here; for which purpoſe 36 ſaw-mills are erected on the banks of the river, which forms a ſeries of cataracts. The port poſſeſſes a few immunities; goods landed for exportation pay no duty, unleſs opened for home conſumption; and then they are charged with the uſual impoſts. On the ſummit of an almoſt perpendicular rock, which overhangs the town, ſtands the ſtrong and hitherto impregnable fortreſs of Frederickſtein, rendered memorable by the death of the northern lion, as Charles XII. is ſometimes emphatically ſtyled; 52 miles S. of Chriſtiania.

FREDERICKSHAM, a town and fortreſs of Ruſſia, in the government of Wiburgh or Viborg, formerly belonging to Sweden when it was only a ſmall village, in the province of Finland, but ceded to the Ruſſians by the peace of Abo. The town is ſmall and regular; in the centre is a ſquare, from which the ſtreets extend at right angles. The houſes, excepting one of brick, are all built of wood in the neateſt manner. The fortifications are ſtrong; and the garriſon and ſeveral companies of ſoldiers, quartered in the neighbouring villages, amount to 6000 troops. The inhabitants carry on a ſmall commerce with England and Holland, exporting planks and tallow, and importing ſalt and tobacco. In 1783, Frederickſham was the ſcene of an interview between Catharine empreſs of Ruſſia and Guſtavus king of Sweden, which continued three days. The empreſs, with a magnificence, before unknown to theſe northern regions, erected a wooden palace, which contained a grand ſuite of apartments, and a theatre, in which French plays were acted. This town is diſtant 50 miles W. from Viborg or Wiburgh. N. lat. 60° 36'. E. long. 28° 18'.

FREDERICKSHOLM, a fortreſs of Norway; three miles S. of Chriſtianſand.

FREDERICKSTADT, a fortreſs and ſea-port town of Norway, ſituated on the river Glomme, nearly 26 Engliſh miles from Frederickſhall. This is the moſt regular fortreſs in this part of Norway, and contains an arſenal amply ſupplied with arms for the militia, in caſe of a rupture with Sweden. It was built in 1567 by Frederic II., ſtrengthened by Frederic III., and ſince gradually enlarged and fortified, according to the modern ſyſtem. The ramparts incloſe a circumference of $\frac{3}{4}$ of a mile, and the population of the town, including the two ſuburbs, amounts to no more than 800 perſons. The inhabitants export planks, and a few ſmall maſts. Cloſe to Frederickſtadt is the new fortreſs of Kongſteen, on a rocky eminence, capable of containing a garriſon of 300 men; ſeveral convicts are here condemned to hard labour. The greateſt offenders have an iron cap, chains round their arms, legs, and bodies; the chains round their arms are rivetted to a wheel-barrow, which is never looſened. Frederickſtadt is 43 miles S. of Chriſtiania. N. lat. 59° 2'. E. long. 11° 1'.

FREDERICKSTADT, a town of Denmark, in the duchy of Sleſwick, ſituated on the north coaſt of the Eider; founded by ſome Dutch Arminian emigrants immediately after the ſynod of Dort. The inhabitants conſiſt of Arminians, Lutherans, Calviniſts, Anabaptiſts, Quakers, and Jews. They are chiefly employed in ſilk or woollen manufactures navigation, and commerce; 18 miles W.S.W. of Sleſwick. N. lat. 54° 28'. E. long. 9° 11'.

FREDERICKSTADT. See BERLIN.

FREDERICKSTHAL, a town of Saxony, in the margraviate of Meiſſen; ſix miles W. of Senftenberg.

FREDERICKSUND, a ſea-port town of Denmark, in the iſland of Zealand, ſituated in the gulf of Roſchild. Its chief trade is in corn; 19 miles N.W. of Copenhagen. N. lat. 55° 50'. E. long. 12° 5'.

FREDERICKSVORN, a town of Norway, in the province of Aggerhuus; 3 miles S. of Laurvig.

FREDERICKSWALDE, a town of Germany, in the duchy of Pomerania, on the Ihna; five miles N.W. of Stargard.

FREDERICKSWERK, a ſea-port town of Denmark, ſituated near the Iſe-fiord, a bay of the ſame ſea on the northern ſhore of Zealand, where general Clauſſen, in the year 1756, eſtabliſhed various manufactories, a foundery for cannon, and other works for ſupplying the Daniſh army and navy with ſtores. He alſo new-formed the canal, connecting a ſmall lake with the Iſe-fiord, which had been begun in 1717 by order of Frederic IV., in order to prevent the inundation of the lakes from overflowing the royal eſtates; and hence the place was called Frederickſwerk. The general alſo planted the adjacent country, for the ſpace of ſeveral miles, which was either a moraſs, or covered with drifted ſand; and thus he has ſucceeded in performing a work which Frederic IV. had attempted in vain, *viz.* that of fertilizing this waſte. By theſe means a tract of country which before only fed thirty-two cows, now yields, beſides a large quantity of fire-wood, in a favourable ſeaſon, above 500 loads of hay.

FREDERICKSWERTH, a town of Germany, in the principality of Gotha; 5 miles N.W. of Gotha.

FREDERICKTON, a conſiderable townſhip of America, in the province of New Brunſwick; 90 miles up St. John's river, which is ſo far navigable for ſloops.

FREDERICKTOWN, a poſt-town of Maryland, and capital of Frederick county, ſituated on both ſides of Carrol's creek, a ſmall ſtream that diſcharges itſelf into Monocacy river, over which are two bridges. The ſtreets are regularly laid out, interſecting each other at right angles. The dwelling houſes are about 200 in number, of which ſeveral are commodious and handſome. The public edifices are one church for Preſbyterians, two churches for German Lutherans and Calviniſts, and one for Baptiſts, an elegant court-houſe and gaol, and convenient market-houſe. Its trade is conſiderable with the back country. The Ætna glaſs works are ſituated four miles above the town, in Tuſkarora creek. It is 47 miles W. by N. from Baltimore, and 148 S.W. by W. from Philadelphia. N. lat. 39° 24'.

FREDOLFO, a torrent of Switzerland, in the county of Bormio, which, paſſing by the town of Bormio, falls at a ſmall diſtance into the Adda.

FREDON, Fr. in *Muſic*, an old word for a rapid paſſage or diviſion. *Roulade* is at preſent uſed for the ſame purpoſe, with this difference, that the *roulade* is of longer duration, and is written, whereas the *fredon* was an extemporaneous flouriſh at a pauſe, *ad libitum*.

FREDONIA, in *Geography*, a generic name which is ſuggeſted in Dr. Morſe's Gazetteer as proper for comprehending the whole territory now under the government of the United States; bounded N. by Upper and Lower Canada, E. by New Brunſwick and the Atlantic ocean, S. by Florida and the gulf of Mexico, W. by New Mexico and the Shining mountains, which divide the weſtern waters of the Miſſiſippi from thoſe which fall into the Pacific ocean. This territory lies between 28° and 50° N. lat. and 66° and 116° W. long.

long. from Greenwich. Its extreme length from E. to W. is upwards of 2000 miles, and its extreme breadth about 1500. It is eſtimated to contain nearly 2,000,000 ſquare miles, or about four-fifths as many as are contained in all Europe. It is about twice the ſize of the Chineſe empire, and if we except Ruſſia, it is by far the largeſt territory on earth, whoſe inhabitants live under the ſame general government. The Miſſiſippi river divides Fredonia nearly in its centre, leaving 1,000,000 ſquare miles E. of it, in the preſent United States, and nearly the ſame number of ſquare miles W. of it. The vale, if it may be ſo called, between the Alleghany and Shining mountains, which is interſected by the Miſſiſippi, and watered by its numerous and large eaſtern and weſtern branches, contains nearly a million and a half ſquare miles, and may be reckoned among the fineſt portions of the globe. Fredonia has a ſea-coaſt of many thouſand miles in extent, along which are but few iſlands of much importance, but full of harbours, many of them equal to any in the world. Its mountains, lakes, and rivers, are all upon a large ſcale. Its climate and ſoil are adapted to almoſt all the variety of productions which the earth affords. Over the vaſt ſurface of Fredonia are ſcattered, in ſome parts (particularly New England) thickly, but generally very ſparingly, about five millions and a half of inhabitants, excluſively of Indians, a ſeventh part of whom is in ſlavery. The Fredonians, except the aboriginal inhabitants, and the negroes imported from Africa, and their deſcendants of every ſhade, are a people collected from almoſt every nation in Europe, and their poſterity. For a deſcription of *Louiſiana*, ſee that article. The great difference in climate, in the modes of obtaining ſubſiſtence, in language, religion, and political opinions, and conſequently in the feelings and intereſts of the inhabitants throughout this vaſt territory, may for ever prevent any great ſimilarity of character. The unavoidable induſtry and hardihood of the north will always form a harſh contraſt to the eaſe and indulgence of the ſouth. What effect, however, ſays Dr. Morſe, a generic name would have in forming an uniform national character, in defiance of all theſe obſtacles, remains to be tried. Such a name has long been a deſideratum. The author has formed an article Fredonia as a ſpecimen of the advantage and convenience of ſuch a name.

FREDONNER, Fr. in *Muſic*, this word is only uſed in deriſion, as we ſay *quavering*.

FREDOREA, in *Geography*, a ſmall iſland on the eaſt ſide of the gulf of Bothnia. N. lat. 63° 1′. E. long. 20° 59′.

FREDUM, in *Antiquity*, a compoſition made by a criminal to be freed from proſecution, a third part of which was paid into the fiſcus or exchequer; or it was the price paid to the magiſtrate for protection againſt the violences of reſentment. In ſome extraordinary caſes, where it was more difficult to protect the perſon who had committed violence, the fredum was augmented. Monteſq. de l'Eſprit des Loix, lib. xxx. cap. 20. and Robertſon's Hiſt. vol. i. chap. v. p. 361.

FREE, a term variouſly uſed; but generally in oppoſition to conſtrained, confined, or neceſſitated. (See FRANK.) Thus, a man is ſaid to be free, who is out of priſon; and a bird is free when let out of the cage: free from pain, *i. e.* void of pain; we ſay, a free air, a free paſſage, &c.

FREE, in ſpeaking of things endowed with underſtanding, has a more peculiar relation to the will, and implies its being at full liberty.

The Stoics maintain that their ſage or wiſe men alone are free. See LIBERTY.

FREE is alſo uſed in oppoſition to ſlave.

The moment a ſlave ſets foot on Engliſh ground, he becomes to ſome purpoſes free. The fineſt legacy the ancient Romans could leave their ſlaves, was their freedom. See LIBERTY.

FREE, *aboard a Ship*. The ſeamen ſay the pump frees the ſhip, when it throws out more water than leaks into her; but, on the contrary, when it cannot throw out the water as faſt as it leaks in, they ſay the pump cannot free her: alſo bailing or lading out water out of a boat is called freeing the boat.

FREE *Agent*. See AGENT.

FREE *Bench*, or *Franc Banc*, ſignifies that eſtate in copyhold lands, which the wife hath after the deceaſe of her huſband, for her dower, according to the cuſtom of the manor.

Fitzherbert calls free banc a cuſtom, whereby, in certain cities, the wife ſhall have her huſband's whole lands, &c. for her dower.

Thus, at Orleton, in the county of Hereford, the relict of a copyhold tenant is admitted to her free bench, *i. e.* to all her huſband's copyhold land, during her life, at the next court after her huſband's death.

In the manors of Eaſt and Weſt Enbourne, in Berks, if a cuſtomary tenant die, the widow ſhall have a free bench in all his copyhold lands, only *dum ſola & caſta fuerit*: if ſhe commits incontinency, ſhe forfeits her eſtate; but if ſhe will come into court, riding backwards on a black ram, with his tail in her hand, rehearſing a certain form of words, in the nature of a confeſſion and petition, the ſteward is bound by the cuſtom to reſtore to her her free bench. The words are theſe:

> "Here I am
> Riding upon a black ram,
> Like a whore as I am:
> And for my crincum crancum
> I have loſt my bincum bancum.
> And for my tail's game
> Have done this worldly ſhame.

Therefore, pray, Mr. Steward, let me have my land again."

The like cuſtoms hold alſo in the manor of Chadleworth, in Berks; that of Tor, in Devonſhire; and in ſome other parts of the weſt.

FREE-*booter*, or *Flibuſter*, a name given to the pirates who ſcour the American ſeas; particularly ſuch as make war againſt the Spaniards.

The French call them *flybuſters*, deducing the word from the Engliſh *flibote*, or *flybote*; becauſe the firſt adventurers of this kind were the people of St. Domingo, who made their excurſions with flybotes, which they had taken from the Engliſh. See BUCCANEER.

Free-booter is a perſon who, without regard to any laws, poſſeſſes himſelf of whatever property chance may throw in his way, and for the aquiring of which he joins with others of a ſimilar deſcription, in order that they may be capable of undertaking various enterpriſes, and to make more certain of ſucceſs. The free-booter is the ſame on ſhore that the pirate is on the ſeas; though inſtances may be adduced in which the latter not only made prize of whatever fell in their way while cruiſing on the ocean, but held authority over territorial poſſeſſions, and thus by carrying on their depredations in both ſituations, become free-booters; of this claſs were the buccaneers, ſo long celebrated for their daring exploits.

Some nations are nothing better than free-booters: thus

we ſee that the Arab hordes which frequent the deſerts make no diſtinction whatever in regard to the difference of nations. Theſe people, while in one quarter they profeſs to be at peace with all the world, in other ſituations deem all to be enemies who poſſeſs property to ſuch amount as may be worth contending for.

Unfortunately, we have of late years ſeen, that the rulers of great and populous kingdoms could ſo far diſregard every principle of juſtice, and ſo abuſe that confidence which had placed them on the throne, as to become free-booters in the moſt literal ſenſe of the deſignation. With ſuch, no tie, no claim could induce to forbearance where there ſeemed an opening for the plundering of contiguous, or even remote nations, notwithſtanding they might, by their generoſity, or by their forbearance, have eſtabliſhed a claim, not only to exemption from rapine, but to the moſt grateful acknowledgments.

The free-booter, like the pirate, is an outlaw among all the civilized nations of the world, and when in the power of any, ought, on no conſideration, to experience the ſmalleſt portion of lenity. Men inured, as they conſtantly are, to the perpetration of the moſt barbarous deeds, and who conſider the univerſe to be their property, can never be reclaimed: conſequently humanity, as well as policy, dictates, that a war of extermination ſhould be carried on againſt them. We ſpeak of this as alluding to profeſſed banditti, obſerving that in the boſom of every nation with which we are acquainted a gang of free-booters will be found, whether under the deſignation of gypſies, or under the more common title of paupers, to infeſt various parts, where, owing to local circumſtances, they are too often more than tolerated. The perſon who may propoſe an efficient remedy for this evil will richly deſerve the thanks of his country.

FREE *Bord, franc bord.* In ſome places three feet, in others more, and in others leſs, is claimed by way of free bord, beyond or without the fence.

"Et totum boſcum, quod vocatur brendewode, cum franc bordo duorum pedum & dimid. per circuitum illius boſci." Mon. Ang. 2d part, fol. 241.

FREE *Chapel*, is a chapel founded by the king, and by him exempted from the juriſdiction of the ordinary. See CHAPEL.

A ſubject may alſo be licenſed by the king to build ſuch a chapel, and by his charter may exempt it from the viſitation of the biſhop, &c.

FREE *Coals*, are ſuch as do not crozle or cement together in the burning, but remain in ſeparate lumps.

FREE or *Imperial Cities*, in Germany, are thoſe not ſubject to any particular prince; but governed, like republics, by their own magiſtrates.

There were free cities, *liberæ civitates*, even under the ancient Roman empire: ſuch were thoſe to which the emperor, by the advice or conſent of the ſenate, gave the privilege of appointing their own magiſtrates, and governing themſelves by their own laws. See CITY.

FREE *Fair*. See FAIR.

FREE *Fee*. See FEE and FRANK.

FREE *Fiſhery*. See FISHERY.

FREE *Martin*, in *Rural Economy*, a term ſignifying a barren heifer that has been a twin with a bull-calf.

FREE-*maſon*. See MASON.

FREE *Port*. See PORT.

FREE *Service*. See SERVICE.

FREE *Socage*. See SOCAGE.

FREE *State*, is a republic governed by magiſtrates elected by the free ſuffrages of the inhabitants.

FREE-*ſtone*, a whitiſh ſtone, dug up in many parts of England, that works like alabaſter; but is more hard and durable, being of excellent uſe in building, &c.

It is a kind of the gritt ſtone, but finer ſanded, and a ſmoother ſtone; and is called free-ſtone, from its being of ſuch a conſtitution as to be cut freely in any direction. This is a ſpecies of the pſaduria of Hill.

The qualities of the ſeveral kinds of free-ſtone, in common uſe in the ſeveral parts of Europe, are very different. They all agree in this general property indeed, that they are ſofter while in the quarry than when they have been ſome time expoſed to the air: but even this general property differs greatly in degree. They have a ſort of grey free-ſtone in uſe at Paris, of which we do not ſeem yet to have met with any quarries in England, though probably enough there are ſuch, which has this property in ſo eminent a degree, that the expence of working it is in a great meaſure ſaved.

This ſtone lies every where on the ſouth ſide of the river Seine, and is of a coarſe and large gritt. It is ſo ſoft when newly taken out of the ſtrata, that they cut it very conveniently with a ſort of broad axe, and faſhion as many ſtones for building in this manner in an hour, as an equal number of our people do in a day or two. Though this ſtone is as ſoft as dry clay when firſt taken up, it is found to harden ſo conſiderably in the air, that it becomes more than equal to our ordinary free-ſtone.

Our Portland ſtone, of the fineſt kind, which is white, and of a cloſe gritt, is very fit for hewing or carving, but it will neither reſiſt water nor fire, which is a very ſingular circumſtance in ſo denſe a ſtone; while the free-ſtone of Kent, which is leſs beautiful to the eye, and is of a greyiſh colour, and conſiderably cloſe, though of a larger grain, reſiſts the air and water very well.

The free-ſtone of Derbyſhire, on the other hand, is ſo brittle as to be unfit for any fine working, and ſo coarſe and open in its texture that it lets water through; yet it bears the fire extremely well, and is fit for ovens, hearths, &c. Phil. Tranſ. N 93.

FREE *Stool*. See FRIDSTOLL.

FREE-*thinker*. See DEIST.

FREE-*warren*. See WARREN.

FREE-*will*. See WILL.

FREE-BOOTER's POINT, in *Geography*, a cape at the weſtern extremity of the iſland of Anagada in the Weſt Indies.

FREEDOM, the quality or ſtate of being free. See FREE.

FREEDOM *of a City, Town*, &c. denotes a right or capacity of exerciſing a certain trade or employment in that city or town corporate, and of being elected to the dignities and offices thereof. It is procured regularly, by ſerving an apprenticeſhip; but ſometimes purchaſed with money, and ſometimes conferred as a favour or compliment.

FREEDOM *of the Will*, a ſtate or faculty of the mind, wherein all the motions of our will are in our power, and we are enabled to determine on this or that; to do good or evil, without any force or conſtraint from any external cauſe whatever. See LIBERTY, and NECESSITY.

FREEDOM *of Conſcience*. See LIBERTY, and TOLERATION.

The ſchoolmen diſtinguiſh two kinds of this freedom, *viz.*

FREEDOM *of Contradiction*, whereby we are at our choice to will, or nill; to love, or not to love, &c.

Thus, if I give my friend a power to take my horſe, that friend has freedom of contradiction with reſpect to the horſe; ſince it is in his own power either to uſe him, or let him alone.

FREEDOM *of Contrariety*, or of *Contraries*, is that whereby

we are at our choice to do good or evil, to be virtuous or vicious.

Thus, if I offer my friend a horſe, or a lion, and give him his option of the two, he is ſaid to have a liberty of contrariety over the horſe and lion.

But the logicians charge this as a faulty or unartful diviſion, becauſe one member of the diviſion is contained in the other, as a ſpecies in the genus; for whatever is free, in reſpect of contradiction, is alſo free in reſpect of contrariety, though not *vice verſâ*: for if it be free for my friend to take the horſe, or the lion, it is alſo free for him to let them both alone; but he may be free to take one of them, without a freedom of chuſing which to take.

Yet the diſtinction is of ſome uſe; as it intimates, that the will is not always poſſeſſed of both kinds of freedom, and that the matter or ſubject of the two is different.

The will, though it ſhould be allowed to be free, has not a liberty of contrariety: thus, any evident truth being propoſed to the mind, *e. gr.* that the whole is greater than a part, though we may have a power of not aſſenting thereto, by diverting our attention to ſomething elſe, yet we have not a power of diſſenting from that propoſition, and judging that the whole is not greater than the part.

Hence moraliſts commonly hold, that with reſpect to the ſupreme good, man has a liberty of contradiction, inaſmuch as he may abſtain from the love or purſuit thereof; but he has not a liberty of contrariety, whereby to hate goodneſs.

Add, that though the human mind may have a freedom of contradiction with reſpect to all objects, even the ſupreme good itſelf; yet the freedom of contrariety is reſtrained to certain particulars, which either are, or appear to be good; the will having ſuch a natural propenſity to be good, that it cannot deſire evil, but under the notion and appearance of good.

FREEDOM *of Thinking*. See DEISM.

FREEHOLD, in *Geography*, a poſt town of America, in Monmouth county, New Jerſey; 15 miles W. of Shrewſbury, and 20 S. E. by S. of New Brunſwick. Freehold has an academy, and, in 1790, contained 3785 inhabitants.

FREEHOLD, *Upper*, a townſhip of New Jerſey, in Monmouth county, W. of Freehold. In 1790, it contained 3442 inhabitants.

FREEHOLD, a poſt town in Green county, New York, containing 3812 inhabitants.

FREEHOLD, *Frank Tenement, liberum tenementum*, in *Law*, is land, or tenement, which a man holds in fee-ſimple, fee-tail, or for term of life. (Bract. l. ii. c. 9.) An eſtate of freehold is defined by Britton (c. 32.) to be "the poſſeſſion of the ſoil by a freeman." And St. Germyn (Dr. and Stud. b. 2. d. 22.) tells us, that "the poſſeſſion of the land is called in the law of England the frank tenement or freehold." Such eſtate, therefore, and no other, as requires actual poſſeſſion of the land is, legally ſpeaking, *freehold*; which actual poſſeſſion can by the courſe of the common law be only given by the ceremony called "livery of ſeiſin," which is the ſame as the feodal inveſtiture. From theſe principles, ſays judge Blackſtone, we may extract this deſcription of a freehold: that it is ſuch an eſtate in lands as is conveyed by livery of ſeiſin, or, in tenements of an incorporeal nature, by what is equivalent thereto. Accordingly it is laid down by Littleton (ſ. 59.) that where a freehold ſhall paſs, it behoveth to have livery of ſeiſin. As therefore eſtates of inheritance, and eſtates for life, could not, by common law, be conveyed without livery of ſeiſin, theſe are properly eſtates of freehold; and as no other eſtates were conveyed with the ſame ſolemnity, therefore no others are properly freehold eſtates. See ESTATE.

Freehold is of two kinds, in *deed*, and in *law*. The firſt is the real poſſeſſion of land or tenement in fee, fee-tail, or for life: the other is the right a man has to ſuch land or tenement before his entry or ſeizure.

A freehold, by the common law, cannot commence *in futuro*, but it muſt take effect preſently, either in poſſeſſion, reverſion, or remainder. (5 Rep. 94.) Whatever is part of the freehold goes to the heir; and things fixed thereto, as glaſs windows, wainſcot, &c. cannot be removed by tenants, nor taken in diſtreſs for rent, or in execution, &c. No man ſhall be diſſeiſed of his freehold by ſtat. Magna Charta, cap. 29. but by judgment of his peers, or according to the laws of the land: nor ſhall any diſtrain freeholders to anſwer for their freehold, in any thing concerning the ſame, without the king's writ. (Stat. 52 Hen. III. c. 22.) Freehold eſtates of certain value are required by ſtatutes to qualify jurors, electors of the knights of the ſhire in parliament, &c.

For the method of finding the value of freehold eſtates, ſee ANNUITIES and LIFE-ANNUITIES.

FREEHOLD is likewiſe extended to ſuch offices as a man holds in fee, or for life.

FREEHOLD is alſo ſometimes taken in oppoſition to villenage.

Lambard obſerves, that land, in the Saxons' time, was diſtinguiſhed into bockland, *i. e.* holden by book, or writing; and folkland, held without writing.

The former, he ſays, was held on far better condition, and by the better ſort of tenants, as noblemen and gentlemen; and being ſuch as we now call freehold; the latter was moſtly in poſſeſſion of peaſants; being the ſame with what we now call "at the will of the lord."

In the ancient laws of Scotland, freeholders are called *milites*, knights. In Reg. Judicial, it is expreſſed, that he who holds land upon an execution of a ſtatute-merchant, until he hath ſatisfied the debt, "tenet ut liberum tenementum ſibi et aſſignatis ſuis;" and the ſame of a tenant per elegit; the meaning of which ſeems to be, not that ſuch tenants are freeholders, but as freeholders for the time, till they have received profits to the value of their debt.

FREEING *a* MINE, is paying the firſt diſh of ore obtained therefrom to the farmer of the king's dues in the king's field.

FREELS, CAPE, in *Geography*, a cape on the eaſt coaſt of Newfoundland. N. lat. 49° 35'. W. long. 53° 10'.

FREEMONT, a cape on the north coaſt of the iſland of Jerſey; 5 miles N. of St. Helier.

FREEPORT, a poſt-town of America, in Cumberland county, Maine, at the head of Caſco bay; adjoining to Durham on the N.E. and to North Yarmouth on the S.W.; 10 miles N.E. of Portland, and 140 N. by E. of Boſton: it was incorporated in 1789, and contains 1330 inhabitants. A mine of ſilver and lead, it is ſaid, has been diſcovered in this town.

FREETOWN, a thriving townſhip in Briſtol county, Maſſachuſets, incorporated in 1683, containing 2535 inhabitants, and lying 45 miles ſoutherly of Boſton. The ſouthern part of this town has been lately incorporated into a new town, by the name of Fall River.

FREEWILL's ISLANDS, three ſmall iſlands in the Eaſt Indian ſea, diſcovered by Capt. Carteret in the year 1767: called

called reſpectively, Pegan, Onata, and Onella. They are wholly ſurrounded by a reef of rocks, except towards the eaſt, where is a paſſage for a canoe. Pegan is ſituated about two miles north from the other two, which lie near each other in an eaſt and weſt direction. The inhabitants were friendly, and ready to exchange their cocoa nuts for ſmall pieces of iron, which they valued highly. They are of the Indian copper colour, with fine long black hair, and ſmall beards, which they were continually plucking by the roots from their chin and upper lip. Their features are pleaſing, and their teeth remarkably white and even; they are of the common ſtature, but ſingularly nimble, active, and vigorous. Their diſpoſition is free and open, and they aſſociated with the crew as familiarly as if they had been long acquainted. On their waiſt they had a ſlight covering, which conſiſted of fine matting. Their canoes are well conſtructed, having a hollow tree for the bottom, and planks for the ſides, with a ſail of fine matting, and an outrigger, and good ropes and netting. One of the inhabitants inſiſted on remaining with the ſhip's crew, who was named Joſeph Freewill, and from whom they learned that there were other iſlands towards the north, whoſe inhabitants had iron, and who always killed his countrymen when they met at ſea. The iſlands were ſmall and low, the larger not being more than five miles in compaſs, to which the captain gave the name of Freewill iſland. S. lat. 0° 50'. E. long. 137° 51'.

FREEZE, in *Architecture*, the middle ſubdiviſion of the entablature, ſeparating the cornice from the architrave.

The ancients called it *zoophorus*, ζωυφορος, becauſe it was uſually enriched with figures of animals; and our denomination freeze has a like origin, being formed of the Latin *phrygio*, an embroiderer, becauſe it is commonly adorned with ſculptures in baſſo relievo, imitating embroidery.

The freeze is ſuppoſed to be intended to repreſent the heads of the tranſverſe beams that ſuſtain the roof or covering.

In the Tuſcan order, the freeze is a plain flat member; in the Doric it is ornamented with tablets, which are cut into vertical, triangular grooves called triglyphs; and in the Ionic and Corinthian it is a plane ſurface; that of thoſe in the latter order is ſometimes enriched. The peculiarities reſpecting the freeze will be ſeen under the head of each individual order. See alſo COLUMN.

From the variety of enrichments practiſed on the freezes, they become variouſly denominated: as,

FREEZES, *Convex*, or *Pulvinated*, are thoſe whoſe profile is a curve; the beſt proportion whereof is, when drawn on the baſe of an equilateral triangle.

In ſome, the ſwelling is only at the top, as in a conſole; in others at bottom, as in a baluſter.

FREEZES, *Flouriſhed*, are thoſe enriched with rinds or imaginary foliages, as the Corinthian freeze of the frontiſpiece of Nero; or with natural leaves, either in cluſters or garlands, or continued, as in the Ionic of the gallery of Apollo in the Louvre.

FREEZES, *Hiſtorical*, are thoſe adorned with baſſ-relievos, repreſenting hiſtories, ſacrifices, &c. as that of the arch of Titus at Rome.

FREEZES, *Marine*, are thoſe repreſenting ſea-horſes, tritons, and other attributes of the ſea; or ſhells, baths, grottos, &c.

FREEZES, *Raſtic*, are thoſe whoſe courſes are ruſticated, or imboſſed; as the Tuſcan freeze of Palladio.

FREEZES, *Symbolical*, are thoſe adorned with the attributes of religion; as the Corinthian of the temple behind the Capitol at Rome, whereon are repreſented the inſtruments and apparatus of ſacrifice.

FREEZE *of the Capital*. See HYPOTRACHELION.

FREEZE, in *Commerce*, a kind of cloth or ſtuff. See FRIZE.

FREEZELAND PEAK, in *Geography*, a ſmall iſland in the South Atlantic ocean, near the coaſt of Sandwich land, ſo called from one of Capt. Cook's crew, who diſcovered it in the year 1775. S. lat. 59°. W. long. 27°.

FREEZELAND, *Friezeland*, or *Frizeland horſe*, in *War*, the ſame with *cheval de friſe*.

FREEZING, denotes that operation in nature, by which a liquid, as water, is converted into a ſolid form, as ice. It is effected by the abſtraction of heat from the liquid body, but how this ſhould produce a change in the form or conſtitution of the body, remains ſtill a ſubject for enquiry. It may be imagined that cold is ſomething poſitive, which inſinuates itſelf into the pores of the liquid, and obſtructs the free motion of its particles; but this would require the body to increaſe in weight; or, if we ſuppoſe cold to be void of gravity, ſtill it ſhould tend to increaſe the volume of the liquid; it however generally produces the contrary effect. Some have ſuppoſed that the heat of bodies being diminiſhed, their particles are brought more nearly into contact, and thus the attraction of aggregation or coheſion is increaſed; but in the caſe of water and ice, which is the moſt familiar inſtance we have, the very reverſe takes place; namely, the congealed body, ice, is of leſs denſity than the liquid; and what renders it ſtill more remarkable is, that before the tranſition from liquidity to ſolidity, a gradual expanſion is obſerved in the liquid itſelf during ſome degrees of deſcending temperature. More lately it has been ſuppoſed that a kind of polarity actuates the molecules of liquids, and brings them, in certain caſes, to cohere more forcibly; but this does not account for the phenomena obſerved in regard to change of volume.

Mr. Dalton, in his New Syſtem of Chemical Philoſophy, has given a ſection on the phenomena of the congelation of water, which contains ſome ingenious conjectures on the ſubject. He ſtates the principal facts of congelation as follows: "1ſt. The ſpecific gravity of ice is leſs than that of water, in the ratio of 92 to 100. 2d. When water is expoſed in a large ſuſpended jar to cool in ſtill air of 20° or 30°, it may be cooled 2° or 3° below freezing; but if any tremulous motion takes place, there appear inſtantly a multitude of ſhining hexangular ſpiculæ, floating, and ſlowly aſcending in the water. 3d. It is obſerved, that the ſhoots or ramifications of ice at the commencement, and in the early ſtage of congelation, are always at an angle of 60° or 120°. 4th. Heat is given out during congelation, as much as would raiſe the temperature of water 140° or 150°. The ſame quantity is again taken in when the ice is melted. This quantity may be $\frac{1}{2}$th of the whole heat which water of 32° contains. 5th. Water is denſeſt at 36° of the old ſcale, or 38° of the new: from that point it gradually *expands* by cooling or by heating alike, according to the law ſo often mentioned, that of the ſquare of the temperature. 6th. If water be expoſed to the air and to agitation, it cannot be cooled below 32°; the application of cold freezes a part of the water, and the mixture of ice and water acquires the temperature of 32°. 7th. If the water be kept ſtill, and the cold be not ſevere, it may be cooled in large quantities to 25° or below, without freezing; if the water be confined in the bulb of a thermometer it is very difficult to freeze it by any cold mixture above 15° of the old ſcale (Fahrenheit's); but it is equally difficult to cool the water much below that temperature without its freezing. I have obtained it

as low as 7° or 8°, and gradually heated it again without any part of it being frozen. 8th. In the laſt caſe of what may be called *forced* cooling, the law of expanſion is ſtill obſerved as given above. 9th. When water is cooled to 15° or below in a bulb, it retains the moſt perfect tranſparency; but if it accidentally freeze, the congelation is inſtantaneous, the bulb becoming in a moment opake, and white like ſnow, and the water is projected up the ſtem. 10. When water is cooled below freezing, and congelation ſuddenly takes place, the temperature riſes inſtantly to 32°." He then proceeds as follows: "In order to explain theſe phenomena, let it be conceived that the ultimate or ſmalleſt elements of water are all globular, and exactly of the ſame ſize; let the arrangement of theſe atoms be in ſquares, as exhibited in *Plate* XIV. *Pneumatics, fig.* 4, ſo that each particle touches four others in the ſame horizontal plane. Conceive a ſecond ſtratum of particles placed upon theſe in like order of ſquares, but ſo that each globule falls into the concavity of four others on the firſt ſtratum, and conſequently reſts upon four points, elevated 45° above the centres of the globules. A perpendicular ſection of ſuch globule, reſting upon two diagonal globules of the ſquare, is exhibited in *fig.* 5. Conceive a third ſtratum placed in like manner upon the ſecond, &c. the whole being ſimilar to a ſquare pile of ſhot.—The above conſtitution is conceived to repreſent that of water at the temperature of greateſt denſity.

"To find the number of globules in a cubic veſſel, the ſide of which is given; let n = the number of particles in one line or ſide of the cube, then n is the number in any horizontal ſtratum, and becauſe a line joining the centres of two contiguous particles in different ſtrata makes an angle of 45 with the horizontal plane, the number of ſtrata in the given height will be $n \div$ ſin. of $45° = n \div \frac{1}{2}\sqrt{2}$. Whence the number of particles in the cubic veſſel $= n \div \frac{1}{2}\sqrt{2} = n^3\sqrt{2}$.

"Now let it be ſuppoſed that the ſquare pile is inſtantly drawn into the ſhape of a rhombus, (*fig.* 6.) then each horizontal ſtratum will ſtill conſiſt of the ſame number of particles as before, only in a more condenſed form, each particle being now in contact with ſix others. But to counteract this condenſation, the ſeveral ſucceſſive ſtrata are more elevated than before, ſo that the pile is increaſed in height. A queſtion then ariſes, whether a veſſel of given capacity will hold a greater number of particles in this, or the former diſpoſition? It muſt be obſerved that in the laſt caſe, each particle of a ſuperior ſtratum reſts only on two particles of an inferior one, and is therefore elevated by the ſine of 60°, as repreſented in *fig.* 7. The baſis of the two piles are as $1 : \sqrt{\frac{3}{4}}$, and their heights as $\sqrt{\frac{1}{2}} : \sqrt{\frac{3}{4}}$; but the capacities are as the products of the baſe and height, or as $\sqrt{\frac{1}{2}} : \frac{3}{4}$; that is, as .707 to .750 nearly, or as 94 to 100. Thus it appears that the firſt arrangement contains more particles in a given ſpace than the ſecond, by 6 *per cent.*

"The laſt or rhomboidal arrangement is ſuppoſed to be that which the particles of water aſſume upon congelation. The ſpecific gravities of ice and water ſhould therefore be as 94 to 100. But it ſhould be remembered that water uſually contains 2 *per cent.* in bulk of atmoſpheric air; and that this air is liberated upon congelation, and is commonly entangled among the ice in ſuch ſort as to increaſe its bulk without materially increaſing its weight; this reduces the ſpecific gravity of ice 2 *per cent.*, or makes it .92, which agrees exactly with obſervation. Hence the 1ſt fact is explained.

"The angle of a rhombus is 60°, and its ſupplement 120°; if any particular angles are manifeſted in the act of congelation, therefore, we ought to expect theſe, agreeable to the 2d and 3d phenomena.

"Whenever any remarkable change in the internal conſtitution of any body takes place, whether by the acceſſion and junction of new particles, or by new arrangements of thoſe already exiſting in it, ſome modifications in the atmoſpheres of heat muſt evidently be required; though it may be difficult to eſtimate the quantity, and ſometimes even the kind of change ſo produced, as in the preſent caſe. So far therefore the theory propoſed agrees with the 4th phenomenon.

"In order to explain the other phenomena, it will be requiſite to conſider more particularly the mode by which bodies are expanded by heat. Is the expanſion occaſioned ſimply by the enlargement of the individual atmoſpheres of the component particles? This is the caſe with elaſtic fluids, and perhaps with ſolids, but certainly not with liquids. How is it poſſible that water ſhould be expanded a portion repreſented by 1 upon the addition of a certain quantity of heat at one temperature, and by 340 upon the addition of a like quantity at another temperature, when both temperatures are remote from the abſolute zero, the one perhaps 6000 and the other 6170? The fact cannot be accounted for on any other ſuppoſition than that of a change of arrangement in the component particles; and a *gradual* change from the ſquare to the rhomboidal arrangement, is in all probability effected both by the addition and abſtraction of heat. It is to be ſuppoſed then, that water of the greateſt poſſible denſity has its particles arranged in the ſquare form; but if a given quantity of heat be added to, or taken from it, the particles commence their approach to the rhomboidal form, and conſequently the whole is expanded, and that the ſame, by the ſame change of temperature, whether above or below that point.

"If heat be taken away from water of 38°, then expanſion is the conſequence, and a moderate inclination of the particles towards the rhomboidal form; but this only extends a ſmall way, whilſt the maſs is ſubject to a tremulous motion, ſo as to relieve the obſtructions occaſioned by friction; by the energy of certain affinities, the new form is completed in a moment, and a portion of ice formed; heat is then given out, which retards the ſubſequent formation, till at laſt the whole is congealed. This is the ordinary proceſs of congelation. But if the maſs of water cooled is kept in a ſtate of perfect tranquillity, the gradual approach to the rhomboidal form can be carried much farther; the expanſion goes on according to the uſual manner, and the ſlight friction or adheſion of the particles is ſufficient to counteract the balance of energies in favour of the new formation, till ſome accidental tremor contributes to adjuſt the equilibrium. A ſimilar operation is performed when we lay a piece of iron on a table, and hold a magnet gradually nearer; the proximity of the approach, without contact, is much aſſiſted by guarding againſt any tremulous motion of the table. Hence the reſt of the phenomena are accounted for."

It has been obſerved that freezing and cryſtallization are phenomena of the ſame kind. When ſalts cryſtallize, they uſually contain certain invariable proportions of water. The ſame remark applies to certain acids which congeal when diluted to a certain degree; thus, ſulphuric acid 1.78, ſpecific gravity, congeals about 32°, but does not melt under 45°; whereas an acid more or leſs diluted does not freeze without much greater cold, and when partially frozen, the ice is found to approximate to the ſtrength of 1.78, leaving the unfrozen liquid ſomewhat weaker or ſtronger, according to the circumſtances of the caſe. Nitric acid of 1.30 ſpecific gravity freezes at —2°, according to Mr. Cavendiſh, and no

other ſtrength will freeze at ſo high a temperature. From this concluſion however, we muſt be underſtood to except very dilute acid, ſuch as to be almoſt entirely water. This acidulous water freezes with a leſs degree of cold, and is ſeparated into two portions, the moſt watery part freezing firſt, and afterwards the moſt acid part. This has been called the *aqueous* congelation of the acids. The temperatures at which very dilute acids freeze have been aſcertained by ſir Charles Blagden as under. (Philoſ. Tranſact. 1788.) The ſulphuric acid was of the denſity 1.837, and the nitric acid 1.454. To 100 parts of water by weight were added certain weights of the above acids, and the temperatures at which the mixtures froze were obſerved.

Sulphuric acid.

Water.		Acid.	Freezing point.
100	+	10	24°.5
100	+	20	12°.5
100	+	25	7°.5

Nitric acid.

Water.		Acid.	Freezing point.
100	+	10	22°
100	+	20	10°.5
100	+	23.4	7°.

It appears alſo from ſir Charles Blagden's experiments, that various ſalts diſſolved in water contribute to lower the freezing point; and that the effect of the ſame ſalt is in proportion to its quantity. To 100 parts of water, by weight, were added parts of the different ſalts as under, and the freezing points of the ſolutions found.

Names of ſalts.	Proportion.	Freezing point.
Common ſalt	25	4°
Sal ammoniac	20	8°
Rochelle ſalt	50	21°
Sulphate of magneſia	41.6	25°.5
Nitre	12.5	26°.
Sulphate of iron	41.6	28°.
Sulphate of zinc	33.3	28°.6

Theſe ſolutions may be cooled below their reſpective freezing points, the ſame as water; and the contact of ice in ſuch caſe ſets the congelation a going. It is remarkable alſo, that the expanſion of theſe ſolutions by heat is very different from that of pure waters, eſpecially in the lower temperatures. For other particulars ſee CONGELATION, &c.
